TREATMENT OF CORONARY THROMBOSIS WITH MYOCARDIAL INFARCTION

J. Edwin Wood Jr., M.D., Julian R. Beckwith, M.D.
and
James L. Camp III, M.D., Charlottesville, Va.

Forty-two years ago Dr. J. B. Herrick devoted approximately one minute to treatment in his well-known treatise on sudden coronary artery obstruction,[1] quoted in part here: "If these cases are recognized, the importance of absolute rest in bed for several days is clear. It would seem wiser to use digitalis, strophanthus, or their congeners than to follow routine practice of giving nitroglycerine or allied drugs. The hope for the damaged myocardium lies in the direction of securing a supply of blood through friendly neighboring vessels so as to restore so far as possible its functional integrity." Today, in spite of prolonged and detailed discussions of therapy, myocardial infarction cannot be consistently prevented, and we must still perforce limit our remarks largely to the management of exigent situations arising in its clinical course. This summary statement of therapy of myocardial infarction in the space allotted must be curtailed of necessity, and we will make no attempt to review the many efforts devoted to the etiology and prevention of coronary disease.

To evaluate therapy, some estimation of the severity or extent of the myocardial infarction must be kept in mind. Admittedly, even the smallest and apparently most benign infarction may be in some cases difficult to classify because of its vagaries second to no known disease. Statistically, however, the poor-risk and the good-risk patients can be separated. Two [2] to three [3] days after infarction, the poor-risk patient has been found to have one or more of the following conditions: history of a previous infarction; presence of intractable pain; severe continuing shock; presence of congestive heart failure; occurrence of an arrhythmia, such as auricular paroxysmal tachycardia, auricular fibrillation, auricular flutter, frequent ventricular ectopic beats from more than one focus, ventricular tachycardia, and heart block; history or presence of thromboembolic phenomena; and a greatly enlarged heart. The good-risk patient does not have any of these conditions. As stated, the vagaries and treachery of the disease do not permit exactitude of classification, but a reasonably large study [3] indicates a mortality of 3.4% and a thromboembolism incidence of 1.3% in the good-risk group as contrasted with a mortality of 60% and a thromboembolism incidence of 11.5% in the poor-risk group. Obviously, any argument for or against a given therapy must be brought in line with some such evaluation.

GENERAL CONSIDERATIONS

Before discussion of special features of treatment such as management of shock, anticoagulants, and armchair rest versus strict bed rest, a few already well reviewed axioms may be summarized briefly. Pain must be relieved as promptly as possible. As far as we know, no better drug is available for this purpose than morphine. Meperidine (Demerol) has been recommended, but the analgesic effects of this drug are limited, making it of value only in the milder pain episodes, generally after the first or second day. It is important to remember the anticholinergic effects of the drug and the consequent suppression of the bladder reflex in older men. Occasionally, methadone causes less nausea and vomiting than morphine, but it does not carry the pain-controlling power of morphine. Atropine will not uncommonly relieve pain after full dosage of morphine has apparently failed. This is true when the heart rate is quite slow. Oxygen should be given for dyspnea, cyanosis, shock, or poor pain control, but, after a day or two, in the absence of these signs, it may be annoying to the patient and of no added value. If used under the correct indications it is valuable. When unnecessarily administered it can be a nuisance and a psychological hazard. No rigid rules need be laid down for diet. In the first

few days, liquids and a little toast or zwieback to allay gaseous distention may be all that should be given to ill patients. In good-risk patients and in poor-risk patients who are improving, a low-salt diet of simple foods ranging from 1,000 to 1,400 calories, depending upon the patient and his weight, is advisable over heavier diets. Fluid intake and method of fluid administration depend upon such factors as vomiting, sweating, temperature, and renal function. As a rule, little is gained by a daily fluid intake of over 3,000 cc., and generally 2,000 to 2,500 cc. will suffice. Liquids should not be iced. It goes without saying that heavy liquid petrolatum (mineral oil) and occasional small enemas should be used to make colic elimination as effortless as possible. The commode should replace the bedpan unless shock or debilitation of the patient prevents his using it.

TABLE 1.—*Mortality in Good and Poor-Risk Patients with Myocardial Infarction Treated by the Chair (Up) or Strict Bed Rest (Down) Methods*

	Good Risk	Mortality		Poor Risk	Mortality		Total	Mortality

Up	20	1	5.0	19	2	10.6	39	3	7.7
Down	22	2	9.1	19	4	21.0	41	6	14.7

STRICT BED REST VERSUS CHAIR AND BED REST

Our experience with the chair and bed rest method of management has been salutary and in accord with that of others.[4] We have recently [3] extended these observations to include any differences produced by this method in both the good-risk and poor-risk patients. Table 1 indicates no greater mortality, in fact less, in patients treated with chair rest than in patients on a regimen of strict bed rest. The psychological benefits were obvious in the group allowed to sit up. Observations in table 1 were derived from a study of 80 consecutive hospital admissions classified either as good or poor-risk patients, as stated above. Of the total number of patients (39) allowed to sit up, none were in the 30-39 year age group, 9 were in the 40-49 year age group, 10 were in the 50-59 year age group, 14 were in the 60-69 year age group, 4 were in the 70-79 year age group, and 2 were in the 80-89 year age group. Of the total number of patients (41) treated by strict bed rest, 2 were in the 30-39 year age group, 9 were in the 40-49 year age group, 8 were in the 50-59 year age group, 16 were in the 60-69 year age group, 5 were in the 70-79 year age group, and one was in the 80-89 year age group. The patients who were allowed to sit up were helped or lifted into the chair from the second to the fifth day after infarction, and ambulation was not allowed at any time. Final evaluation of mortality and incidence of such conditions as thromboembolism and arrhythmia, as attributed to either the bed or chair methods, have not been correlated, but this study has uncovered no glaring contraindication to the chair method, and it appears that a large majority of patients with myocardial infarction can be so treated. As a matter of interest we have recently calculated "cardiac work" in patients with myocardial infarction and in other patients in the reclining and sitting position (table 2). The Starr [5] formula was used to estimate stroke volume and the formula suggested by White [6] was used as an estimate for cardiac work. In all but two patients, cardiac work was less in the sitting position; in these two the differences were not significant. More exact studies by Coe,[7] with precise laboratory methods, indicate less cardiac work in the sitting position.

SHOCK

Shock complicating myocardial infarction has been correlated with a fatality rate of 80% or greater.[8] Sampson and Zipser [9] indicate that this rate may be substantially reduced with suitable methods to combat shock, particularly with continuous administration of arterenol by intravenous drip. Here again the survival rate must be influenced to some extent by the nature and degree of the shock. Selzer's [10] realistic approach to this problem and his clinical classification of shock associated with myocardial infarction are clinically recognizable and represent a point of departure for the estimation of therapeutic results. He divides shock in myocardial infarction into four types: type 1, early shock with recovery; type 2, early shock, persistent, with fatal outcome; type 3, shock associated with cardiac arrhythmias; and type 4, late shock with gradual onset and generally fatal outcome. The clinical course of the patient illustrated in figure 1 offers several examples of both type 1 and type 3 shock. This patient had episodes of shock, with recovery after morphine and oxygen, with spontaneous recovery, with recovery from shock following the occurrence and control of arrhythmia, and with prevention of shock by continuous arterenol drip. It is probable that this very ill patient would have survived without arterenol. A decision to use or not to use a pressor amine in borderline shock in a patient with de-

batable blood pressure levels may be reached by determining the amount of urinary flow. Oliguria indicates the necessity for relief of the shock-like state. Disappearance of shock after relief of bradycardia with atropine is graphically illustrated in figure 2. Apparent relief of shock by intravenous transfusion of plasma is illustrated in figure 3. The advantage of arterial transfusion in myocardial shock has not been established. Although it is advisable to administer digitalis whenever congestive failure occurs, as it does often with shock, we have not observed any dramatic change in blood pressure after digitalis therapy alone except after correction of arrhythmia.

In summary, depending on the nature of the shock, therapy may be carried out frequently in this order: relief of pain by morphine and oxygen; administration of atropine for bradycardia; plasma or blood transfusion for collapsed veins; digitalis for congestion; correction of arrhythmia with quinidine, as in auricular fibrillation, paroxysmal tachycardia, or ventricular tachycardia; phenylephrine (Neo-Synephrine) given subcutaneously or intramuscularly as an early measure; and arterenol by intravenous drip for persisting shock. Arterenol administered in 5% glucose solution, generally 4 mcg. per cubic centimeter at 10 to 40 drops per minute, should be withdrawn gradually. Blood pressure depression after sudden withdrawal may be profound. Above all, treatment must be carried out promptly, and, if early measures fail, therapy with arterenol by intravenous drip should be instituted within an hour after onset of severe shock with oliguria.

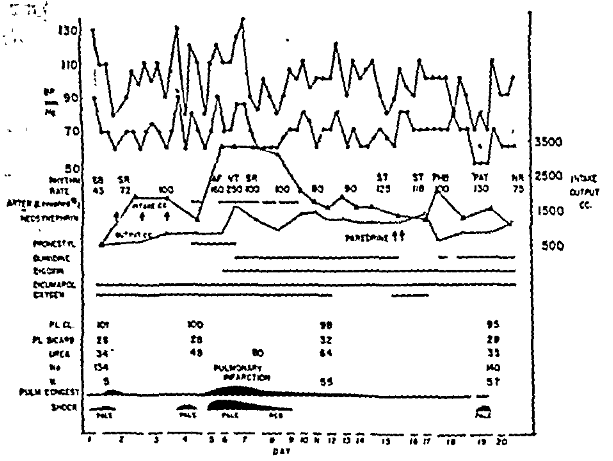

Fig. 1.—Course of patient with eight episodes of sudden blood pressure depression below 90 mm. Hg systolic and three episodes below 80 mm. Hg systolic. Spontaneous recovery apparently followed control of arrhythmia once and correction by arterenol several times. The patient survived and is convalescing at home two months later. AF=auricular fibrillation; VT=ventricular tachycardia; PAT=paroxysmal auricular tachycardia with ectopic focus and sudden onset and offset in spite of slow rate.

ANTICOAGULANT THERAPY

There is no unanimity of opinion as to which patients should receive anticoagulant therapy. It has been recommended that essentially all should receive it,[11] but contrary opinion to this is held.[12] Probably every poor-risk hospitalized patient with myocardial infarction should receive anticoagulant therapy; however, the benefit to be derived from anticoagulants in the good-risk cases is not great, owing to the relatively low mortality and quite low thromboembolic incidence already quoted above. Certainly, when accurate laboratory facilities are lacking for measurement of prothrombin time, it is vastly better to treat good-risk patients by the bed and chair method than to subject them to the hazard of induced hemorrhagic events.

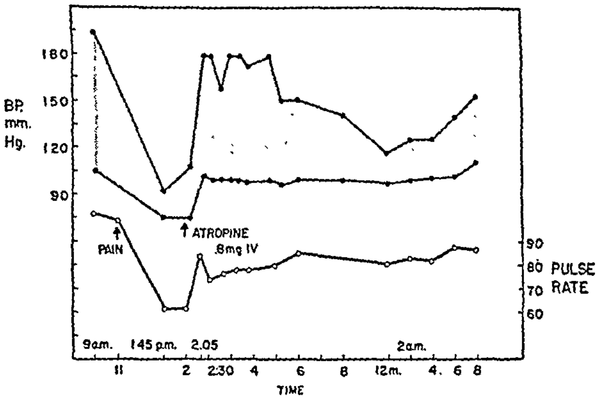

Fig. 2.—Relief of bradycardia and shock after therapy with atropine given intravenously to 49-year-old woman.

The choice of anticoagulants varies. The relative inexpensiveness, the single daily dose, and the wider experience with bishydroxycoumarin (Dicumarol) has made it universally more popular. Recently, phenindione (Hedulin and Danilone) has appeared to offer certain advantages. It produces a therapeutic level of suitably reduced prothrombin time in one to two days[13] as compared to two to four days [13] for bishydroxycoumarin.

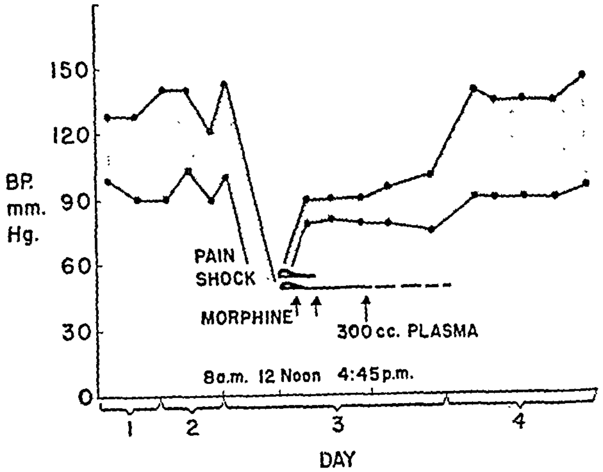

Fig. 3.—Partial recovery from shock, with relief of pain and more rapid rise of blood pressure after intravenous transfusion of plasma, in 59-year-old white man.

Also, phenindione has the advantage of producing a more rapid return to a normal level in the event of undue prolongation of prothrombin time or hemorrhage (two

days or less as compared to an average of five days for bishydroxycoumarin).[13] A single injection of 5 to 10 mg. per kilogram of body weight of vitamin K emulsion restores prothrombin to a near normal range in three hours.[14] We have found phenindione inexpensive and relatively easy to manage with a reasonably constant daily dose. Generally, 100 mg. given orally, twice during the first 24 hours, followed by 50 to 75 mg. twice daily, will produce a therapeutic prothrombin level. Individual variation of course occurs, and a smaller maintenance dosage is sometimes necessary. Liver disease or congestion is always important in considering the dosage of anticoagulants of this type, as are old age and renal insufficiency.

Anticoagulants are, of course, contraindicated in patients prone to bleeding episodes, peptic ulcers, blood dyscrasias with hemorrhagic tendencies, tumors of the gastrointestinal or genitourinary tract, and vitamin K or vitamin C deficiencies. In acute coronary thrombosis with myocardial infarction, unless complicated by additional closure or extension, 21 to 42 days should be a sufficient period for anticoagulant therapy, depending upon the individual patient. The indefinite prolongation of anticoagulant therapy as a preventive measure against future coronary thrombosis [11] is not within the scope of this discussion.

CONGESTIVE FAILURE AND CARDIAC ARRHYTHMIAS

Digitalis should be given in most instances of definite congestive failure with dyspnea, increasing lung moisture, and filling neck veins. There are many patients with myocardial infarction who exhibit basal pulmonary rales early in the illness but whose congestion clears up promptly without medication and with no evidence of progression. There are even a few with mild congestion whose cases are controlled by one or two injections of 1 to 2 cc. of mercaptomerin (Thiomerin). In general, it is better to start digitalis therapy early than late. For rapid digitalization 0.8 mg. of lanatoside C given intravenously and followed in four hours by a similar dose is suitable for emergencies of an acute congestive nature. Digoxin is preferred for oral administration, owing to its rapid excretion rate, allowing relatively prompt escape from toxic symptoms should they occur. Although previous fear of digitalis preparations in myocardial infarction is unjustified,[15] it must be emphasized that digitalis intoxication in patients with myocardial infarction is hazardous and unwise. Noteworthy are the relative tendencies to digitalis intoxication in older persons and the enhanced digitalis effect with potassium deficiency that may sometimes arise from vomiting and lack of food intake in these ill people.[16]

Control of arrhythmias is a matter of constant vigilance and prompt action. The routine use of quinidine does not seem advisable owing to various unfavorable effects, including depression of myocardial function; however, with the development of ventricular premature beats, ventricular tachycardia, or paroxysmal tachycardia, immediate and continued preventive therapy is indicated. In auricular flutter and fibrillation, digitalization should precede the use of quinidine to restore normal rhythm. Control of ventricular tachycardia by either quinidine or procainamide hydrochloride is a matter of trial. In the patient in figure 3, 250 mg. of procainamide hydrochloride, given intramuscularly every four hours, appeared to control ventricular ectopic beats and ventricular tachycardia but was subsequently of little aid against auricular fibrillation and paroxysmal tachycardia. Procainamide hydrochloride is effective in ventricular premature contractions in doses of 250 to 500 mg. given orally every four to six hours. Quinidine is by far the drug of choice in supraventricular arrhythmias and often may be superior in ventricular tachycardia as well.

The development of high grades of atrioventricular block with posterior infarction is an unwelcome and unfavorable state. Occasionally use of ephedrine is justified in breaking up repeated episodes of Adams-Stokes syndrome, but the dreaded sequence of complete heart block with temporary ventricular asystole followed by ventricular tachycardia is a triad of events resistant to any therapy, unless it occasionally responds to atropine. Fortunately, a few patients with marked bradycardia and lesser grades of atrioventricular block respond to the proper use of this drug.

SUMMARY

The management of coronary thrombosis with myocardial infarction has expanded considerably over the years and varies with each patient. Treatment by the bed and chair method is acceptable and salutary in many instances without increased cardiac work in the chair position, except in certain circumstances. Therapy for shock varies and may consist of any one of several methods or a suitable combination of them. Arterenol is required not infrequently in sustained shock that is not otherwise controlled. Anticoagulant therapy is desirable in most instances of myocardial infarction, and phenindione seems to be a more satisfactory anticoagulant at this time. Early control of progressive congestive heart failure is important. Prevention or control of paroxysmal or sustained arrhythmias in myocardial infarction is imperative.

Estimating Radiologic Hazards.—To evaluate reports of monitors surveying a station in terms of existing radiologic hazards to personnel, the officer-in-charge must know the maximum radiation dosage allowed for any person; . . . the dosage personnel have already received; the effects of varying amounts of radiation on personnel; the existing dose rate of radiation in the area; and a ready, simple method for accurately and rapidly estimating the radiologic situation. With this information . . . the officer-in-charge can quickly determine whether to permit personnel to remain in the area; the period of time personnel may continue working in the area; the time when personnel should leave the area; whether personnel may safely enter another area; and how operations in a radiologically contaminated area might be continued by the proper rotation of personnel.—Commander R. P. Nadbath (MC), U. S. N., Some Rules of Thumb in Estimating Radiologic Hazards, *United States Armed Forces Medical Journal,* August, 1955.

VENOUS HUM IN CARDIAC AUSCULTATION

Dale Groom, M.D., John A. Boone, M.D.
and
Margaret Jenkins, M.D., Charleston, S. C.

The venous hum, a continuous murmur usually of maximum intensity in the supraclavicular area, is a common auscultatory finding. Heard particularly in children, it is of no known pathological significance. Its importance lies rather in its often close resemblance, because of its continuous or predominantly diastolic characteristic, to pathological murmurs. Our interest in the venous hum stems from the observation of numerous patients in the cardiology and pediatric clinics of the Medical College of South Carolina, in whom the murmur was transmitted down to various areas of the precordium where its presence was of concern in auscultation.

In this presentation the clinical features of venous hum are discussed as they pertain to cardiac auscultation. Emphasis is placed on procedures that permit the differentiation of this murmur from murmurs of pathological significance on the basis of clinical findings alone.

Most present-day textbooks of cardiology and pediatrics give brief, if any, mention of venous hum. In the older literature it received considerably more attention and was, in fact, one of the earliest recorded auscultatory findings. Laennec [1] seems to have been describing the venous hum (which he believed to arise in the carotid arteries) when he wrote "Sometimes . . . particularly when seated in the carotids, the thrill is much more extended than the diameter of the artery, and seems more superficial; it is sometimes perceptible over a space of two inches in breadth on the side of the neck. In this case the thrill is continuous and without any pulsative momentum; and its sphere seems more extended, the lighter the pressure is made with the finger." He notes later a case of an adult in whom the sound could be heard only in one position, having ". . . no thrill or bellows-sound in the heart or arteries when lying down, or sitting up in the usual manner; but if he raised himself in bed supporting himself on his elbow, a slight but very distinct purring thrill and also bellows-sound became perceptible over the extent of an inch square, a little above the right clavicle. . . ." Laennec described clearly the to and fro nature of the continuous murmur ". . . as if the artery were become a vibrating string, from which two or three notes were drawn out in succession, by advancing and drawing back the finger upon it." His observation that the murmur occasionally has a musical quality is picturesque: "In four cases I have met with this sound (which is literally musical) in the carotid arteries. In one of these cases, I at first conceived the sound to arise from an instrument in the apartment below. On a close examination it was found, that the musical notes were associated with a slight vibration of the artery, which, during its diastole, seemed to brush the edge of the stethoscope."

During the 1830's in England Hope [2] made careful clinical studies of "the loud murmur of the internal jugulars." He demonstrated that its origin was venous rather than arterial as Laennec had supposed: "On depressing the finger with sufficient force to obliterate the vein, without obliterating the carotid artery, the continuous murmur, together with the musical notes, instantly cease: which is conclusive proof that both are seated in the vein." His theory as to actual method of genesis of the sound seems as reasonable as any, that "in order to produce the murmur of the internal jugular in perfection, it was necessary to avert the face while the neck was kept perpendicular and the chin well raised. The mode in which this position acts is, in my opinion, by placing the vessel in a moderate state of tension, which is favorable to the vibration of its walls, and also increases the sonorous effect of pressure accidentally exercised on it at any particular point, as, for instance, by the sternomastoid muscle where it crosses in front of the vein. Accordingly, when the head is restored to its natural position, or is depressed, the vein is relaxed and the murmur ceases or greatly diminishes." Hope also noted that "the venous murmur is on a much lower key than the arterial bellows murmur," that it "experiences augmentations corresponding with each arterial diastole," that it "becomes louder during inspiration,—especially about its end, and weaker during expiration," and that "by the adroit management of pressure with the stethoscope over or near large veins, the venous murmur may often be raised by a gradual swell, into a more or less musical hum, such as is yielded by a child's humming top." Hope then added, "I propose to denominate this the *Venous Hum.*" There is little to add to these clinical descriptions of more than a hundred years ago.

The prevalence of venous hums in children was investigated by Landis and Kaufman [3] in a 1912 study in which they reported finding it in 84 of 99 children under 15 years of age examined at the Phipps Institute. In all it was described as a continuous murmur heard in the erect position and diminishing or, usually, disappearing completely in the recumbent position. Of the 84 cases it was heard loudest on the right side of the neck in 42, on the left in 17, and equally loud on both sides in 25. They felt that, contrary to the opinion of some of the earlier writers, the murmur had no definite relationship to anemia except, perhaps, that in anemic individuals there was perhaps less tendency for the sound to disappear on recumbency. It was their contention that "the venous hum

is present in the majority of children under 15 years of age, tending to diminish in frequency as that age is reached, and finally disappearing."

The auscultatory pitfall of mistaking a venous hum for a murmur of pathological significance was pointed up by Palmer and White [4] in 1928 when they reviewed 14 cases referred for cardiac evaluation. They stressed the frequency with which the venous murmur appears at the precordium, transmitted downward from its site of origin, and its characteristic similarity to the continuous murmur of patent ductus arteriosus.

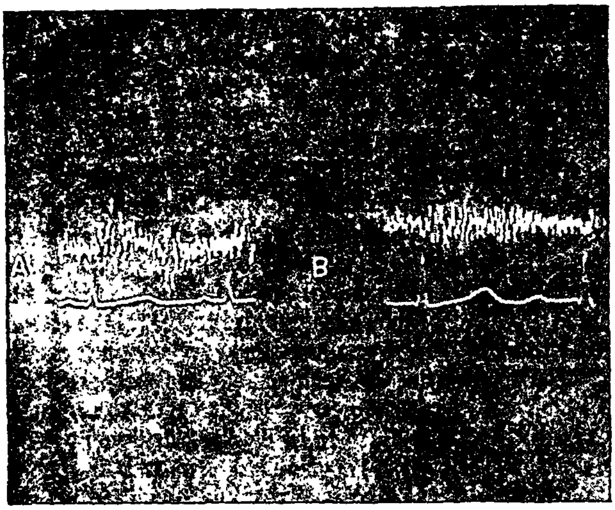

Fig. 1.—Oscilloscopic sound recordings (above) with simultaneous electrocardiograms (below) of two continuous murmurs. *A*, venous hum recorded from the precordium of a child aged 7. Murmur was of grade 4 intensity at the right supraclavicular fossa and about grade 2 at the aortic area. *B*, murmur of patent ductus arteriosus in a child aged 8. Note greater amplitude during systole, with gradual decrescendo after second heart sound (tall, upward peak at approximately mid cycle). Murmur was of maximum intensity in second and third left intercostal spaces—region from which this recording was made.

Of 250 children examined in Sweden, Graf, Moller, and Mannheimer [5] found a venous hum in well over 50% under the age of 9, the incidence decreasing to about 30% at 12 to 15 years of age. In their series it was no more frequent on the right than the left side of the neck and could be heard equally well on both sides in half the cases. They likewise cited the continuous nature of the murmur, its accentuation on inspiration and on turning the head to the opposite side, its obliteration by jugular compression, and its maximum intensity at "the triangle of Sedillot, . . . the angle between the clavicle and the insertion of the sterno-cleido-mastoid muscle." In addition to this clinical study they measured the sound frequencies in 40 cases as recorded by a system of "calibrated phonocardiography." Their results indicated that, in a venous hum, "the amplitude most often has its maximum in the frequency range of 50-175 cycles per second and often reaches 500 cycles per second."

Taussig [6] in her book on congenital heart disease stresses the diastolic accentuation of venous hum. Its differentiation from the murmur of patent ductus arteriosus is aided by "the most characteristic of all features of the venous hum . . . its change in intensity with changes in position of the head and neck."

Our own study of the venous hum has not been a statistical one. We have not attempted to ascertain its incidence among patients admitted to the pediatric and outpatient clinics of the Medical College of South Carolina, but it is our impression that the incidence of a venous hum of sufficient intensity to be heard on careful auscultation of the entire precordial area is somewhat less than the incidence of an audible venous hum in the neck. We have, rather, attempted to study some characteristics of the sound itself in a group of 14 patients, all under 10 years of age, seen at this institution during a two month period. In most of these patients the hum was discovered as an incidental finding on routine physical examination. In a few cases cardiac evaluation had been requested, presumably on the basis of this auscultatory finding.

METHODS

Graphic recordings were made of the sounds as displayed on the screen of a double-beam cathode ray oscilloscope employing a method described in a previous report.[7] By means of varying the recording (sweep) speed, two time-scales were used, one comparable to that of the phonocardiogram and the other a much faster speed revealing the wave forms and component frequencies of the sounds in detail.

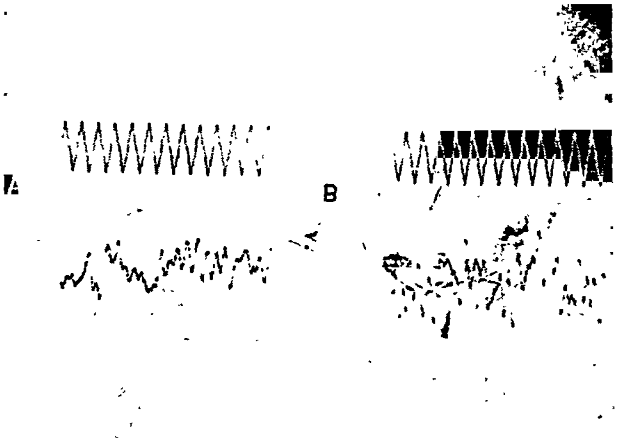

Fig. 2.—Portions of venous hum of figure 1*A* recorded oscilloscopically with expanded time scale to show greater detail of sound wave form. Both that at *A*, from systolic phase, and that at *B*, from the diastolic phase of the murmur, were made at same amplification with electronic pickup placed over right supraclavicular fossa. In diastolic phase sound is of greater amplitude and contains greater proportion of higher frequencies, both factors serving to produce accentuation of murmur during diastole.

An electronic heart sound pickup,[8] recently developed in collaboration with the General Motors Research Laboratories, was used in direct contact with the body surface in place of a conventional phonocardiographic microphone. The pickup was designed primarily for low

(subaudible) frequency recording but has a useful range of 2 to 500 cps. In order to selectively emphasize frequencies in the audible range—those that compose the actual sounds heard on auscultation—low frequencies were attenuated by means of filters in the electronic amamplifier so that, e. g., all those below 30 cps appear in these tracings at less than 15% of their actual amplitude. Otherwise the relatively slow movements of venous and carotid pulsation would obliterate the much smaller sound vibrations. Such filtering is of course not essential with the use of ordinary microphone pickups that are themselves insensitive to very low frequencies.

SOUND TRACINGS

The continuous nature of the venous hum murmur is illustrated in figure 1*A*, recorded from the aortic area of the precordium of a child aged 7. This is a slow-speed recording with the simultaneous electrocardiogram below for purposes of timing. Some increase in amplitude of the murmur is observable during diastole, though this small difference is probably a minor factor in producing what to the ear is a prominent diastolic accentuation of the sound. Figure 1*B* shows in contrast systolic accentuation of another continuous murmur, that of patent ductus arteriosus in a child aged 8. The two murmurs appear—and sound—otherwise quite similar.

In figure 2 portions of the same venous hum as recorded from the right supraclavicular area are expanded in time so that each trace represents 0.13 second. A triangular wave form of 100 cps frequency is included above as a time reference. Figure 2*A*, part of the systolic phase of the hum, is essentially a noise type of pattern, like that of most heart murmurs, and is made up predominently of an irregular assortment of frequencies on the order of 50 to 100 cps with a few as high as 200 cps.

A diastolic portion of the hum, made at the same amplification, is depicted in figure 2*B*. It is seen to differ from the systolic sound in that it contains many prominent waves of higher frequency, ranging up to 250 cps, as well as being of somewhat greater over-all amplitude. In addition there are runs of more regular vibrations, tending to have a sinusoidal type of wave form, a characteristic that was perceptible on auscultation as a certain musical quality in the hum. Doubtless the greater proportion of these higher frequencies, to which the ear is far more sensitive, is another reason for the audible accentuation during diastole.

CLINICAL CHARACTERISTICS

The venous hum, a common auscultatory finding in children, is frequently transmitted to the precordium where it may be heard with considerable intensity at the aortic and pulmonic areas, and occasionally as far down as the apex. Its point of maximum intensity is, however, readily traceable to the supraclavicular fossa, at a site approximately overlying the internal jugular vein, on one or both sides. Unlike the murmur of patent ductus arteriosus, which it resembles superfically, the venous hum has a diastolic rather than a systolic accentuation. Its frequency, and hence its pitch, tends to be higher during the diastolic phase, often with some degree of musical quality.

The following characteristic features of venous hum are of value in differentiating it from murmurs of pathological significance on clinical grounds alone. 1. It is louder with the subject in the sitting or erect position and diminishes or, usually, disappears altogether in recumbency. 2. When the stethoscope is placed at the point of maximum intensity over the jugular vein, light pressure tends to increase intensity of the murmur while heavy pressure abolishes the sound. 3. On auscultation over the precordium, firm pressure with the finger on one or both jugular veins will cause a murmur due to venous hum to disappear completely. 4. Turning the subject's head away from the side of origin of a venous hum increases the murmur's intensity. The effectiveness of this maneuver is greater if the chin is raised rather than lowered. In some subjects presence of a hum is dependent upon this position, and in most subjects it disappears when the head is turned toward the side of origin. It should be borne in mind that not infrequently venous hums arise in both sides of the neck, the quality of their sounds sometimes differing on the two sides. 5. Careful auscultation will usually reveal that a venous hum is more prominent during inspiration than during expiration. 6. Other postural changes, particularly those of the pectoral girdle as produced by weight-bearing on the arms, often have a marked (but less predictable) effect in producing or abolishing a hum.

Auscultatory characteristics of venous hums are more variable. Some tend to be more rough or groaning in character, especially their systolic components, while others are of higher pitch, of a musical, squeaking, or even blowing nature. The former types are usually heard best with a bell stethoscope, because of the attenuation of lower frequencies encountered in use of a diaphragm-type chest piece. The venous hum sound can simulate to a remarkable degree many murmurs of intracardiac origin, a consideration that merits occasional reemphasis in its bearing on cardiac auscultation.

SUMMARY

The venous hum, a physiological extracardiac murmur heard in a high percentage of children and in some adults, is characteristically a continuous murmur with accentuation during diastole. From its point of maximum intensity in one or both supraclavicular fossae, it is frequently transmitted downward over the precordium, where it may simulate remarkably murmurs of pathological significance.

16 Lucas St. (16) (Dr. Groom).

Foetor Hepaticus.—The breath of patients with severe parenchymal liver disease often has a characteristic odor, foetor hepaticus. . . . Attempts to isolate from the breath the compound producing the foetor have failed because of the very small quantities involved and the difficulty of getting a seriously ill patient to breathe against the resistance of a collecting system. . . . In patients with a strong oral foetor a very similar smell may be present in the urine. . . . Methyl mercaptan was isolated from the urine of a patient with massive hepatic necrosis; some dimethyl disulphide was probably also present. It might be expected that, in the body, methyl mercaptan would be either oxidized to dimethyl disulphide or methylated to dimethyl sulphide. We believe that foetor hepaticus is caused by the elimination of one or more of these compounds in the breath. Little is known of the pharmacology of these compounds, but by analogy with closely related compounds they may well be toxic.—F. Challenger, M.D., and J. M. Walshe, M.D., Foetor Hepaticus, *Lancet,* June 18, 1955.

THE COMPENSATION PATIENT AND THE PHYSICIAN

Jesse T. Nicholson, M.D., Philadelphia

The care of the compensation patient by the physician presents a series of events that may result in an uncooperative patient, prolonged patient disability, an unpleasant association for hospital personnel, an unappreciative employer, and a dissatisfied insurance company. Many physicians have experienced upon arrival at their office a secretary confronting them with, "Mr. Doe, of the X. Y. Z. Insurance Company, has phoned twice this morning. He wishes to speak with you right away about a patient that was admitted last night to the hospital on your service." The physician is an hour late for appointments. The fractured hip that was added to his morning operative schedule took two and one-half hours to pin. Mr. Doe's insurance case was the one patient he did not see; the resident had said, "A fracture of the os calcis was admitted last night."

THE CLAIM AGENT

The physician decides, "Let Mr. Doe blow!" but, as he skirts the corridor of the waiting room to reach the first examining room, he is trapped. Mr. Doe has squirmed by the receptionist. "Oh, doctor, just a minute," says Mr. Doe. "I phoned you at the hospital this morning while you were operating. Since I had an errand in this office building, I thought I could catch you. What will be the total disability of Abraham Zopolski, who fell down that elevator shaft last night? How long will he be in the hospital? Will you have to do an open operation on him? Will he have any permanent partial disability? How much physical therapy will be needed?" Fortunately, the physician remembers that the waiting room is loaded with patients. He does not explode. He replies, "I'll send you a report on Zopolski this evening." To his surprise, the young man now asks, "Doctor, about Henderson, who got that infection after the intramedullary nailing of his femur. How much will his hospitalization be prolonged?" Mr. Doe, the young man who has given the physician such a bad time, is a claim investigator for one of the insurance firms that underwrite compensation insurance for employers. Compensation insurance is a necessary protection for an employer and an employee. Physicians carry it for their office employees. They realize the advantage of having private insurance firms handle compensation insurance, since the only alternative would be state or government provision for compensation, with a staggering increase in the budget that the physician as a taxpayer would subsidize.

The physician appreciates that all free enterprise, including private and mutual insurance companies, survives by competition. At least the companies must do some part of the job better than their competitors. This edge could be excellent public relations or having aggressive claim agents that bear right down on the physician. The latter may be the secret of survival of the X. Y. Z. Insurance Company. Mr. Doe, their representative, is, we assume, a typical claim agent who recently started with the regional office of the insurance company. In the claims department he has been imbued with the urgency of learning at once of an accident involving an insured person and immediately obtaining information that will determine the total cost of medical care and permanent disability, so that funds may be laid aside by the insurance firm to take care of the insured person. This is important for the insurance company since many premiums are issued on a month-to-month or short-term basis. If an employer has a number of accidents in a given month, his next premium must be raised to cover the cost of care for the injuries. The cost then can be spread over several months subsequent to the month of injury. If, however, the extent of total disability and the period of hospital care, follow-up treatment, and permanent partial disability are not realized and apportioned over a period of time, the insurance company must either dig into its reserve funds or borrow. Either procedure is costly to the company. The employer, on the other hand, who has been working on a budget or contract will be equally embarrassed for funds if his premium is raised to cover costs a month or two before his contract job or fiscal year ends.

It is not my purpose to absolve liability companies. It is my wish to make the physicians' contacts with the compensation patient less arduous. For example, there should be no necessity for Mr. Doe to intercept a physician at any time during the day to inquire about a patient under his care. We are trained physicians; our primary interest has been in the rehabilitation of the sick and injured. The majority of us have specialized in a particular branch of medicine in order that we could concentrate on improving the care of patients in a particular field. We are authorities on Mr. Zopolski's injury. We cannot estimate to the day when he will go back to work, but we can give a preliminary estimate that would not be far off, and we can prognosticate that he will have a permanent partial disability. Compensation companies provide forms requesting information. These are believed simpler means of communication than a letter. We detest forms of all types. Insurance forms are, therefore, no exception. But, we all accept the fact that a physician who refers a patient to us expects a report of our examination, and it is even customary to send him progress reports. Completion of a compensation insurance form is less troublesome than writing a letter. It frequently can be handled by a secretary; in this way we could avoid Mr. Doe's interruptions.

INADEQUATE HANDLING OF COMPENSATION PATIENTS

We as physicians are prone to take exception to the compensation patient's attitude. We regard him as lacking confidence, being unappreciative, exaggerating his disability, and being uncooperative. Undoubtedly, many confusing thoughts occur to the patient during the sequence of events that follow an accident. The injured

---

Chairman's address, read before the section on Orthopedic Surgery at the 104th Annual Meeting of the American Medical Association, Atlantic City, June 8, 1955.

Mr. Zopolski is taken to the plant first-aid station, and the doctor, nurse, or first-aid team evaluate his injury and apply a splint. His family is called, but his family physician is rarely notified. It may be taken for granted that he has none. He is sent to a certain hospital because the plant doctor works there, or the insurance doctor works there, or because the plant has endowed beds at the hospital. He may be seen in the accident ward by a disinterested intern or resident. This disinterest may be the result of a policy of the hospital of assigning industrial cases to a particular Dr. Jones. At other times, the patient may be seen by a resident who is a perfectionist and who criticizes the poor splint and the plant doctors. This may be followed by a discussion of surgical care or procedures that are at variance with those utilized by the physician in charge. Too frequently a physician is prone to say, "We'll give you a little gas and fix you right up." The patient will have the impression that modern medical science is as depicted in the comic books. He, therefore, expects an immediate restoration. As he recovers from anesthesia, however, he is completely overwhelmed and sure that some catastrophe has befallen him. He awakes with nausea, headache, and at times more pain in his leg than he had before operation. Then he observes his leg is hung from a "torture rack" by ropes. When he learns that the cast is on for weeks, he is sure he has been "fouled up." No one recalls "Dick Tracy" in a cast for more than two days, and "Flash Gordon" is always restored by the following morning.

The psychological effects on the patient in the hospital are varied. The worry associated with loss of earning power, the time payments on the automobile, the separation from home, and the possibility of loss of job because of residual disability are to be considered disturbing, to say the least. The worry may be lessened by the social service department's arranging for visits by family and friends. It is also important that the patient be kept busy. Some form of occupational therapy is essential. Some type of physical therapy can always be instituted. Most patients regard exercise as work, but they live by it; therefore, the therapist should give them a routine to follow. The patient's injury may be the resident's problem, but the physician should make it his as well. He should see him on rounds, stop and speak with him, and not let him get the impression he is ignored by the physician and his questions are not answered or that the physician suspects he is not capable of understanding. The physician should explain that the patient will have to have his fracture reduced under anesthesia and that the reduction will be held by metal pins fixed in a plaster cast extending from the toe to the groin. If the possibility of a subtalar arthrodesis is imminent, he should tell him an open operation will then be possible in six to eight weeks and he will be out of work six months. The physician should tell him about when he will go home, when he will use crutches, when he must return to the hospital for a cast change, and when he will have a walker applied to his cast. If this is left to others, it may be neglected, and discontent will build up in the patient's mind.

ADVANTAGES OF A CONSULTATION

Physicians may be responsible for prolonging a patient's hospitalization, delaying his recovery, and increasing his permanent partial disability. This is prone to occur when they undertake the management of an injury with which they have not had sufficient experience. This is noticed particularly in open fractures and in fractures involving joints. Too many surgeons hesitate to request a consultation for a complicated fracture. Instead, they thumb the leaves of a textbook on fractures, or worse, read the second-class mail brochures advertising a particular piece of apparatus in which are shown reproductions of the roentgen films with the apparatus maintaining an infallible position of the fracture. Unfortunately, the brochure never warns of the appalling complications that may occur. These complications were graphically demonstrated by Dr. Charles N. Pease [1] in his chairman's address last year. No insurance carrier will question the need for a consultation, unless the physician has neglected to tell them of the consultation before the consultant presents his bill. At times the physician may be confronted with a request by an insurance company for a consultation with another physician. He should simply remember this was probably inspired by a consultant for the company who, after reviewing the hospital course and the x-ray films, believed the physician might wish to be spared getting into difficulty just as much as he desired to prevent the patient's attaining a greater disability. It may be surprising to some physicians to learn that many physicians resent the suggestion of a consultation even when the problem is in the specialty of a fellow member of their hospital staff. Too well do we know if it were a member of their family how changed their attitude would be. We have cause to wonder at times what sort of an alter ego develops in the physician looking after an industrial case; perhaps it is his fear of losing the case.

There are instances where physicians refuse to give any information to the insurance company in regard to a patient's condition. The first communication from the physician to the insurance company may be his bill for medical care. What is behind his reasoning? Does he believe all insurance reports unnecessary? Does he believe any communication will promote lay interference with the management of his patient? Has he been told by the patient's attorney not to give any information to the insurer? This physician cannot appreciate that the insurance company stays in business because it pays for good medical care. The insured employer would not continue to pay premiums to an insurance company that caused dissatisfaction among his disabled employees. The insurance company acts in the capacity of a guardian for the disabled employee. It has every right to know the answers to the questions of the Mr. Doe previously mentioned. The answers are necessary to enable the company to set aside funds to cover the medical expenses. As for the patient's attorney, he may have a right to ask that information be withheld if there is a third party involved; for example, if the patient was driving a bakery truck that was struck by a "hot rod" but not if the insurance company accepted the case as being one of injuries sustained in line of employment. In the latter case, they are then paying the hospital bills and the physician's bill and, therefore, are entitled to what information the physician can give them. The physician must also be aware that, in cases in which a third party is involved, the lawyer representing the patient desires to build up medical expenses to impress a jury. The lawyer, therefore, may insist upon the doctor's obtaining laboratory studies and consultations that are costly and unnecessary. The studies, incidentally, are charged to the insurance company that is paying for the patient's care.

---

[1] Pease, C. N.: A Critical Analysis of the Fracture Problem, J. A. M. A. **156:** 805 (Oct. 30) 1954.

ESTIMATING PERIOD OF DISABILITY

There is a great tendency for the physician to be optimistic in regard to his proved surgical abilities. A report to an insurance company showing a disability period estimated upon the minimum possible recovery period can backfire. A compensation patient upon return to work is generally expected to do the same job he did prior to his injury. This job is frequently a laborious one. If the physical conditioning of the patient was not complete before he returned to work, he will either voluntarily quit or be asked to quit because he cannot do his share of work. Then the doctor will be confronted with convincing Mr. Zopolski that he is only having conditioning pains and that by working he will get over them. Mr. Zopolski fails to be convinced and frequently finds a more sympathetic friend in the legal profession who knows a medical colleague of the physician who has a different evaluation of pain. Next the doctor finds himself before a compensation referee trying to explain pain that is disabling and pain that is not disabling.

While the claims investigator for the insurance company may have been impressed with the preliminary report of estimated disability, he now finds that he failed to advise sufficient funds to continue Mr. Zopolski's rehabilitation. Rarely do compensation patients follow a textbook formula. It is a good plan to prepare the insurance company by adding 20% to what is at first anticipated as time of total disability. In this way the insurance company and doctor are saved a poor estimation.

MORE PERSONAL PHYSICIAN-PATIENT RELATIONSHIP

When Zopolski, in the physician's opinion, is ready for work, he should discuss it with the patient. If the physician does not think he can return, his activity in occupational therapy and physical therapy should be stepped up or he should be given such a program and the physician should arrange to talk with him again in two weeks. The physician should not just write the insurance company saying Zolpolski has attained his maximum improvement; he has 50% disability of his foot; he requires no further treatment; he may return to work. This is a sure formula to send Zopolski to a lawyer and to force the physician into compensation court for a hearing before the referee. First, the physician should take time to tell Zopolski that he thinks he can try going back to work, that he believes he will continue to improve while at work as rapidly as he will continuing with physical therapy and occupational therapy, and that he realizes he will get a better pay check by going to work than he is getting for disability. The physician can say he is recommending that the insurance company pay him partial disability for 50% loss of function of his foot. He can tell him this amount may even prove to be too high or, possibly, not enough, but the true permanent partial disability can be determined better after he has worked three months or six months. If, on the other hand, the man were a structural steel worker and were to retain a 50% loss of his foot and but 45 degree motion of the knee, it would obviously be unsafe for him to consider his previous work. He should have been told some months before he had attained maximum medical restoration that he could not go back to structural steel work. He should have had an opportunity to express what other work he was fitted to do and believed he could possibly do with a stiff foot and a knee that would not permit him to climb or kneel. Efforts should have been made to prepare him, at least mentally, physically, and technically for a different type of work while he was under treatment.

EVALUATING PERCENTAGE OF DISABILITY

The method of evaluation of permanent partial disability of a compensation patient varies in different states. Generally, it is on the basis of percentage of the part, as hand, foot, leg, or arm, or on the basis of percentage of the body as a whole. In New York state, the physician in charge of the compensation patient is merely asked if the subject has or has not disability. If disability is proved, the percentage of disability is determined by physicians employed by the bureau of workmen's compensation. There are a few ways, however, that a physician might be prejudiced in his opinion of disability. The evaluation of his surgical result is often quite optimistic. The evaluation of the disability of a member of his family or a friend may be a bit pessimistic. In such situations, to avoid critical implications, it would be wise to have an evaluation of disability by a consultant. A physician must also guard against his opinion of disability being influenced when his fee is contingent upon an award to the claimant. In these cases, the claimant generally has a lawyer who may be working on such a basis. This lawyer, however, should not be permitted to place a member of the medical profession in a position subject to fee influence. The fee should be arranged prior to the examination. While most of us dislike being called before a referee, we should feel an obligation to give testimony for either claimant or defendant. If we felt this obligation more strongly we could remedy the stigma of "claimant's witness" or "insurance witness" that is too frequently attached to our colleagues.

The evaluation of a claimant's disability is a remarkable guess on the part of most physicians. This guessing can reach extremes. Two orthopedic surgeons, Drs. A. and B., with similar training, board certified, and working in the same city, testified before a federal referee that a stevedore with a healed patellar fracture had disability of the knee, according to Dr. A. (for the insurance company) 15%, and according to Dr. B. (for the claimant) 85%. It is not possible that prejudice can influence thinking to such an extent. It is possible that they were inexperienced. Resident training programs rarely touch on evaluation of disability. Certainly, if the residents had better training, such discrepancies would be less likely to occur. It is such discrepancies that take decisions that should be made by physicians out of their hands and put them in the hands of laymen. The decisions on disability, in most hospitals, are made by a junior staff member who is assigned to the industrial or compensation clinic. The residents are spared this chore because of their lack of experience and the danger of getting their chiefs into compensation court and because they are not interested. Why should it not be interesting? We teach residents to determine joint motion, both in diagnosis and in evaluation of end-result. Why should we not encourage them to do a little mathematics and determine the percentage of function loss? A few training programs carry this out with their fracture evaluations but seldom as a routine with patients recovering from compensable musculoskeletal lesions.

SUMMARY AND CONCLUSIONS

The compensation patient and the physician would have fewer problems if these recommendations were followed: 1. The insurance company should be regarded as the responsible guardian. 2. The same physician-patient relationship should prevail with the compensation patient as with other patients. 3. The family physician should not be ignored. 4. Consultations should be requested as freely as for other patients. 5. Underevaluation of disability should be considered more difficult to correct than overevaluation. 6. The patient should be informed by the physician in charge of his recommended disability rating. 7. The physician should request a consultant's opinion on disability rating rather than permit personal interests to influence his opinion. 8. The physician's appearance in compensation court should be an accepted responsibility in order to reduce instances of "claimant's witness" or "defendant's witness." 9. Disability evaluation should be included in the resident specialty training programs.

PREDNISONE AND PREDNISOLONE AS THERAPEUTIC AGENTS

PROGRESS REPORT ON THEIR INTEGRATION INTO GENERAL MEDICAL PRACTICE

Tom D. Spies, M.D., Robert E. Stone, M.D., Birmingham, Ala., Guillermo García López, M.D., Carlos M. Díaz Tellechea, M.D., Rubén López Toca, M.D., Alfredo Reboredo, M.D., Havana, Cuba
and
Ramón M. Suárez Sr., M.D., Santurce, Puerto Rico

The discovery of each new therapeutic agent is a challenge to the medical profession. When the judicious use of these agents may mean the difference between a useful life and a useless life and between a long life and an early death, the responsibility on the physician is overwhelming. Prednisone and prednisolone are two such agents. They are the chemical analogues of cortisone and hydrocortisone, respectively, and the chemical relations are shown in figure 1. Prednisone was formerly known as metacortandracin and prednisolone as metacortandralone. When given systemically in sufficient amounts, they have the same antirheumatic, anti-inflammatory, and antiallergic effectiveness as pituitary corticotropin (ACTH), cortisone, and hydrocortisone. As can be seen in figure 2, freedom from sodium retention is impressive. Also note in figure 2 that, following the use of cortisone, sodium excretion decreased and body weight tended to increase. The tendency to retain sodium is extremely variable from person to person under cortisone, hydrocortisone, or pituitary corticotropin therapy. At times it is a limiting factor, and in those instances the new steroids can be used to great advantage. These two new steroids, when given in toxic amounts, produce the other metabolic effects (so-called side-effects) caused by overdosage of the older steroids used as therapeutic agents. Some people are predisposed to alterations of the gastrointestinal tract, and whether pituitary corticotropin and the corticosteroids make this worse has not been fully determined. It is known, however, that perforation of ulcers can occur in persons while they are under heavy therapy with these materials even though they have no symptoms.

When pituitary corticotropin is injected into a person with normally functioning adrenals, the steroid hydrocortisone, shown in figure 1, and many other substances are promptly produced. As every physician knows, adrenal cortical hypofunction (Addison's disease) is due to lack of adrenal cortical tissue. When adrenal cortical tissue is absent, the injection of corticotropin obviously fails to produce any adrenal steroids. It is noteworthy that, when adrenal cortical tissue is absent, patients do not have symptoms of arthritis or other diseases that can be ameliorated by the use of selected adrenal steroids. It is most important to stress that, in the com-

Dick Foundation of Chicago, and the Illinois Health Foundation of Chicago. *The studies in Cuba were aided by grants from the Comité* de Damas of the Hospital General Calixto García of Havana, Cuba. *The studies in Puerto Rico were aided by grants from the Fundación de* Investigaciones Clínicas of Santurce, Puerto Rico.

The prednisone used in this study was furnished by Dr. Edward Henderson of Schering Corporation, Bloomfield, N. J., Dr. Elmer Alpert of Merck & Co., Inc., Rahway, N. J., and Dr. C. J. O'Donovan of the Upjohn Company, Kalamazoo, Mich. Prednisolone was furnished by Dr. Michael Carlozzi of Pfizer Laboratories, Brooklyn, N. Y., Dr. Edward Henderson of Schering Corporation, Dr. Elmer Alpert of Merck & Co., Inc., and Dr. C. J. O'Donovan of the Upjohn Company.

Electrolyte determinations were done by William Niedermeier and Henry A. Spies Jr.

plete absence of adrenal cortical tissue, relatively small amounts, 12 to 15 mg., of the steroids shown in figure 1 can be effective in relieving the symptoms of adrenal cortical hypofunction. In recent years it has been shown that either pituitary corticotropin or certain of the adrenal steroids, when given in unphysiological doses, can be lifesaving in treating many diseases. With each of these materials we have had sufficient experience to state that we consider them the therapeutic agents of choice in many conditions, such as severe cases of pemphigus vulgaris, acute disseminated lupus erythematosus, acute exfoliative dermatoses, acute drug eruptions, acute urticarial reactions, acute allergic reactions to therapeutic agents, serum sickness, angioneuroedema, and acute bronchial asthma. When a physician is confronted with a patient with such a disease, he must evaluate promptly the sum total of the medical situation. Proper diagnosis is the very essence of successful therapy. The therapeutic agent should be chosen and employed promptly. (We find it advisable in the beginning to administer sufficiently large doses of the agent chosen and taper off, if one can, so as not to overtreat the patient. When administered for short periods in properly selected patients, we need have little concern with toxic reactions and adverse physiological effects.) In each patient there may be many conditioning factors, some of which are heredity, age, previous disease, and nutritional state, all of which can exert their influence.

Fig. 1.—Structural formulas showing chemical relations of cortisone, hydrocortisone, prednisone, and prednisolone.

Hydrocortisone and prednisolone in the form of a salve or lotion are very effective in the treatment of certain skin disorders in the young, in the middle-aged, and in the aged. The hydrocortisone and prednisolone shown in figure 1 have a hydroxyl group on the 11-carbon and are a great deal more efficacious when applied locally than the two corresponding cortisone compounds. Likewise, cortisone and prednisone are not nearly as efficacious when injected into acutely swollen joints of patients with rheumatoid arthritis as are their analogues. (The ester of hydrocortisone most effective at this time and best suited is hydrocortisone tertiary-butylacetate.) Obviously then, the hydroxyl grouping on the 11-carbon is important in localized therapy. Hydrocortisone and prednisolone are incorporated in the ointment or salve in amounts of from 0.5% to 2.5%. They are painless, odorless, and practically invisible, and we have seen no sensitization to either compound. Pruritus and oozing from the skin are relieved promptly. Such treatment, of course, is suppressive, not curative. The skin of older persons is drier and rougher than that of younger persons. It has less turgor and elasticity and less fat. Drug eruptions are seen rather frequently in persons over 50 years of age, and itching may be the only evidence of drug intolerance. Circulatory, degenerative, and other diseases have an adverse effect on the skin. In the older person the allergic dermatoses tend to be more resistant to therapy than they are in the younger person. The most important single procedure in every case of allergic contact dermatitis is to find the causative agent and try to eradicate it. If the patient does not respond in a short time, a specialist certainly should be consulted.

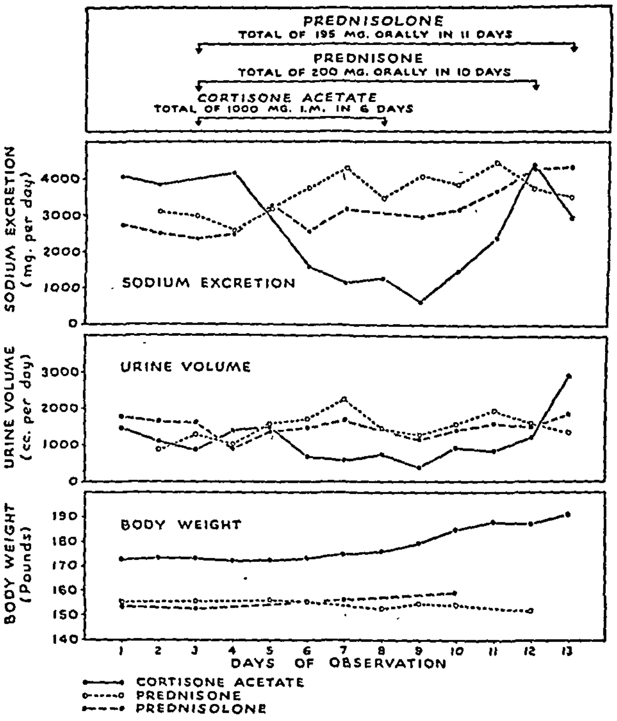

Fig. 2.—Comparison of effect of cortisone acetate, prednisone, and prednisolone on some factors of electrolyte metabolism in same patient.

EFFECTS ON BLOOD VASCULAR DISORDERS

Since we gained the impression that these new steroids sometimes tended to induce purpura and hemorrhages into the tissues, we decided to study the effects of large doses in various blood vascular disorders. Their dramatic effect on acute lupus erythematosus and certain cases of leukemia has been reported by a number of investigators, and we shall not say more. We wish to share our experience, however, in administering these materials in large amounts to patients with tropical sprue and lymphosarcoma, since we have not seen anything in the medical literature concerning their use in these diseases. Figure 3 shows the striking decrease in erythrocyte sedimentation rate and circulating eosinophils that occurred after the administration of prednisone in a patient with lymphosarcoma. The patient showed improvement promptly, the involved nodes decreased in size, and he had a great increase in sense of well-being. He developed no evidence of purpura or hemorrhages. Figure 4 shows the response of patients with typical cases of tropical sprue in relapse after the administration of prednisone and prednisolone. Not all cases of tropical sprue respond to these steroids, and certainly folic acid given orally and vitamin B_{12} given by injection are preferred methods of treatment. In fact, only patients with so-called refractory cases of sprue probably should have large doses of the adrenal steroids as a routine therapeutic trial. After the administration of adequate amounts of prednisone or prednisolone, the stools frequently change from liquid to solid just as they do after cortisone or hydrocortisone therapy. None of these patients developed hemorrhages or purpuric lesions in the skin, thus indicating that large doses may be beneficial, provided the time of treatment is not too protracted, without fear of blood vascular disorders.

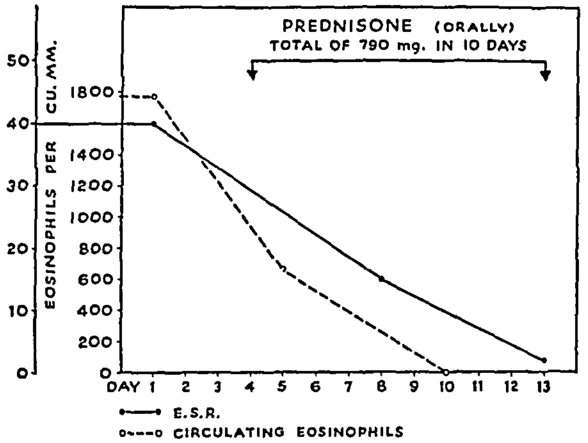

Fig. 3.—Effect of prednisone on erythrocyte sedimentation rate and circulating eosinophils in a patient with lymphosarcoma.

The fact that patients with such different syndromes as those mentioned above, and there are many others that we have not mentioned for lack of space, are benefited by the proper use of pituitary corticotropin and the steroids under consideration here supports a concept of their wide range as therapeutic agents. The amelioration of symptoms and disappearance of signs are clinical leads of great significance. One needs to know the effect on the pituitary and suprarenal glands of large doses of these steroids. Perhaps if this were known, we would know how to maintain normal functions of these glands. If we but knew enough, could we not augment function by giving proper nutrients? Is it not of the greatest significance that persons with adrenal cortical hypofunction or hypopituitary cachexia (Simmond's disease) do not have as an integral part of their syndrome arthritis, asthma, or any of these other conditions under consideration?

With this thought in mind, we will turn to a consideration of the medical problems, where there is more difference of opinion and a great deal of confusion. About one-third of the visits to doctors and clinics in the United States are made by patients who have arthritis and rheumatic diseases. These diseases are the nation's number one crippler. As a result of these diseases, some 5 million people are disabled, and each year about 300,000 become unemployed. There are many forms of rheumatic disorders—some 30 different clinical syndromes. Some of them, such as bursitis, myositis, scleroderma, lupus, and polyarteritis nodosa, are systemic only and may not involve the joints. Of all the rheumatic cripplers, rheumatoid arthritis is the worst. Its cause is unknown, and there is no specific cure for it. It strikes both young and old, but usually it appears between the ages of 20 and 50 years. Some 50% of those afflicted are disabled before they reach 45 years of age. The prognosis in many cases need not be poor if early and proper therapy is initiated. In older persons osteoarthritis is the most common form. These brief statements are the consensus of practically all physicians who have worked with arthritis and the rheumatic diseases.

In rheumatic disorders and other conditions, alterations in cellular metabolism may rapidly influence alimentation, absorption, and utilization of food elements. The long-term problem requires that we maintain proper caloric, nitrogen, vitamin, and electrolyte balances. Frequently supplemental vitamin therapy and assurance of an adequate protein intake are urgently needed. These two new steroids, like cortisone, hydrocortisone, and pituitary corticotropin, are appetite-stimulating. The increase in food intake shown in figure 5 is representative of the effect of either prednisone or prednisolone on the food intake of persons with collagen diseases. Frequently, when given enough time and an adequate diet, the patient

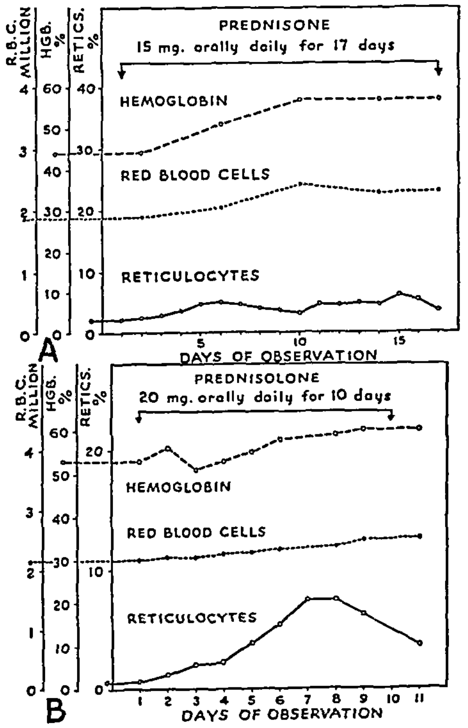

Fig. 4.—*A*, hemopoietic response of a patient with tropical sprue to prednisone. *B*, hemopoietic response of a patient with tropical sprue to prednisolone.

will restore his nutritional status toward the optimum. Supplementation of vitamins, minerals, and proteins is frequently required.

LIMITATIONS OF STEROID THERAPY

Before getting too far into specific studies and recommendations, we would like to stress, as we already have stressed in our recent article,[1] that the physician and the patient should recognize the limitations of steroid therapy; that is, these materials may give relief but they do not cure. They should guard against prolonged excessive therapy as much as possible. The physician should recognize the value of and exploit fully the use of salicylates. (They must be given as tolerated regularly, not just on occasion.) It is very important to evaluate the physical capacity of the patient and to encourage its maintenance through systematic activity, work, and/or exercises or other physiotherapy as tolerated and needed. Next and also very important, any added justifiable psychological boost should be given; that is, explain that in the course of events most cases eventually become quiescent; that in many patients activity decreases and becomes quiet; that in others there are varying degrees of activity, depending on unknown factors; that any therapy is aimed at tiding through periods of activity in hope of a period of remission; and that the better the general health can be maintained in the active periods, the better the condition in the quiescent period to follow.

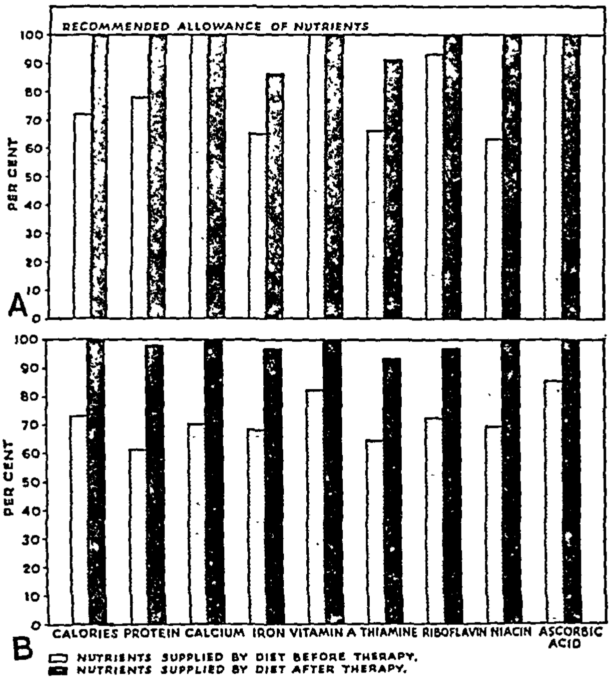

Fig. 5.—*A*, nutrients supplied by diet of patient with rheumatoid arthritis before and after treatment with prednisone. *B*, nutrients supplied by diet of patient with rheumatoid arthritis before and after treatment with prednisolone. Allowance of nutrients was recommended by the Council on Foods and Nutrition, National Research Council.

It has been obvious from the first that the steroids should always be used at a minimal dosage level. The symptoms of overdosage are well known. Acne, euphoria, abnormal appetite, frequency of urination, nausea and vomiting, headache, insomnia, leg cramps, hemorrhage, and moon face are a few of the important symptoms. Long-term treatment at a high dosage level has many hazards, and we frequently interrupt therapy to let the patient go as long an interval as possible without treatment. This has proved to be important, but we will not discuss it here as less severe cases can often be handled by a mixture of salicylates and these antiarthritic steroids. For many years we have used various forms of salicylates, and since 1948 we have been using various antiarthritic steroids and pituitary corticotropin. All of our studies have been concerned with preventing disabilities and avoiding overdosage. Each case is different, and if the physician is not resourceful, too often the body has to cope simultaneously with the disease and the remedy.

Since a considerable number of patients with chronic arthritis have been brought to us showing the stigmas of overdosage of pituitary corticotropin or the steroids, we have investigated and found that many of these patients had been undertreated, or in some instances not treated at all, with salicylates. Gradually we have shown [2] that the effect of salicylates and these newer therapeutic agents is additive and that combined therapy offers a more practical means of treating many arthritic patients. We have used many and various combinations of the salicylates and antirheumatic steroids, and we are of the opinion that there must be enough of the steroid to be definitely effective and enough of the salicylate to produce a strong additive effect so that less steroid will be required to produce the desired result.

EVALUATION OF STEROID AND SALICYLATE COMBINATIONS

The S. E. Massengill Company has sent us two formulations for evaluation. The first, Salcort, has been available for eight months, and, as far as we know, no doctor who has used it has found any evidence of water or sodium retention. It contains: cortisone acetate, 2.5 mg.; sodium salicylate, 325 mg.; aluminum hydroxide gel, dried, 130 mg.; calcium ascorbate, 65 mg.; and calcium carbonate, 65 mg. Each tablet of the second formulation contains: hydrocortisone acetate, 1 mg.; cortisone acetate, 2.5 mg.; potassium salicylate, 0.3 gm.; calcium carbonate, 60 mg.; calcium ascorbate, 60 mg.; calcium pantothenate, 5 mg.; and aluminum hydroxide gel, dried, 0.12 gm. We have found both of these products to be effective in relieving properly selected patients with rheumatoid arthritis and we have found no clinical evidence of water or sodium retention.[2] More recently the Schering Corporation has sent us a formulation, Sigmagen, that contains one of the new steroids with which we are concerned in this paper. Figure 6 shows graphically the relative proportion of the ingredients of each tablet. By weight the acetylsalicylic acid is 400 times that of prednisone. Prednisone has been shown by a number of investigators to be four to five times more potent per unit of weight than cortisone or hydrocortisone in relieving patients of the symptoms of arthritis.

---

1. Spies, T. D.; Stone, R. E., and Spies, H. A., Jr.: Metacortandracin and Delta 1 Dehydro-Hydrocortisone in Rheumatoid Arthritis, GP **12**: 73-78 (July) 1955.
2. Spies, T. D., and others: Nutrition and Disease, Postgrad. Med. **17**: 1-220 (March) 1955.

When we received the mixture of acetylsalicylic acid and prednisone, we decided to administer it to four patients whom we know well and in whom we know what type of response to expect. We considered that any combination of salicylates and these adrenal steroids, to be satisfactory, would have to produce a definite clinical improvement and decrease the erythrocyte sedimentation rate without significantly affecting the number of circulating eosinophils. The dosage and effect on the erythrocyte sedimentation rate of the four patients are shown in figure 7. In each patient there was a prompt clinical response beginning on the second day of therapy, and in none of the patients was there a significant decrease in circulating eosinophils.

Because it is important to avoid adrenal atrophy, we decided to do special studies of the effect of this mixture of acetylsalicylic acid and prednisone on the number of circulating eosinophils. We have a number of patients who have what we term chronic eosinophilia, whose circulating eosinophils decrease promptly and proportionately to the potency of the pituitary corticotropin injected. When the mixture of acetylsalicylic acid and prednisone was given to these patients in amounts up to three tablets four times a day, the circulating eosinophils of the peripheral blood did not decrease significantly. Yet, note what happened to a representative patient when other antirheumatic therapy was administered (fig. 8).

We then selected four patients who developed salicylism a few days after the administration of from 60 to 75 grains (4 to 5 gm.) of aspirin daily. We gave them the equivalent amount (in terms of aspirin) of the mixture of acetylsalicylic acid and prednisone. The patients all developed salicylism, but they still had a normal number of circulating eosinophils in their peripheral blood. Next we gave this mixture to some of the patients who had improved dramatically after the administration of suitable doses of prednisone or prednisolone.[1] The administration of these compounds was discontinued, and, when the patients were in relapse, they were given the mixture of acetylsalicylic acid and prednisone. Their response to this mixture began on the second day of therapy and was definite and good. It was not the dramatic, spectacular type of response that previously followed therapy with large doses of either prednisone or prednisolone. The patients were not as impressed with their improvement on the mixture of acetylsalicylic acid and prednisone as they were with that which followed prednisone or prednisolone alone in larger amounts. None of them had the euphoric type of response frequently observed on therapy with these compounds. Without exception, however, they all improved clinically as well as from the laboratory point of view. By giving the material as we did, that is, after meals and at night with food, none of the patients developed gastric distress, although three of them had developed it on former steroid therapy. From the results with these patients with uncomplicated rheumatoid arthritis, we decided to broaden our use of this mixture of acetylsalicylic acid and prednisone.

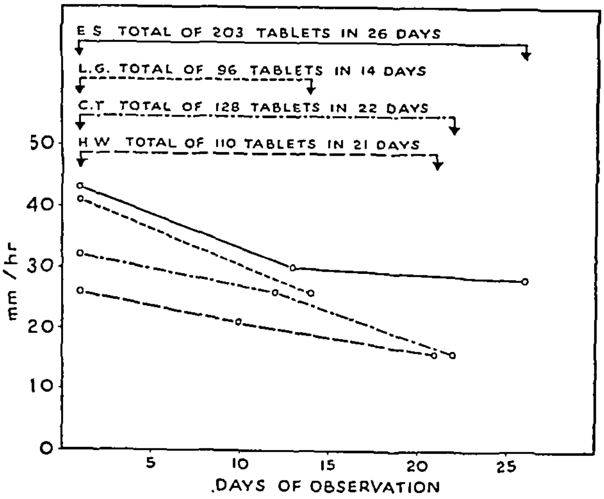

Fig. 7.—Effect of acetylsalicylic acid and prednisone on erythrocyte sedimentation rate of patients with rheumatoid arthritis.

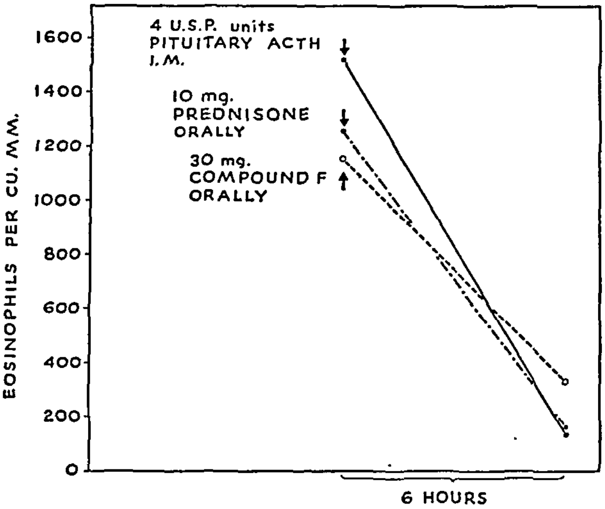

Fig. 8.—Relative decrease in circulating eosinophils in patient with chronic eosinophilia after administration of certain antirheumatic materials.

We then selected 19 patients with rheumatoid arthritis whose disability was sufficient to keep them from working but was not sufficient to keep them in a wheel chair or to keep them bedridden. After making baseline determinations on these patients, we selected from this group one patient with pernicious anemia in relapse and one with iron deficiency anemia in relapse and treated them with specific therapeutic agents, that is, vitamin B_{12} and ferrous sulfate, before giving them antirheumatic therapy. The case histories of these two patients and a third patient follow.

REPORT OF CASES

CASE 1.—A 64-year-old housewife was admitted complaining of weakness and aching of the left knee and of both feet and hands that had been present in varying degrees of severity for 25 years. Although she never was disabled, she did have to walk on crutches for several weeks soon after the onset of her illness. The pain and aching of her joints were constant and caused her considerable discomfort, especially in damp, cold weather. Many nights she could get little sleep. The pain "just seemed to use up all my energy so I have no desire to do anything, and I always feel weak and tired." She had had salicylates sporadically before she came to us, but she was never free of pain. In addition to her arthritis, which was obvious, she had pallor of the skin, nailbeds, and conjunctivas and some soreness of the tongue, which clinically suggested pernicious anemia. Laboratory findings confirmed this diagnosis. Her red blood cell count was 3,050,000 per cubic millimeter and hemoglobin 9.3 gm. per 100 cc. (60%). The bone marrow showed typical megaloblastic arrest. Repeated gastric analyses showed no free hydrochloric acid in the gastric juice even after histamine stimulation. Glucose tolerance curve was normal.

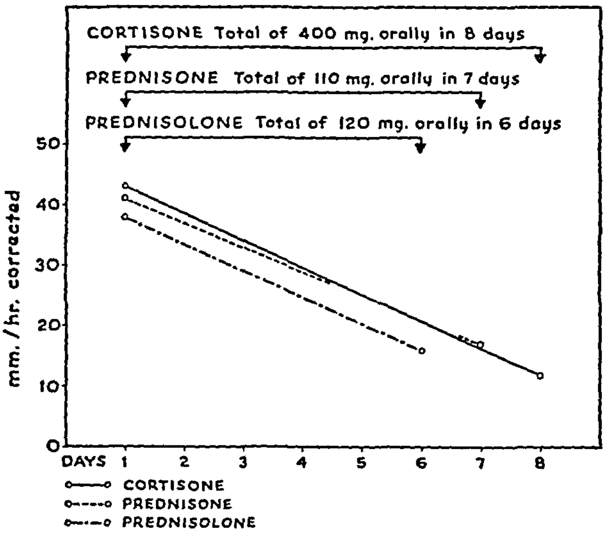

Fig. 9.—Relative decrease in corrected erythrocyte sedimentation rate with antirheumatic compounds in patient in case 2.

She was given 30 mcg. of vitamin B_{12}, which produced a typical reticulocytosis, followed by an increase in red blood cells and hemoglobin, relief of the soreness of her tongue, and disappearance of the pallor of her skin, nailbeds, and conjunctivas. While she felt much better in general, there was no relief of her arthritis, and two months later her blood values were down to the initial level. We gave her a potent intrinsic factor concentrate and 15 mcg. of vitamin B_{12} orally every day for 10 days. Again she responded as a typical pernicious anemia patient, but again the arthritis was not relieved, thus showing clearly that even though her anemia was corrected, she had not obtained satisfactory relief of her arthritis. It was obvious from the time the diagnosis of pernicious anemia was made that this patient would have to be treated with vitamin B_{12} for the rest of her life, and it will not be discussed further in this case summary.

She was given two tablets of the mixture shown in figure 6 30 minutes after each meal and two tablets before bedtime to be taken following food. After the first day of treatment, she had less aching of the joints and felt better than she had for a long time. For the first time in many months she slept all night. She stated that after therapy was initiated, she "just relaxed and went to sleep." The erythrocyte sedimentation rate slowly decreased from 22 mm. per hour to 15 mm. per hour (corrected) within a month. Circulating eosinophils did not decrease. She is now able to do all of her work and at the present time is being maintained with the mixture at the dosage level at which it was started. Later we may try to decrease it.

CASE 2.—A 41-year-old housewife was admitted three years ago complaining of arthritis, fatigue, and general weakness. Her illness began two years prior to this time with pain and swelling in the joints of her feet. Two months later her left wrist became involved. Gradually all her joints became involved. She lost her appetite, and, although she was never bedridden, she had to take aspirin every day to keep going. In addition to aspirin, she had had gold shots and physiotherapy. At the time we first saw her, she weighed 105 lb. (47.6 kg.) and appeared emaciated and anemic. Her arthritis was obviously active, and nearly all of her major joints were afflicted. Her hands and shoulders were almost useless, and her finger and wrist joints were so swollen and stiff that she could not open her hands. She was unable to raise her arms to comb her hair.

Her erythrocyte sedimentation rate was 44 mm. per hour (corrected). Her peripheral blood values were: red blood cells 3,750,000 per cubic millimeter and hemoglobin 9.7 gm. per 100 cc. (63%), and she appeared pale. Since we considered her to have an iron deficiency anemia, we gave her ferrous sulfate, 5 grains (0.3 gm.) three times a day. She continued to take aspirin when needed as she had previously. (In persons with arthritis and microcytic hypochromic anemia, the administration of ferrous sulfate frequently does not restore hemoglobin levels to normal, but there is usually significant improvement in the anemia.)

The arthritis did not decrease in activity or severity as measused by clinical or laboratory findings. After about two weeks her hemoglobin level began to increase and her general health began to improve. She gradually gained weight and strength; her fatigue decreased; and she became more energetic. At the end of two months she was a great deal better. She was much less weak and looked better, but her arthritis had not decreased in severity. We gave her cortisone, as seen in figure 9, and associated with the prompt decrease in erythrocyte sedimentation rate was a striking clinical response. She soon was able to do all her housework. Cortisone therapy was discontinued, and for several days she had a difficult time. Gradually she relapsed and we gave her prednisone, as shown in figure 9, with a similar striking change in sedimentation rate and clinical response. Again this therapy was discontinued, and again there was a similar relapse. We gave her prednisolone, as shown in figure 9, with a similar response. At this time she weighed 124 lb. (56.2 kg.). With the last two therapeutic agents it was difficult to find any circulating eosinophils in the blood. Once again she relapsed when taken off therapy, and her joints became stiff and painful. She was then given one tablet of the special steroid-salicylate mixture 30 minutes after meals and at bedtime after food. She obtained little relief after four days' treatment. The dosage was then increased to two tablets four times a day, and relief began in 24 hours after the increased dosage. Gradually all the pain left. She began to sleep well, and she feels that the relief from this therapy, although less spectacular, is as complete. She is eating well and is gaining weight without sodium retention; she weighs 132 lb. (59.9 kg.) and does all housework.

Most patients with moderately severe arthritis have definite evidence of some nutritive failure at times. The administration of the corticosteroids will bring up the nutritive status toward optimum. We feel, however, that patients respond much better and that it is better for them to receive heavy supplements of the water-soluble vitamins, protein, and minerals, especially iron and calcium. With heavy supplementation, the patient's convalescence frequently is shortened, and he may be able to return to work sooner than he otherwise would. Sixteen of the 17 remaining patients in the group had at some time during their illness taken aspirin. The following representative patient was selected because he never had had treatment of any kind.

Case 3.—A 64-year-old brickyard worker was admitted complaining of pain in the left leg and swelling, pain, and stiffness of the left knee. Thirty-five years previously he had rheumatism in his right leg that forced him to stay away from work for eight weeks. The present attack began eight months prior to his admission, with pain and swelling of his left knee. It was most painful when he was sitting or trying to sleep, and he could sleep only when his leg was in one certain position. As soon as he moved it, he awakened and usually could not get back to sleep. Often he felt so miserable when he came home from work that he went to bed without eating. He lost 12 lb. (5.4 kg.) in body weight. Despite his discomfort, he continued working until a week before his admission when he lost his job. He had taken no medicine but had rubbed his knee with liniment or alcohol. His pain was becoming increasingly worse. He came to the clinic with a friend whom we were treating for arthritis and asked to be treated because "I am hurting so bad and I've lost my job!"

Physical examination showed slight limitation of closure of his fingers. His left knee showed moderate increase in fluids. The knee was generally swollen and tender. Figure 10 shows the anterior aspect. He could flex his knee about 45 degrees. He could not straighten his leg. Erythrocyte sedimentation rate was 23 mm. per hour. He was given two tablets of prednisone and acetylsalicylic acid mixture 30 minutes after each meal and at bedtime after food. Relief of pain in his knee began the day after treatment was begun, and he had a more restful night than he had had in months. By the following day most of the swelling of his knee had subsided. By the fifth day the swelling had disappeared (figure 10). By the ninth day of therapy all the pain had disappeared. Slight soreness of the knee remains when he walks, but he feels "90 per cent more better".than he did before treatment. He sleeps well and eats well. His appetite is so good that "I could eat peanuts even though I haven't any teeth, and I can just sit down and sleep any time." He feels "good all over—just like getting up and going all the time." It is interesting that the pain in his knee was so prominent in his mind at the time of his admission that he was not aware that his other joints were stiff. When the pain and swelling of his knee decreased, he volunteered that all his joints were much less stiff and that he could move all of them with ease. After 10 days of therapy his erythrocyte sedimentation rate decreased to 13 mm. per hour. The circulating eosinophils in the peripheral blood decreased little. He has gained 6 lb. (2.7 kg.) in body weight and has returned to full-time work on his job.

This patient obviously would have obtained great relief from an injection of a proper antirheumatic compound into his knee joint, such as hydrocortisone or prednisolone, but he would not have had the general improvement that he had after treatment with the mixture of acetylsalicylic acid and prednisone, and he probably would have had to return within a few weeks for another injection. Each of the 19 patients showed definite, prompt, and continued clinical improvement after the administration of this mixture of acetylsalicylic acid and prednisone. The swelling of their joints decreased, as was shown by our x-rays, and the erythrocyte sedimentation rate decreased. The circulating eosinophils in the peripheral blood did not change regularly or significantly. We consider the response to this compound has answered our objectives mentioned previously.

We were contemplating how to obtain a mixture of prednisolone and acetylsalicylic acid to make studies similar to the above when the Upjohn Company sent to us for evaluation a suitable formulation under the name of Cordex. Each tablet of this formulation contained: 0.5 mg. delta-1-hydrocortisone and 300 mg. acetylsalicylic acid. We then selected 15 patients similar to those described above and followed the same procedures with essentially the same results, thus establishing that this compound also is a safe and effective therapeutic remedy. It is obvious that very severely affected patients will not obtain as much relief from any of these mixtures as might be desired, and they should be given large doses of corticotropin or the corticosteroids. The physician can decrease doses of corticotropin and corticosteroids oftentimes by administering a mixture of acetylsalicylic acid with either prednisone, prednisolone, hydrocortisone, or cortisone. The sooner he can make this change, the better the patient will be. None of these mixtures is recommended as the sole therapeutic agent of choice in persons with overwhelming rheumatic, arthritic, or collagen diseases.

COMMENT

Rheumatic diseases are by far the most common cause of chronic illness in our country. They kill relatively few of the millions they cripple. We have studied and are studying the effect of pituitary corticotropin, cortisone, hydrocortisone, prednisone, and prednisolone on the general clinical condition and the nutritional and metabolic processes of our patients. With the newer methods of treatment, the life of a patient with rheumatoid arthritis can take on an improved outlook. The treatment of such patients requires a knowledge of what is behind the physiological disturbance and judicious management of all pertinent factors.

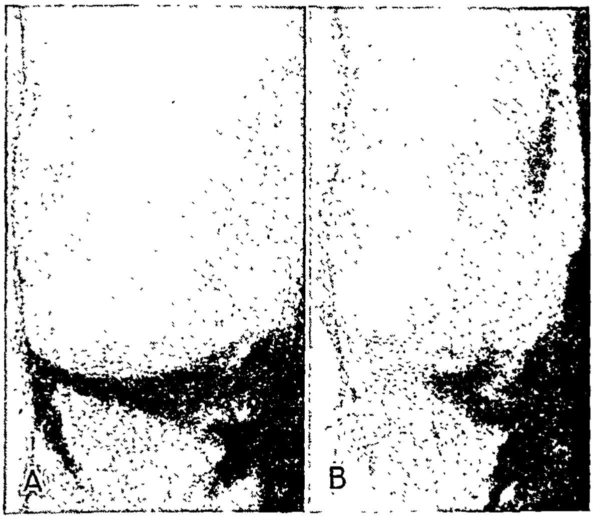

Fig. 10. Swelling of anterior aspect of knee of patient in case 3; *A*, at beginning of treatment and *B*, five days later.

The physician is guided by clinical symptoms of weakness, pain, appearance of the joints, appetite, changes in body weight, temperature, pulse, and laboratory findings. It must be emphasized over and over again that, although we have effective therapeutic agents, they are not in themselves replacement therapy. Many patients may lead an almost normal existence if one explains to them how to avoid undue stresses, strains, and fatigue, how to take suitable exercises, and how to manage their diets properly. Some of these patients are in danger of crises, and, if the patient is sufficiently stoic, the physician should warn him of impending dangers. He should make it clear to him that, although his illness is chronic, it may become seriously acute at any time. This can be explained to the patient in such a way that his heavy burden is made more understandable to him and more bearable. Much must be presented to the patient concerning the management of his illness—how to avoid overexertion, infections, marked changes in temperature, injuries, and improper diet. Dietary management is very important. Patients with rheumatoid arthritis tend to have some degree of malnutrition, and this should be corrected. The diet should be what is proper to maintain optimal weight; it should be high in protein, minerals, and vitamins, and the caloric intake should be adjusted to suit the individual needs of the patient. The physician should guard against prolonged excessive therapy. If the patient has had an overdosage of hormones, he should be taught the danger of overdosage and how to obtain as good results as possible without overdosage. In case of overdosage, the size of the dose should be decreased, of course, but it should not be done too abruptly.

The proper care of the patient includes an understanding of the altered physiological status of the patient and the use of a wide range of therapy. It must be highly individualized, but only at times of crises should the patient have constant therapy. During therapy the necessity of frequent observations cannot be overstressed. Although these new agents have been studied for a relatively short period of time, we have found that they fill a need and are not merely a duplication of therapeutic agents. Patients with heart disease, those with hypertension, and those who for reasons yet unknown tend to retain sodium when given cortisone, hydrocortisone, and pituitary corticotropin can be more easily and more fully treated with these new steroids. We believe that they have a special place in cases of rheumatism that can be controlled with salicylates and a small amount of the steroid. Once again we should emphasize that the benefits are suppressive only and that the smallest possible dosage is always preferred. With this mixture the patient can be treated in a more leisurely manner and can be better controlled. They usually feel better within 24 hours. Because of the smaller dose of steroid, they do not develop as much increased psychomotor activity, fat deposits, restlessness, and insomnia. There is an absolute necessity for long-term studies of the therapeutic agents used in arthritis.

The physician must relieve pain in his patients with arthritis, otherwise pain prevents adequate sleep and rest, adequate food intake, and sufficient exercise, all of which are important factors in recovery. Aspirin has had an uninterrupted popularity since it was first synthesized. It is commonly used at the rate of 15 tons a day in the United States. It is absorbed from the gastrointestinal tract, distributed through the body, and excreted in the urine. A large part of the salicylates in the blood is bound to plasma proteins. The tissue proteins bind the steroids in such a way that they properly act as a protein-steroid mixture, and, if they are used along with aspirin, temperature is lowered and painful tissues are relieved. These materials can be used to the point of tolerance, and, if possible, to complete elimination of the symptoms. They are rapidly absorbed, and gastrointestinal irritation is decreased and prevented if food is given with each dose of the material. Also, large amounts of fluid, at least 3,000 cc. a day, should be given. Many patients can be helped by suitable mixtures of aspirin and steroids, and nowadays, when hospitals are overcrowded, such mixtures are especially valuable in the treatment of arthritis.

SUMMARY AND CONCLUSIONS

Prednisone and prednisolone are important new therapeutic agents. They have in general the same clinical indications as pituitary corticotropin, cortisone, and hydrocortisone. They have the same contraindications, except that they do not tend to promote sodium and water retention. They are more active per unit of weight than the older corticosteroids, being four to five times as potent as orally given cortisone or hydrocortisone per unit of weight. We intensify all usual objective measures in care of patients and always use a minimal effective dose. The benefits to the patients are suppressive only, and the patients feel better in 24 hours. Objective criteria appear in one to four days. Control of the very severe forms of diseases is not always possible.

Throughout these studies we have tried to demonstrate by examples that the modern treatment of rheumatic diseases, especially rheumatoid arthritis, is a comprehensive and highly individualized program and not merely the administration of one or two antirheumatic agents. The many aspects of total, adequate care and medical management are far beyond the limits of this progress report. A completely specific antirheumatic agent has yet to be discovered. In all patients to whom we gave these two new corticosteroids, there was prompt and definite decrease of stiffness, pain, and tenderness, followed by a receding of swellings and effusions. The milder flexion deformities were corrected, and there was great increase in muscular coordination and range of motion of the affected joints. Likewise, the systemic symptoms and abnormal laboratory findings tended to return to normal. A proper mixture of salicylates and corticosteroids produces an effective antirheumatic agent in many patients, and the administration of such a mixture cuts down the danger of toxic reactions and restores the patients in many instances to employability. Of the three steroid-aspirin mixtures, only the Salcort contains ingredients designed to prevent or minimize the production of gastric acidity. These new corticosteroids should be used more widely so as to avoid the deformity, disability, nutritive failure, and all other things that may go with the risks of leaving the patient untreated.

Arthritis in the Elderly.—It is amazing how many elderly people will resign themselves to several years of hip, knee, or shoulder pain, believing that it is an inevitable accompaniment of ageing, rather than seek advice at an early stage when outpatient treatment is possible. Diagnosis is sometimes far from straightforward; beware the elderly patient who has signs and symptoms of osteoarthritis confined to one large joint, particularly the hip. Before we had a portable x-ray unit we treated these patients without x-ray examination but we never do so now. In 3 cases of unilateral arthritis, the cause was found to be an impacted fracture of the femoral neck which the patient could never recall sustaining; in 4 cases symptoms were due to secondary deposits in the upper femur or ilium; and in 3 cases we found Paget's disease of which there was no clinical evidence elsewhere. The response to mixed endocrine therapy in Paget's disease has been dramatic.—S. M. Vine, M.D., Clinical Pitfalls in the Elderly, *Lancet,* July 16, 1955.

RHEUMATIC FEVER—DIAGNOSIS, PROPHYLAXIS, AND THERAPY

Milton S. Saslaw, M.D., Miami, Fla.

Jones[1] divided the symptoms and signs of rheumatic fever into major and minor manifestations. Aware that other disease states may produce similar symptom complexes, he cautioned that his criteria be used only as a guide and that each sign and symptom be correlated with consideration of the patient as a whole. This is so important that it bears further emphasis. According to the American Heart Association,[2] to make a reasonably presumptive diagnosis of rheumatic fever, at least two of the major manifestations, or one of the major and two of the minor manifestations, must be present.

The major manifestations include arthritis, carditis, and chorea (table 1). Typically, arthritis begins in one joint and then travels to involve others; thus, the term migratory polyarthritis. The individual joint is red, hot, swollen, and painful. Fluid drawn from such a joint fails to yield any bacterial organisms. This symptom varies in severity and is uncommon in southern climates.

The second major manifestation, carditis, is probably present universally in rheumatic fever. Its evaluation depends on combined findings on physical examination and roentgenographic, fluoroscopic, and electrocardiographic examination. The development of a new murmur that changes its character is significant. In the early stages of rheumatic fever, the commonest murmur is a soft, apical systolic one. This, however, is difficult to interpret and often will defy final evaluation for many weeks or months. It should be remembered that such an abnormality may be an innocent murmur that was not previously recorded, or it may represent a temporary dilatation of the mitral valve ring, such as commonly occurs in any febrile illness. The observation of changing heart size on fluoroscopy or roentgenographic examination is, of course, indisputable evidence of cardiac involvement.

Most physicians have come to rely on the electrocardiogram as one of the most important tools in the evaluation of heart involvement. It is true that the P-R and Q-Tc intervals are prolonged in rheumatic fever,[3] but they are also lengthened by other toxic conditions. Moreover. a recent report by Engleman[4] and co-workers would seem to indicate that electrocardiographic changes should be carefully weighed, especially if they are the only signs indicative of cardiac involvement. In a follow-up study of 135 soldiers, four to eight years after their initial attacks of rheumatic fever, Engleman and his associates found that, of 34 who had had murmurs, with or without electrocardiographic changes during their Army illnesses, 30 had evidence of rheumatic heart disease at the end of the study. On the other hand, of 35 who had had electrocardiographic disturbances as the sole evidence of rheumatic infection, only one was found to have heart disease on follow-up.

The third manifestation of rheumatic fever is ordinary chorea. This has been linked to rheumatic fever because of its frequent coexistence with other symptoms of the disease and because rheumatic heart disease follows more cases of chorea than might be anticipated. Today, the relationship of chorea to rheumatic fever is open to question for a number of reasons. Although approximately 75% of those with rheumatic fever develop heart lesions in the course of 10 years, only 5% of those with "pure" chorea, that, is chorea as the only symptom of rheumatic fever, ultimately develop heart disease.[5] In "pure" chorea, females vastly predominate,[6] but this is not so in rhematic fever as a whole. Furthermore, certain laboratory data are different in "pure" chorea. Unlike the situation in other forms of rheumatic fever, in "pure" chorea there is no increase in hexosamine,[7] serum levels of nonspecific hyaluronidase inhibitor,[8] and serum mucoproteins[9]; there is no bone marrow plasmacytosis[10]; and C-reactive protein is absent.[11] Rheumatic fever does not follow chorea unless there is an increase in the erythrocyte sedimentation rate, but elevations in the erythrocyte sedimentation rate in "pure" chorea may well be due to other hidden areas of involvement, notably unrecognized carditis. There is another indication that "pure" chorea may be a different entity from rheumatic fever. Streitfeld and I[12] have observed that patients with "pure" chorea give different responses from patients with active rheumatic fever to a skin test that we are developing for the determination of rheumatic activity. This test will be discussed in greater detail.

The minor manifestations of rheumatic disease (table 1) include fever, failure to gain weight, epistaxis, various skin lesions (erythema nodosum, erythema multi-

forme, and subcutaneous nodules) and lassitude, as well as a number of changes in the blood and serum, such as elevated sedimentation rate, leukocytosis, anemia, and alterations in certain antibody responses. Electrocardiographic changes have already been discussed.

The serologic changes in rheumatic fever are valuable diagnostic aids. Two of the most frequently used tests are antistreptolysin-O and C-reactive protein determinations. The former specifically measures the antibody response to oxygen-labile streptocolysin, one of the extracellular antigens produced by group A beta hemolytic streptococci. It is therefore an index to infections with this group of organisms that are believed to be etiologically related to rheumatic fever. This disease has been reported [13] to follow approximately 3% of all group A beta hemolytic streptococcic infections. The C-reactive protein test, on the other hand, is nonspecific, being positive in many disease conditions. It therefore can be used only as a guide in following activity in rheumatic disease after the diagnosis is already established, in the same way as the sedimentation rate is used.

TABLE 1.—*Manifestations of Rheumatic Fever*

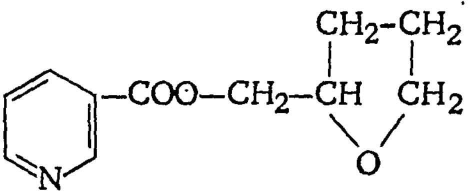
Major
Migrating polyarthritis
Ordinary chorea
Carditis

Clinical
Fever
Abdominal pain
Erythema marginatum or multiforme
Precordial pain
Subcutaneous nodules
Purpura
Epistaxis
Pulmonary involvement
Muscle or joint pains
Anorexia
Easy fatigability
Retardation of growth

Laboratory
Electrocardiographic changes
  P-R prolongation
  Q-Tc prolongation
  Sinus tachycardia
  Other rhythm changes
Microcytic anemia
Leukocytosis
Increased sedimentation rate
Serologic abnormalities
  Elevated antistreptolysin-O titer
  Elevated antihyaluronidase titer
  Increased antistreptokinase
  Presence of C-reactive protein

Antistreptolysin-O titers vary markedly according to the age and geographic origin of the individual. Rantz [14] noted a mean titer of 1:238 in children 5 to 12 years of age in the San Francisco area. This is in contrast to a mean titer of only 1:100, which Streitfeld and I [15] found in a study of 996 serums taken from Miami school children 6 to 8 years old. In general, it has been stated that rheumatic fever is attended by a higher, more persistent elevation in antistreptolysin-O titer averages than uncomplicated streptococcic disease. The wide variations observed in antistreptolysin-O titers within any single population make the interpretation of a single sample from any one individual at any one time difficult and of dubious value. Only serial studies, taken at three to four-week intervals, will permit adequate evaluation. Furthermore, in our own titration studies in Miami we have observed rises in antistreptolysin-O titer in children harboring group C and group G organisms in their throats similar to those in children from whose throats group A beta hemolytic streptococci were recovered. Group C and group G beta hemolytic streptococci, according to our present concepts, are not related to rheumatic fever.

Although Jones' criteria, together with laboratory tests and serologic studies, enable us to diagnose rheumatic fever with reasonable accuracy, I am sure that many physicians have at some time hoped for a single specific test, especially in atypical cases, where the evaluation of rheumatic activity is difficult.



Structural formula of Trafuril.

For the past year and a half at the National Children's Cardiac Hospital, Streitfeld and I have been working on a test for rheumatic activity, which I mentioned earlier. We have found [12] that when a 5% ointment of Trafuril (the tetrahydrofurfuryl ester of nicotinic acid) is applied to the skin, normal subjects and patients with inactive rheumatic disease and congenital heart disease develop hyperemia, with or without edema, at the site of application. This has been termed a typical (normal) reaction. In contrast, patients with rheumatic activity give a nontypical response characterized by failure of the skin to redden or by blanching. Thus far, about 1,200 tests have been performed by 37 investigators working independently throughout the country. Preliminary results seem to indicate that skin testing with Trafuril may be of value in distinguishing active from inactive cases of rheumatic fever. A typical hyperemic reaction was observed in 95% of our normal subjects and in 97% of the patients without active rheumatic disease, as against a nontypical response in 86% of the active cases (table 2).

TABLE 2.—*Responses to Trafuril*

Group, by Diagnosis	No. of Cases	Typical		Atypical		Doubtful	
		No.	%	No.	%	No.	%
1. Controls (healthy normal subjects)	271	258	95.2	9	3.3	4	1.5
2. Congenital heart disease	57	52	91.2	5	8.8	..	...
3. Rheumatic fever, active	114	15	13.2	98	86.0	1	0.8
4. Rheumatic fever, inactive	356	346	97.2	6	1.7	4	1.1
5. Rheumatic activity, suppressed	22	15	....	7	...	..	...
6. Questionable rheumatic activity	39	23	....	12	...	4	...

Studies are in progress to determine the specificity of this test. There is some indication at the present time that the nontypical response noted in patients with active rheumatic fever may be due to streptococcic infection rather than to rheumatic fever per se. The underlying mechanism of the test also is under investigation.

PROPHYLAXIS

What can be done at the present time to prevent rheumatic fever? There is no known direct preventive measure. Prophylaxis of the disease is aimed at preventing infections with group A beta hemolytic streptococci, which precede initial or recurrent attacks of rheumatic fever. The recommendations of the American Heart Association are familiar: that sulfonamides or penicillin be administered daily for at least five years or until the age of 18 (whichever is later) to all persons who have had one or more attacks of rheumatic fever. It is believed that in this way streptococcic infections will be prevented, and thus also rheumatic attacks. In our era of rapid development of countless new drugs, many of which have apparent bacteriostatic or bactericidal effects on the beta hemolytic streptococci, it is difficult to decide which agent is most effective in eradicating streptococci from the throats of potential victims of rheumatic fever. For this reason, present policies, as advocated by the American Heart Association, may be regarded as interim policies and undoubtedly will be modified from time to time.

[15] Streitfeld, M. M.; Saslaw, M. S., and Doff, S. D.: Group A Beta Hemolytic Streptococci and Rheumatic Fever in Miami, Fla.: Bacteriologic and Serologic Studies from October, 1953 through May, 1954, to be published.

In the light of our present knowledge, let us consider who should receive prophylaxis. Ideally, everyone who is susceptible to rheumatic fever should be protected. However, rheumatic fever may attack anyone at any age. Furthermore, group A beta hemolytic streptococci, the *sine qua non* of rheumatic disease, is not at all a rare organism. In a survey that Streitfeld and I have been conducting in healthy first and second grade school children in Miami, we found[15] that, of 351 whose throats were swabbed at monthly intervals from October, 1953, through May, 1954, 37.9% had group A beta hemolytic streptococci recovered from their throats at least once. When corrections are made for absentees, for the four-month school vacation period not included in the study, and for the technical possibility of failure to recover streptococci, it is reasonable to assume that about half of the children 6 to 8 years old in Miami, Fla., harbor these organisms in their throats at least once a year. Furthermore, as indicated previously, those children from whose throats the organisms were recovered had significantly higher antistreptolysin-O titers than those from whom no such organisms were cultured. This indicates that the streptococci recovered evoked a systemic reaction and thus definitely exerted an effect on these subjects.

Therefore, it is obvious that for a program of prophylaxis to be maximally effective, all children, at least, should receive preventive medication. As children constitute about 15% of the total population, this would mean that over 10 million children in the United States would have to receive antibiotics. Furthermore, as the protective action of antibiotics against streptococcic infection is not effective after medication has been stopped for a two-week period, prophylaxis would have to be administered on a relatively permanent basis. Obviously, such widespread prolonged administration of drugs is not feasible.

A more reasonable approach therefore has been to give medication to children who have already demonstrated a susceptibility to rheumatic disease by having had an episode of this illness. This explains why, at the present time, the American Heart Association recommends that every child who has had one or more attacks of rheumatic fever, with or without heart disease, should be placed on a program of continuous protection.

How long should preventive measures be used? As the number of initial and recurrent attacks of rheumatic fever falls sharply at adolescence, and as over 90% of recurrences occur within a five-year period following the last previous episode of the disease, the American Heart Association states that all children with a history of rheumatic fever should be constantly maintained with medication until the age of 18 years. In those individuals who suffer an attack of the disease after the age of 13 years, therapy with such drugs should be continued for a minimum period of five years. Some workers even extend their recommendations for prophylaxis in rheumatic subjects to lifetime use of appropriate medication. Therapy should be started two weeks after a streptococcic infection, or when a rheumatic patient is first seen.

What drugs and what doses are to be used? The sulfonamides and penicillin provide the most effective agents at this time. The sulfonamide of choice is sulfadiazine, which has as its chief advantage over penicillin its lower cost and the fact that it can be used in those patients who have developed sensitivity to the antibiotic. Sulfadiazine is given in 0.5 to 1.0 gm. doses, depending on the weight of the patient. In administering sulfadiazine, it should be remembered that since this drug is bacteriostatic and not bactericidal in its action, it has no effect in eradicating an acute streptococcic infection once it has been established, but it can be used very effectively to prevent reinfection. Also, it should be borne in mind that resistant strains of group A beta hemolytic streptococci have been known to develop with the prolonged use of sulfadiazine, and some children are sensitive to this agent.

Penicillin is far more costly than sulfadiazine. Sensitivity reactions to penicillin have been reported in from 3 to 15% of those to whom it has been administered. On the other hand, no resistant strains of group A beta hemolytic streptococci have been reported when penicillin is given. Furthermore, penicillin is bactericidal and will eliminate whatever infection exists, as well as prevent new organisms from causing disease. The antibiotic can be given by mouth in 300,000 unit tablets twice a day, a half to one hour before meals or at bedtime. In many states, penicillin tablets are provided by the state health agencies, thus making it possible for indigent children to obtain suitable medication that they could not otherwise afford.

A new form of penicillin has recently been studied by Stollerman and Rusoff.[16] It is long-acting benzathine penicillin G, the administration of which is by intramuscular injection. The penicillin blood level maintained by this form of the antibiotic is high enough to prevent streptococcic infection for a period of one month. Thus, a single injection of 1,200,000 units in 2 cc. of vehicle may be given every 28 days for protection. This method of prophylaxis has some very real advantages. In the first place, the physician knows that his patient is taking his medication properly. In no form of oral medication can the doctor be certain that the patient is taking a drug regularly. Prophylaxis with benzathine penicillin removes the necessity for daily medication.

---

16. Stollerman, G. H., and Rusoff, J. H.: Prophylaxis Against Group A Streptococcal Infections in Rheumatic Fever Patients: Use of New Repository Penicillin Preparation, J. A. M. A. 150: 1571 (Dec. 20) 1952.

The total cost is about $30 per year per patient, a small fraction of the cost of daily medication. Finally, comparatively few penicillin reactions have been observed with benzathine penicillin. On the other hand, one deterrent to its use is the severe pain produced at the site of injection for a day or two thereafter. Until they are replaced by more effective drugs, sulfadiazine and penicillin are today the most effective prophylactics against rheumatic fever.

THERAPY

The treatment of rheumatic fever may be broken down into four stages: first, treatment of acute streptococcic infections; second, treatment of the active phase of the disease; third, treatment of the patient during convalescence; and fourth, treatment of the patient in the late stages of the disease when cardiac involvement occurs.

Active streptococcic infection should be diagnosed as soon as possible and eradicated in every patient at once. As sulfonamides are bacteriostatic and not bactericidal, they should not be used therapeutically. On the other hand, penicillin is most effective and should be given early and in therapeutic doses orally or by injection. The oral dosage is 200,000 units four times daily for children, or 300,000 units four times daily for adults, for five days, followed by three doses daily for an additional five days. The dosage by injection is 300,000 units of procaine penicillin with aluminum monostearate in oil intramuscularly every three days for three doses for children and 600,000 units for each of three injections for adults.

Broad-spectrum antibiotics, such as oxytetracycline (Terramycin), chlortetracycline (Aureomycin) and tetracycline may prove equally effective in eradicating streptococcic infections in rheumatic patients. Preliminary studies in our laboratory indicate that oxytetracycline, tetracycline, erythromycin, and chlortetracycline exert the greatest effect on beta hemolytic streptococci in vitro. The active phase of rheumatic fever requires bed rest, a highly nutritious diet, and other supportive agents generally in use in infectious diseases. There is no therapeutic measure that can be considered curative. The time-honored salicylates are still the drugs of choice, and the two easiest forms to administer are aspirin and sodium salicylate. These drugs can be given in large doses as tolerated—up to 8 gm. per day for a 12-year-old child of average weight. It may be necessary to add sodium bicarbonate to lessen gastric disturbances. As *p*-aminobenzoic acid tends to increase the salicylate concentration in the blood when the two drugs are given together, the use of such a combined drug may result in greater efficacy than when the salicylates are used alone.

The use of cortisone and corticotropin (ACTH) must be discussed. The best recent report on this subject is that of Massell.[17] It would appear that the final evaluation of these medicaments in rheumatic fever is yet to be made. There are those who believe that the drugs shorten the period of acute illness, lessen its severity, and decrease the likelihood of cardiac complications. There is little doubt that the symptoms of the acute process are suppressed. It is still too soon to evaluate the effect of these drugs on cardiac involvement. If cortisone and corticotropin were completely innocuous, there would be little reason for withholding them, but they are capable of producing severe reactions in the dosages necessary to achieve desired therapeutic effects. Hence the utmost caution should be exercised in their administration.

The management of congestive heart failure during the acute phase of rheumatic fever poses a serious problem. Should digitalis be given? Yes, and in adequate dosage, for it has recently been shown that many failures of digitalis therapy in children were due to the fact that children require a larger proportionate dosage than adults. The management of the convalescent stage of rheumatic fever is characterized by watchful waiting. The physician must be sure that there is no longer any evidence of activity. There must be no fever, no joint symptoms, no chorea, and no skin lesions; the pulse must be normal; and the various laboratory findings should return to normal values. Ambulation is begun as therapy is withdrawn. Some men recommend the continuation of salicylates for a minimum of six months, even after ambulation has been achieved. Getting the patient up and around must be a slow, gradual, and careful procedure. At this time, perhaps more than any other, it is essential to keep a close vigil in search for the minor changes that may indicate recrudescence of the disease.

It is my belief that institutional care, particularly in Miami, Fla., is extremely beneficial. There are fewer recurrences and less severe complications. Usually the period spent in bed is markedly less than that which might be expected in temperate areas; instead of months, it is usually measured in weeks. Instead of large doses of aspirin, we have used only moderate doses (usually not over 60 grains [2 gm.] daily).

Institutional care has the advantage that the children can be watched carefully over a long period of time and be provided with the necessary medical, nursing, educational, and psychological services especially geared to their individual condition and emotional make-up, so that they can return to their homes and become useful, contributing members of society.

Therapy in the late stages of rheumatic fever concerns itself with management of the cardiac and other complications of the disease. Congestive heart failure and subacute bacterial endocarditis occur frequently and are treated in the same way as when they occur in other forms of heart disease. The various forms of valvular involvement do not require active therapy until symptoms and signs appear. Here, the recognition of mitral stenosis, pure and uncomplicated, is of utmost importance, for this lesion best responds to surgical intervention. Cardiac catheterization can be most helpful in identifying those patients with rheumatic heart disease that can be benefited by surgery. Attempts also have been made to repair other valvular lesions. Undoubtedly, as new techniques are developed there will be a brighter future for many more rheumatic heart disease victims.

CONGENITAL RENAL POLYCYSTIC DISEASE

A CLINICAL AND THERAPEUTIC STUDY OF THREE HUNDRED SIXTY-SIX CASES

Howard B. Simon, M.D.
and
Gershom J. Thompson, M.D., Rochester, Minn.

Much prognostic pessimism has been associated with polycystic disease of the kidney. When the variability of the clinical manifestations and course of this not uncommon clinical entity is considered, the pessimistic prognosis is oftentimes unwarranted and unjust to the patient. The present study was undertaken to elaborate further on the various aspects and manifestations of the disease that, when properly evaluated, permit the physician to outline treatment more accurately and prognosticate in a given case.

PATHOGENESIS

The pathogenesis of polycystic disease is not completely understood. The various theories of etiology that have been proposed were summarized by Rall and Odel [1] under the categories of metabolic, inflammatory, neoplastic, and developmental defects. Since Rall and Odel covered this aspect of the condition, we will mention only two recent contributions. Experimentally, Bagg [2] has been the only one successful in producing a true polycystic kidney. He treated the abdomens of mice with unfiltered roentgen rays. He concluded that the tendency to congenital renal anomalies is inherited as a Mendelian recessive trait. Of interest in this regard is the fact that in two of our cases polycystic changes were demonstrable in horseshoe kidneys, an association previously reported by Botez.[3]

Several authors have expressed the belief that polycystic disease in the infant is distinct from the adult disease, differing pathogenetically as well as clinically. Lambert [4] reconstructed two infant and five adult polycystic kidneys and found that in the infant the majority of cysts were distended nephrons or enlarged portions of nephrons that were separated from their excretory tubules, thus forming a closed system not communicating with the pelvis. In the adult, on the other hand, some of the cysts were similar to the infant type, but many, tubular in origin, were connected to excretory tubules and the renal pelvis and still retained some functional ability. For this reason he expressed the opinion that patients with the adult type were able to live beyond infancy.

PRESENT SERIES

Our study consisted of 366 cases of polycystic disease of the kidneys seen during the years 1925 to 1944 inclusive, at the Mayo Clinic, with autopsy in 35 cases. These represent a clinical incidence of 1:2,438, and an autopsy incidence of 1:323 for the years under consideration. Cases in which the diagnosis seemed equivocal were excluded from our series. Clinical records including data obtained at the time of later visits were examined in all cases, and follow-up questionnaires were sent to all patients pertaining to the data with which this report concerns itself. We were thus able to secure reasonably complete information in the majority of cases despite the time interval since many of the patients were last seen or heard from.

AGE AND SEX

The age at time of the first examination at the clinic and sex distribution are outlined in table 1. Of the nine patients on whom the diagnosis was made during the first decade of life, six were less than 3 months old and the others were aged 1, 3, and 4 years respectively. The diagnosis was confirmed by autopsy or at surgical exploration in all but one of these cases, and in that case the diagnosis seemed certain on the basis of clinical and pyelographic evidence. As pointed out by Campbell,[5] the prognosis when the condition is diagnosed in infancy is poor; the majority of such patients die within three months after the onset of symptoms. This was true in all but one case in our series. Of the 13 patients whose condition was initially diagnosed between the ages of 66 and 74 years, 9 were then asymptomatic. The diagnosis was confirmed at autopsy or operation in eight of these patients, the remainder being verified on the basis of urographic and clinical data (fig. 1).

Bell,[6] in his review of autopsy series reported in the literature, found 59 patients less than 20 years of age, plus 28 stillborn infants, and 6 patients more than 70 years of age, to which he added autopsies on 22 persons less than 1 year of age, 14 stillborn infants, and 17 persons more than 70 years of age, 3 of whom were in their 10th decade. In our series 80% of the patients were in the fourth to sixth decades of life at the time of diagnosis, with the largest number appearing during the fifth decade. The average age was 44 years. The slight preponderance of males (55.5%) in our series is probably insignificant, as most writers agree that no sex predilection exists.

FAMILY HISTORY

A definite family history of polycystic disease was obtained in 66 cases, with a probably positive family history in 85 additional cases. For example, the father

and brother of one patient died of "kidney trouble" during the sixth decade of life, and seven siblings and five members of the mother's family of another patient had "kidney trouble" and high blood pressure. In 55 cases there was no family history of renal disease. In the remaining 160 cases a familial history of renal disease was not mentioned in the clinical history. It is assumed that the family history was probably negative in this respect in these cases.

As previously mentioned, Bagg [2] stated that congenital renal anomalies were inherited as a Mendelian recessive trait, and the literature contains numerous accounts of the familial tendency in polycystic disease. Crawford [7] cited one family in which the disease was traced through five generations with 17 of 40 members so afflicted, 7 of 9 siblings in the fifth generation having polycystic disease. In other series, 9 of 27 members in four generations [8] and 12 of 24 members of two generations in a family in which the disease could be traced back four generations [9] were reported. In one of our cases, the disease had manifested itself in three generations. The patient's sister had polycystic disease, her mother and four of her mother's five siblings had all died in their fifth decade of life of kidney trouble, and her 21-year-old son also had polycystic disease. She was unable to provide information concerning her maternal grandparents.

TABLE 1.—*Age and Sex Distribution of Patients with Polycystic Renal Disease*

Age, Yr.	Patients	%
0-9	9	2.5
10-19	4	1.1
20-29	32	8.7
30-39	82	22.4
40-49	125	34.2
50-59	82	22.4
60-69	25	6.8
70-79	7	1.9
Total	366	100.0
Mean	44.0 yr.	
Male	203	55.5
Female	163	44.5

One patient, not included in the present series because he was seen initially in 1949, nevertheless warrants description because his identical twin brother had succumbed to polycystic disease within two years of the similar death of our patient. The parallelism in their clinical courses was remarkable.

REPORT OF A CASE

A 36-year-old white man was seen at the Mayo Clinic in July, 1949, because of loss of weight, occasional nausea, and anorexia. Five years previously he had had one episode of colic in the left flank and gross hematuria, lasting two to three hours. His twin brother had several similar episodes of hematuria in 1942 and 1943, at which time the diagnosis of polycystic disease had been made elsewhere. He had high blood pressure, and finally, in 1948, at the age of 35 years, had succumbed after a "stroke." After the diagnosis of polycystic disease in his brother's case, urographic studies done elsewhere on our patient had disclosed similar polycystic changes. Since then, hypertension had increased in severity.

On admission blood pressure was 164 mm. Hg systolic and 120 mm. diastolic. Kidneys were enlarged bilaterally to the size of a grapefruit. Funduscopy revealed marked narrowing of his retinal arterioles with focal constrictions and slight hypertensive sclerosis. The value for blood urea was 72 mg. per 100 cc. and for hemoglobin 11.2 gm. per 100 cc., with an erythrocyte count of 3,300,000 cells per cubic centimeter. Urinalysis revealed albuminuria, erythrocyturia, and pyuria of grade 1 based on a grading of 1 to 4. The specific gravity of urine was 1.007. Excretory urography demonstrated bilateral delay and decreased function with diagnostic changes of polycystic disease. The patient was treated with transfusion and a high intake of fluid and discharged to go home. In November, 1950, he suddenly suffered from a vise-like substernal pain and was admitted to his local hospital in shock with a diagnosis of acute myocardial infarction. He recovered somewhat, but seven days later suddenly died.

At autopsy a dissecting aneurysm of the ascending thoracic and abdominal aorta with intimal tear at the root of the aorta and rupture into the pericardial sac with hemopericardium were found. The right polycystic kidney weighed 1,575 gm. and the left 1,275 gm.; almost all of the renal parenchyma had been destroyed. Myocardial hypertrophy and renal and cerebral arteriosclerotic changes, grade 2, were also noted.

Reason,[10] in 1933, reported the cases of identical twin sisters who had died at ages 43 and 51 years of polycystic disease. He also cited several other reports of polycystic disease occurring in twins.

CLINICAL DATA

Symptoms.—The clinical picture of polycystic renal disease is variable and depends on the stage when the patient presents himself for examination. The onset may be insidious, and the patient may be totally unaware of his affliction until a physician, during a routine checkup, discovers a renal tumor, hypertension, pyuria, or microhematuria and establishes the diagnosis. In some cases the kidneys are almost completely destroyed before symptoms are noted. In our series 133 patients had no symptoms referable to the polycystic disease at the time of initial diagnosis. In other patients symptoms either developed slowly or appeared suddenly and were severe with progressive renal failure and a rapid downhill course. The more commonly noted symptoms will be considered.

Pain was described as a dull or nagging ache by 130 patients. It usually was unilateral and probably due to the excessive weight of the kidney producing tension on the renal pedicle, increased intracystic pressure, intracystic hemorrhage, or mechanical pressure of the cysts on adjacent organs. Occasionally, pain was noted only during episodes of pyelonephritis. In 33 patients the pain was colicky in type, unilateral, and almost always associated with either gross hematuria and the passage of clots or with concomitant renal calculi. Thus, 163 (44.5%) of our patients complained of pain when initially examined. Of 75 patients in whom pain was not an initial complaint and in whom follow-up information concerning its presence or absence was available, 21 later had typical pain. Pain, then, usually occurs at some time in the majority of cases of polycystic disease, and it is by far the commonest associated symptom.

Gross hematuria, noted in 115 of our patients, was usually episodic, of brief duration, and precipitated in most instances by trauma or excessive physical exertion.

Associated renal colic, due to the passage of clots as previously mentioned, is often mistakenly diagnosed as nephrolithiasis until further investigation reveals the correct diagnosis. Of 94 patients questioned concerning the eventual appearance of gross hematuria, 23 (24.4%) reported affirmatively. Thus, it can be assumed that about one-half of the patients will have gross hematuria at some time during the course of their illness.

Seventy-seven patients (21.0%) gave a history of symptoms of urinary infection, such as frequency, dysuria, burning, chills, and fever; the diagnosis was confirmed either elsewhere previously or at the time of admission. Follow-up of symptoms in 77 patients showed that 13 later had symptoms of urinary infection, so that approximately a third of patients at some time suffered from urinary infection. With present-day chemotherapeutic and antibiotic agents this incidence will undoubtedly be lessened.

* Based on traced patients. Inquiry as of Jan. 1, 1954.
† Patients with microhematuria and pyuria are excluded.
‡ 39 patients with microhematuria only and 115 with gross hematuria are included.
§ 93 patients with asymptomatic pyuria and 77 with symptoms of urinary infection are included.

The cases in which neither gross hematuria nor symptoms of urinary infection were evident, but in which examination of the urine revealed the presence of microhematuria or of pyuria with urinary infection, have not been included here. These cases will be considered later.

Gastrointestinal symptoms, such as nausea, vomiting, and anorexia, were reported by 28 patients (7.7%). Renal insufficiency and uremia, with loss of weight, weakness, easy fatigability, edema, and other signs of renal failure were invariably associated. These symptoms were relatively terminal in the disease, and their rarity in our series was primarily the result of diagnosis before their occurrence. Follow-up data were inadequate concerning the occurrence of these symptoms since they closely preceded the death of the patient and later correspondence usually revealed only the date of death without reference to the terminal clinical course.

Signs.—The frequent association of hypertension with polycystic disease was first pointed out by Braasch [11] in 1916. For the present discussion we arbitrarily classified the blood pressure of those patients whose systolic pressure exceeded 160 mm. Hg or the diastolic exceeded 90 mm. as moderately elevated, and that of patients whose blood pressure exceeded 200 mm. systolic and 110 mm. diastolic as severely elevated. The distribution of our patients accordingly is shown in table 2.

Fifty-five per cent of patients were found to be hypertensive, and 35 patients (50%) initially normotensive had elevated blood pressure at the time of reexaminations. It would appear, therefore, as if at least four-fifths of patients become hypertensive during the course of the disease. Palpable enlargement of the kidneys was demonstrated bilaterally in 187 patients (51.1%) and unilaterally in 98 patients (26.8%). Three of these had only a solitary kidney, the other having been surgically removed previously. Of the 81 patients in whom no enlargement was palpable initially, 24 later returned for examination, at which time 12 (50%) had palpable enlargement, either unilaterally or bilaterally. Thus, the vast majority of patients had palpable enlargement of at least one, and usually of both kidneys.

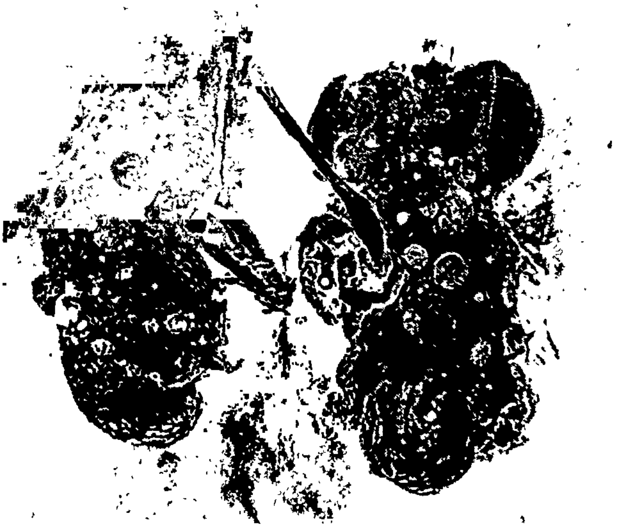

Fig. 1.—Polycystic kidneys from a 71-year-old man who died in renal insufficiency with uremia.

Laboratory Studies.—Albuminuria was found in the majority of patients and a specific gravity of urine of less than 1.010 was frequently noted. Microhematuria was found in 109 patients, of whom 39 had never experienced gross hematuria (table 3). Definite pyuria (10 cells or more per high-power field) was noted in 158 patients (43.2%), 93 of whom had never had symptoms of urinary infection. When the 77 cases of infection previously mentioned are included, it becomes apparent that at the time of their initial examination nearly half of our patients had previously had or then had evidence of infection.

Renal function was impaired in 164 (47.0%) of 351 patients whose renal function was evaluated. Tests em-

and brother of one patient died of "kidney trouble" during the sixth decade of life, and seven siblings and five members of the mother's family of another patient had "kidney trouble" and high blood pressure. In 55 cases there was no family history of renal disease. In the remaining 160 cases a familial history of renal disease was not mentioned in the clinical history. It is assumed that the family history was probably negative in this respect in these cases.

As previously mentioned, Bagg [2] stated that congenital renal anomalies were inherited as a Mendelian recessive trait, and the literature contains numerous accounts of the familial tendency in polycystic disease. Crawford [7] cited one family in which the disease was traced through five generations with 17 of 40 members so afflicted, 7 of 9 siblings in the fifth generation having polycystic disease. In other series, 9 of 27 members in four generations [8] and 12 of 24 members of two generations in a family in which the disease could be traced back four generations [9] were reported. In one of our cases, the disease had manifested itself in three generations. The patient's sister had polycystic disease, her mother and four of her mother's five siblings had all died in their fifth decade of life of kidney trouble, and her 21-year-old son also had polycystic disease. She was unable to provide information concerning her maternal grandparents.

Female	163	44.5

One patient, not included in the present series because he was seen initially in 1949, nevertheless warrants description because his identical twin brother had succumbed to polycystic disease within two years of the similar death of our patient. The parallelism in their clinical courses was remarkable.

REPORT OF A CASE

A 36-year-old white man was seen at the Mayo Clinic in July, 1949, because of loss of weight, occasional nausea, and anorexia. Five years previously he had had one episode of colic in the left flank and gross hematuria, lasting two to three hours. His twin brother had several similar episodes of hematuria in 1942 and 1943, at which time the diagnosis of polycystic disease had been made elsewhere. He had high blood pressure, and finally, in 1948, at the age of 35 years, had succumbed after a "stroke." After the diagnosis of polycystic disease in his brother's case, urographic studies done elsewhere on our patient had disclosed similar polycystic changes. Since then, hypertension had increased in severity.

On admission blood pressure was 164 mm. Hg systolic and 120 mm. diastolic. Kidneys were enlarged bilaterally to the size of a grapefruit. Funduscopy revealed marked narrowing of his retinal arterioles with focal constrictions and slight hypertensive sclerosis. The value for blood urea was 72 mg. per 100 cc. and for hemoglobin 11.2 gm. per 100 cc., with an erythrocyte count of 3,300,000 cells per cubic centimeter. Urinalysis revealed albuminuria, erythrocyturia, and pyuria of grade 1 based on a grading of 1 to 4. The specific gravity of urine was 1.007. Excretory urography demonstrated bilateral delay and decreased function with diagnostic changes of polycystic disease. The patient was treated with transfusion and a high intake of fluid and discharged to go home. In November, 1950, he suddenly suffered from a vise-like substernal pain and was admitted to his local hospital in shock with a diagnosis of acute myocardial infarction. He recovered somewhat, but seven days later suddenly died.

At autopsy a dissecting aneurysm of the ascending thoracic and abdominal aorta with intimal tear at the root of the aorta and rupture into the pericardial sac with hemopericardium were found. The right polycystic kidney weighed 1,575 gm. and the left 1,275 gm.; almost all of the renal parenchyma had been destroyed. Myocardial hypertrophy and renal and cerebral arteriosclerotic changes, grade 2, were also noted.

Reason,[10] in 1933, reported the cases of identical twin sisters who had died at ages 43 and 51 years of polycystic disease. He also cited several other reports of polycystic disease occurring in twins.

CLINICAL DATA

Symptoms.—The clinical picture of polycystic renal disease is variable and depends on the stage when the patient presents himself for examination. The onset may be insidious, and the patient may be totally unaware of his affliction until a physician, during a routine checkup, discovers a renal tumor, hypertension, pyuria, or microhematuria and establishes the diagnosis. In some cases the kidneys are almost completely destroyed before symptoms are noted. In our series 133 patients had no symptoms referable to the polycystic disease at the time of initial diagnosis. In other patients symptoms either developed slowly or appeared suddenly and were severe with progressive renal failure and a rapid downhill course. The more commonly noted symptoms will be considered.

Pain was described as a dull or nagging ache by 130 patients. It usually was unilateral and probably due to the excessive weight of the kidney producing tension on the renal pedicle, increased intracystic pressure, intracystic hemorrhage, or mechanical pressure of the cysts on adjacent organs. Occasionally, pain was noted only during episodes of pyelonephritis. In 33 patients the pain was colicky in type, unilateral, and almost always associated with either gross hematuria and the passage of clots or with concomitant renal calculi. Thus, 163 (44.5%) of our patients complained of pain when initially examined. Of 75 patients in whom pain was not an initial complaint and in whom follow-up information concerning its presence or absence was available, 21 later had typical pain. Pain, then, usually occurs at some time in the majority of cases of polycystic disease, and it is by far the commonest associated symptom.

Gross hematuria, noted in 115 of our patients, was usually episodic, of brief duration, and precipitated in most instances by trauma or excessive physical exertion.

* Based on traced patients. Inquiry as of Jan. 1, 1954.
† Patients with microhematuria and pyuria are excluded.
‡ 39 patients with microhematuria only and 115 with gross hematuria are included.
§ 93 patients with asymptomatic pyuria and 77 with symptoms of urinary infection are included.

The cases in which neither gross hematuria nor symptoms of urinary infection were evident, but in which examination of the urine revealed the presence of microhematuria or of pyuria with urinary infection, have not been included here. These cases will be considered later.

Gastrointestinal symptoms, such as nausea, vomiting, and anorexia, were reported by 28 patients (7.7%). Renal insufficiency and uremia, with loss of weight, weakness, easy fatigability, edema, and other signs of renal failure were invariably associated. These symptoms were relatively terminal in the disease, and their rarity in our series was primarily the result of diagnosis before their occurrence. Follow-up data were inadequate concerning the occurrence of these symptoms since they closely preceded the death of the patient and later correspondence usually revealed only the date of death without reference to the terminal clinical course.

Signs.—The frequent association of hypertension with polycystic disease was first pointed out by Braasch [11] in 1916. For the present discussion we arbitrarily classified the blood pressure of those patients whose systolic pressure exceeded 160 mm. Hg or the diastolic exceeded 90 mm. as moderately elevated, and that of patients whose blood pressure exceeded 200 mm. systolic and 110 mm. diastolic as severely elevated. The distribution of our patients accordingly is shown in table 2.

Fifty-five per cent of patients were found to be hypertensive, and 35 patients (50%) initially normotensive had elevated blood pressure at the time of reexaminations. It would appear, therefore, as if at least four-fifths of patients become hypertensive during the course of the disease. Palpable enlargement of the kidneys was demonstrated bilaterally in 187 patients (51.1%) and unilaterally in 98 patients (26.8%). Three of these had only a solitary kidney, the other having been surgically removed previously. Of the 81 patients in whom no enlargement was palpable initially, 24 later returned for examination, at which time 12 (50%) had palpable enlargement, either unilaterally or bilaterally. Thus, the vast majority of patients had palpable enlargement of at least one, and usually of both kidneys.

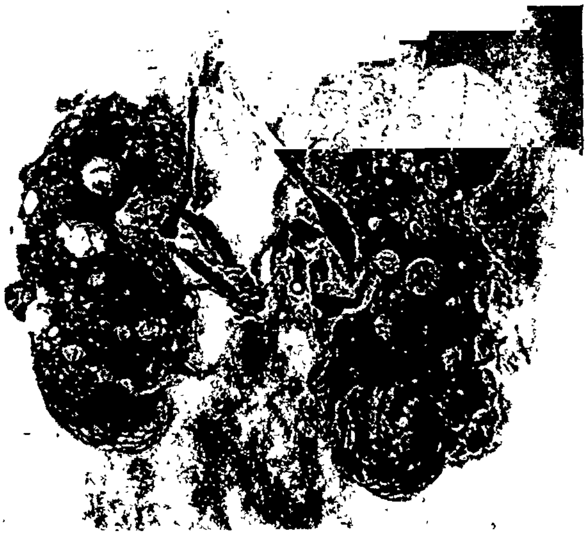

Fig. 1.—Polycystic kidneys from a 71-year-old man who died in renal insufficiency with uremia.

Laboratory Studies.—Albuminuria was found in the majority of patients and a specific gravity of urine of less than 1.010 was frequently noted. Microhematuria was found in 109 patients, of whom 39 had never experienced gross hematuria (table 3). Definite pyuria (10 cells or more per high-power field) was noted in 158 patients (43.2%), 93 of whom had never had symptoms of urinary infection. When the 77 cases of infection previously mentioned are included, it becomes apparent that at the time of their initial examination nearly half of our patients had previously had or then had evidence of infection.

Renal function was impaired in 164 (47.0%) of 351 patients whose renal function was evaluated. Tests employed were determination of blood urea in 302 cases, the phenolsulfonphthalein excretion in 12 cases, or concentration of dye at the time of the excretory urogram in 37 cases. Follow-up determinations of blood urea were made on 63 of the patients who had normal values initially; 34 (54%) then had elevated values. Renal insufficiency thus may be considered a common occurrence as the disease progresses. No patient with renal impairment had normal values for blood urea later, although mild insufficiency persisted for many years in a few cases before progressing to renal failure and death.

---

[11] Braasch, W. F.: Clinical Data of Polycystic Kidney, Surg., Gynec. & Obst. 23:697-702 (Dec.) 1916.

Moderate or severe anemia was noted in 102 cases (28.7%) of 355 cases in which determinations of hemoglobin were carried out. Follow-up examinations on 66 patients who originally had normal values for hemoglobin revealed anemia in 25 (37.9%). In almost all patients anemia was associated with renal insufficiency and the increasing incidence of anemia with progression of the disease parallels closely the similar increase of renal insufficiency, as noted previously.

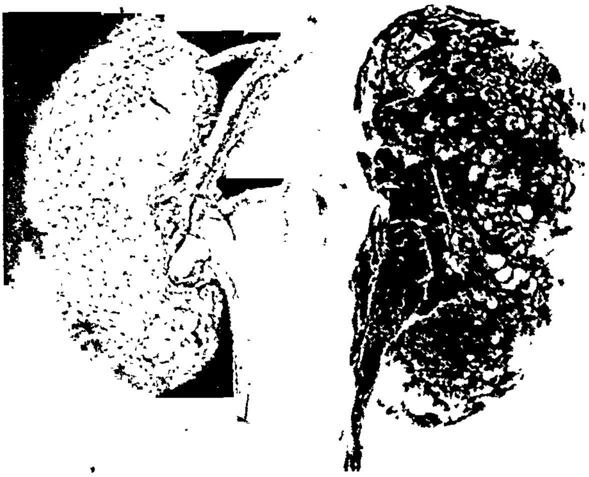

Fig. 2.—Unilateral polycystic disease in a 47-year-old man.

The characteristic urographic picture of polycystic renal disease, as described by Braasch and Emmett,[12] consists of extensive elongation and irregular enlargement of the calices, occasionally so extensive as to give a fantastic appearance to the pelvis. Unlike the picture seen with neoplasm or large simple cysts the pelvic outline itself is seldom greatly altered. The changes are usually bilateral, and this factor permits ready differentiation from large or multiple cysts or from neoplasm. Also, multiple calices are usually involved, often with a crescentic deformity of the caliceal tip due to the pressure of an adjacent cyst. Retrograde pyelography, by virtue of clearer visualization and more complete filling, will frequently permit a correct diagnosis when the excretory urogram is equivocal. When the urographic changes are largely unilateral, confusion with multiple simple cysts or renal neoplasm is possible. A unilateral occurrence has been established in approximately 8% of cases of polycystic renal disease by Bell,[6] in whose series 8 of 14 such cases occurred in adults. Polycystic changes may develop in time in the other kidney in many cases in which clinical evidence indicates unilateral involvement. This is particularly likely to occur after nephrectomy. At autopsy in 3 of our 35 cases the disease was unilateral; 2 of the patients were adults (fig. 2).

Urographic studies, either excretory urography or retrograde pyelography, were employed in 240 cases and were diagnostic in 189 of these cases (78.8%). Ten of the 51 patients whose condition was urographically indeterminate at first later had urographic studies at which a diagnosis of polycystic disease was made. The 126 patients on whom urographic studies were not performed were almost without exception patients with elevated values for blood urea that precluded excretory urography, and the clinical diagnosis was sufficiently evident so that urographic studies were unwarranted.

TABLE 3.—*Laboratory Data in Three Hundred Sixty-Six Cases of Polycystic Renal Disease*

Associated calculi	
Unilateral	31
Bilateral	3
None	267
Unknown	65
Total	366

Associated nephrolithiasis was noted in 34 cases (14.1%) and was bilateral in 3 cases. The not infrequent occurrence of nephrolithiasis in polycystic renal disease is probably the result of urinary stagnation and infection with subsequent formation of calculi.

PROGNOSIS

The over-all survival statistics in our group of cases is outlined in table 2. The normal 5-year survival rate for a group of individuals 44 years of age is 96%,[12] and the 10-year survival is 90.5%. The 5-year survival in our series was 56% of 288 patients traced, and the 10-year survival was 38% of 248 patients traced. Obviously, the majority of patients with polycystic renal disease do not live a "normal" life span. Nevertheless, in our series 11 patients lived more than 20 years, and 1 patient was still living at the time of our study 26 years after the initial diagnosis. Prognostic criteria, therefore, are important. In table 2 the length of survival in our cases is related to some of the various clinical manifestations of polycystic renal disease.

---

[12] Braasch, W. F., and Emmett, J. L.: Clinical Urography: An Atlas and Textbook of Roentgenologic Diagnosis, Philadelphia, W. B. Saunders Company, 1951, p. 414.

The patient who is asymptomatic or complaining only of lumbar pain tends to fare better from the standpoint of longevity than the patient with urinary infection. However, the survival rate of the latter undoubtedly will be improved with use of modern antibiotic agents. Actually, since symptoms were multiple in most cases, these figures are not pure ones for the symptom involved. In our series were 36 patients whose only symptom was pain; 89% survived five years after examination at the clinic. Survival rates of patients whose only symptom was infection or hematuria approximated closely the figures given in table 2. Why patients with pain should outlive asymptomatic patients can only be conjectured. The average age for the asymptomatic group was 45 years and for the "pain-only" group 44 years, so earlier diagnosis or younger patients are not the explanation. Hematuria is definitely an unfavorable symptom, indicating a somewhat more advanced stage of the disease with a poorer life expectancy. Gastrointestinal upset, associated with advanced renal insufficiency as it invariably is, is a most ominous symptom; all of our patients died within three years and only two were living beyond one year after diagnosis at the clinic.

Hypertension of any marked degree augurs poorly for the patient. Anemia also indicates a serious situation. However, the physician can best base his prognosis on the presence or absence of renal insufficiency as evidenced principally by the blood urea or other similar determination. In our series 85.3% of patients with normal renal function lived five years, whereas only 21.2% of the patients with renal insufficiency lived five years.

Thus, in the majority of cases it should be possible for the physician to prognosticate fairly accurately when all of these clinical aspects, and particularly the blood urea, are taken into consideration. However, the behavior of polycystic renal disease is often totally unpredictable, and any prognosis must be given cautiously and accepted with some reservation, as even the apparently sickest patient may occasionally survive well beyond the most optimistic expectation. The reverse, of course, is also occasionally true. Undue pessimism should certainly be avoided. Nine of our patients (25.7%) who came to autopsy had passed their 60th year and five of them were more than 70 years old at the time of death. In our series also were 32 patients 60 or more years old at the time of admission, so a normal life span is not unusual.

Death results most commonly from renal failure with uremia, myocardial infarction, cerebrovascular accident, or cardiac decompensation secondary to hypertensive cardiovascular disease. One-half of our patients who came to autopsy died accordingly, with renal insufficiency as the predominant cause, and the majority of follow-up reports of death listed these same causes most commonly.

TREATMENT

Nonsurgical.—Treatment of polycystic renal disease may be either surgical or nonsurgical, but in most cases nonsurgical treatment is adequate. Measures employed are largely supportive and are designed to relieve the usual complications of infection, renal insufficiency, anemia, and hypertension. Modern chemotherapeutic or antibiotic agents should be employed early in any systemic infection or at the first signs of urinary infection. A high daily intake of fluid should be encouraged, and a low-protein diet may be helpful. Transfusions are given if the hemoglobin becomes low. The patient should be encouraged to rest adequately and relieve the tensions of daily life in so far as possible.

Surgical.—The usually cited indications for surgical intervention and the procedures employed are as follows: (1) nephrolithiasis with pain or obstruction, for which pelviolithotomy and cyst puncture are usually performed; (2) renal or perirenal infection, for which nephrostomy and drainage with either cyst puncture or nephrectomy is needed; (3) severe spontaneous or traumatic hematuria, or intractable pain, necessitating either cyst puncture or nephrectomy; (4) impending renal insufficiency or increased hypertension without renal failure, for which cyst puncture may be of aid, and (5) associated neoplasm or tuberculosis, which requires nephrectomy.

Most of the surgically treated patients in our series have been reported on previously,[13] but because of longer follow-up now possible, data are included herein. Surgical exploration was incidental to other operations in all 17 such cases. Cyst puncture was performed on 28 patients and was repeated ipsilaterally on 2 of them 6 and 18 years later and contralaterally on 2 others 6 and 7 years later. Thirty patients underwent nephrectomy, three of whom had nephrectomy secondarily after a previous cyst puncture. Two additional patients had nephrectomies originally, with a cyst puncture on the contralateral kidney 6 and 15 years later, while a third patient had cyst puncture initially and contralateral nephrectomy 8 years later. Simultaneous heminephrectomy and cyst puncture were done in one case. Thus, excluding the 17 cases in which exploration only was performed, 62 patients underwent 69 definitive surgical procedures. There were two operative deaths; both patients had preoperative azotemia. Both deaths followed nephrectomy; one was due to postoperative ileus and renal insufficiency and the other to infection and renal insufficiency after removal of a pyonephrotic and polycystic kidney.

TABLE 4.—*Indications for Operation in Polycystic Renal Disease*

Purpose or Indication	Nephrectomy	Cyst Puncture	Nephrectomy and Cyst Puncture	Heminephrectomy and Cyst Puncture
Rule out neoplasm	12	12	1	..
Improve function or symptoms	4	8	4	..
Nephrolithiasis	2	1	1	..
Renal infection	4	1	..	1
Nephrolithiasis and infection	1	..	..	..
Hydronephrosis	1	1	..	..
Incidental to other operation	..	1	..	..
Not known (operation elsewhere)	6	8	..	..
Total	30	32	6	1

The indications for surgical intervention are listed in table 4. The commonest indication for operation was to rule out neoplasm; in two of these cases an associated hypernephroma was found. On the whole, the condition of the surgical group was better than that of the nonsurgical. In the surgical group the average age was 42.7 years, 23% had anemia, 35% hypertension and 24% renal insufficiency, whereas in the nonsurgical group the average age was 44.2 years, 29% had anemia, 61% hypertension, and 51% renal insufficiency. The over-all survival in the surgical group consequently was better. Of the 58 patients traced five years, 45 (77.6%) had lived five years.

[13] Walters, W., and Braasch, W. F.: Surgical Aspects of Polycystic Kidney: Report of Eighty-five Surgical Cases, Tr. Am. A. Genito-Urin. Surgeons 26: 385-393, 1933.

A comparison of the survival statistics of the two principal surgical procedures in regard to the various clinical manifestations of the disease is shown in table 5. Of three patients who underwent nephrectomy and cyst puncture procedures on the contralateral kidney, two are still living 12 and 17 years after the nephrectomy and the third died 21 years from the date of his initial procedure, the cyst puncture. The patient subjected to heminephrectomy and unilateral cyst puncture died eight years after operation.

Comparison of the subdivided surgical group is difficult because of the comparatively few surgical cases. Apparently the removal of a functionless, destroyed, or infected kidney of a patient with normal renal function, blood pressure, and hemoglobin does better his chances for survival. If abnormal conditions obtain that indicate a more advanced stage of the disease, most writers agree that nephrectomy is probably not indicated, particularly in cases of renal insufficiency. Our cases are too few in these respects to draw any valid conclusions.

TABLE 5.—*Comparison of Survival Rates After Nephrectomy and Cyst Puncture with Survival Rates in Nonsurgical Cases: Relationship of Clinical Signs* *

Type of Therapy	Total in Series	Renal Function		Blood Pressure			Hemoglobin		
		Normal	Impaired	Normal	Moderately Elevated	Severely Elevated	Normal	Moderately Decreased	Severely Decreased
Nonsurgical (average age, 44 yr.)									
Traced patients	230	111	105	91	76	56	151	48	24
5-yr. survival rate, %	50.0	82.9	20.0	57.1	53.7	39.3	64.9	29.2	12.5
Nephrectomy alone (average age, 40 yr.)									
Traced patients	28	21	7	19	5	2	21	4	2
5-yr. survival rate, %	82.1	95.2	42.9	94.7	40.0	50.0	90.5	50.0	50.0
Cyst puncture alone (average age, 45 yr.)									
Traced patients	26	20	6	15	7	4	20	5	1
5-yr. survival rate, %	69.2	85.0	16.7	93.3	42.9	25.0	75.0	60.0	....

* 4 patients treated with multiple surgical procedures are excluded from this analysis.

It would appear as if surgical intervention is rarely indicated in polycystic renal disease except for the complicating situations requiring it that were listed earlier. The cyst puncture, aside from some improved survival in the nonhypertensive group of patients, produced no remarkable results. In the presence of renal insufficiency, anemia, severe hypertension, or similar conditions, such surgery does not seem indicated. Recently[14] it has been shown that many of the cysts in adults are functioning elements and their puncture results in further depression of renal function. This observation bears out the previously cited findings of Lambert,[4] and lends support to our clinical findings in this regard. The symptomatic relief afforded by puncture is usually temporary. Incidental to other operations it may be well to do cyst puncture, but as a primary procedure, except for the circumstances enumerated earlier, results do not seem to merit even the minimal operative risk.

The removal of a functionally impaired or damaged kidney from a patient with apparently little or no involvement of the contralateral kidney and with normal renal function is probably indicated, but in the face of renal insufficiency, severe hypertension, or anemia, it would be difficult to justify such a procedure unless necessitated for other reasons. Needless to say, nephrectomy should never be done unless the function of the contralateral kidney has been ascertained preoperatively.

SUMMARY

The 366 cases of polycystic disease of the kidneys encountered at the Mayo Clinic in 20 years (1925 through 1944) were reviewed and follow-up data were obtained. The pathogenesis of renal polycystic disease is not entirely understood. It has congenital and familial aspects. Lumbar or upper abdominal pain, renal infection, hematuria, and gastrointestinal symptoms are the commonest symptoms of this disease. Hematuria and gastrointestinal symptoms indicate a poor prognosis, the latter being particularly ominous in this respect. In the majority of cases one or both kidneys will be palpably enlarged and moderate or severe hypertension will usually be present. Severe hypertension indicates an advanced stage of the disease.

The most reliable and consistent prognostic sign in our series was the presence or absence of renal insufficiency. Renal impairment, with or without anemia, indicated that the prognosis was particularly poor.

Operation usually is indicated only when complications require it. Occasionally, however, when only one kidney is primarily involved and is apparently functionless, its removal may add to the survival and comfort of the patient provided that the contralateral kidney is not impaired. Cyst puncture may occasionally be employed incidental to other surgical procedures, but, aside from the rare instances in which it is necessitated for the relief of symptoms resulting mechanically from the size of the cysts, we could demonstrate no valid primary indication warranting this procedure. The hope that this operation might prolong life in the presence of early renal insufficiency was not supported in this study.

We particularly wish to emphasize that it is not too unusual for a patient with renal polycystic disease to live an essentially normal life span. The prognostic factors discussed in this paper may permit the physician to so encourage his patient. We hope that undue pessimism concerning this disease will be less prevalent in the future.

PNEUMONIA IN NEWBORN INFANTS

Alexander J. Schaffer, M.D., Milton Markowitz, M.D.
and
Anthony Perlman, M.B., B.Ch., Baltimore

Pathologists have recognized since late in the 19th century that pneumonia was responsible for the deaths of many newborn infants.[1] Since many who died were stillborn or died within the first few hours or days of life, it was obvious that a certain proportion must have acquired pneumonia in utero. Pediatricians have virtually ignored this observation. Pneumonia is seldom diagnosed; indeed, it is rarely considered as a possibility in the differential diagnosis of respiratory illness in the early neonatal period. In this report we shall attempt to demonstrate that this condition is recognizable, given a high enough index of suspicion, and that it is not invariably fatal. In addition, we suggest that some cases are preventable and that vigorous treatment may be lifesaving.

There is a considerable percentage of stillborn and newborn infants in whom evidence of inflammation of the lungs has been discovered in large series of consecutive autopsies. Browne [2] (1922) found it in 26% and Macgregor [3] (1939) in 32%. Hook and Katz [4] (1928) reported a figure as high as 51%. Since 1940 the incidences reported have been considerably lower. D'Esopo and Marchetti [5] (1942) found 7% of perinatal deaths due to pneumonia and Bundesen and collaborators,[6] (1952) approximately 8%. In one of the hospitals from which our data have been collected, 76 autopsies on stillborn and newborn infants were performed from 1951 to 1953. Pulmonary inflammation of some degree was found in 27 (35%), was considered a contributory cause of death in 7 (9%), and was the sole cause of death in 6 (8%). Therefore, we may assume that roughly 1 out of every 12 perinatal deaths is caused by pneumonia.

MATERIAL AND DIAGNOSES

In this study we have analyzed the data concerning 38 babies who died within the first month of life with inflammatory changes in the lungs. Of these, 25 died and autopsy done in one hospital, 13 in another. All had been examined repeatedly during life and detailed contemporaneous notes had been written. As 5 of the 38 infants were stillborn and 23 were liveborn and lived no longer than three days, we felt free to assume, following Potter,[7] that the cause of death in these was probably of intrauterine origin. These 28 were analyzed for possible etiological factors associated with intrauterine pneumonia. The remaining 10 died between the 4th and 28th day of life. In many of these, pneumonia was postnatally acquired.

For the study of the clinical characteristics of intrauterine pneumonia, the total of 38 cases was perforce drastically reduced. The five stillborn infants were omitted. The 10 who died after the third day of life were omitted, as were 13 more who demonstrated in addition to pneumonia at postmortem examination either hyaline membrane formation, intracranial hemorrhage, or congenital malformation. The remaining 10 cases were considered pure pneumonia, almost surely acquired in utero or in the birth canal. Although the series is small, the presence of accurate clinical notes makes it worthy of discussion. We shall also present the histories of two patients who recovered from what we believed to be congenital pneumonia.

We shall not discuss in this report, because of limitation of space, the clinical features of the many varieties of postnatally acquired pneumonia. That form due to aspiration of food or gastric contents is familiar to all. The varied manifestations of micrococcic pneumonitis have been thoroughly described in many reports.[8] The group caused by less usual organisms is exemplified by the communication of Miller and associates,[9] who have recently reviewed the literature and reported another case of Klebsiella pneumoniae (Friedlander's bacillus) in the newborn infant. Adams [10] has described epidemics of respiratory infection that he believes are caused by a virus. In general, the diagnosis of these postnatally acquired infections presents less difficulty. Before attempting to delineate a composite clinical picture of intrauterine pneumonia, we shall present a few representative case histories. The first is that of a stillborn infant, the next two of full-term liveborn infants, and the final two of premature liveborn infants.

REPORT OF CASES

CASE 1.—A full-term 8 lb. 5 oz. (3,770.5 gm.) female infant was stillborn. The mother was an obese 27-year-old primipara. Membranes ruptured spontaneously 47 hours before delivery. Total labor lasted three and a half hours, second stage one hour. Fetal heart was not heard when labor commenced. At birth the baby was flaccid, failed to breathe, and would not respond to any form of resuscitation. Autopsy showed widespread intrauterine pneumonia.

CASE 2.—A full-term 7 lb. (3,175.1 gm.) female infant was born to a 30-year-old primipara who developed marked intrapartum hypertension. Membranes ruptured, labor began but

progressed poorly, and after 38 hours cesarean section was performed. The infant was cyanotic at birth and gasped a few times only. In the Bloxsom apparatus respirations were established. At 3 hours respirations were grunting in character, but air exchange was good and no rales were heard. She was transferred to the Isolette incubator with oxygen at 2 liters per minute and high humidity. Penicillin and streptomycin therapy was begun. At 8 hours respirations were rapid and shallow and temperature rose to 102 F. Rigidity, then twitchings, appeared. Temperature rose to 104.6. Death occurred at 14 hours. Autopsy showed widespread pneumonia.

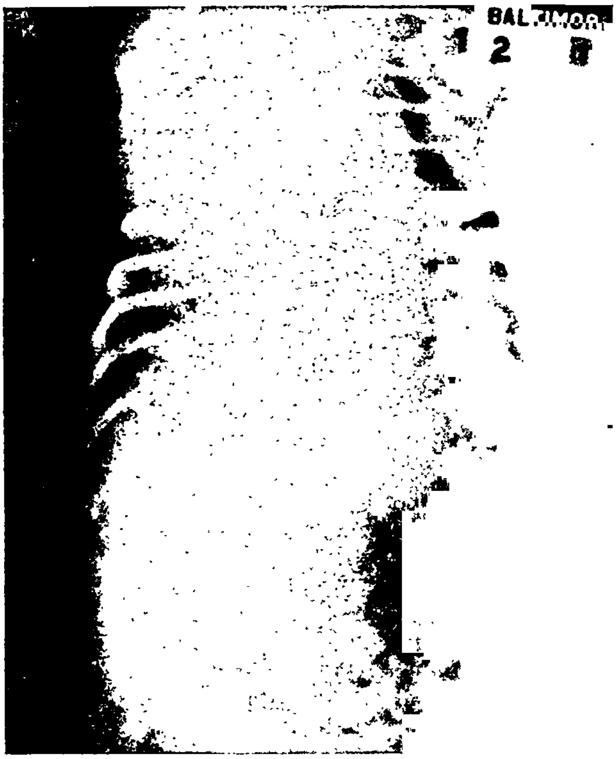

Fig. 1 (Case 3).—X-ray of chest showing massive consolidation of both lungs, which spares only the peripheral portions.

Case 3.—A full-term 9 lb. (4,082.3 gm.) female infant was born to a 30-year-old primipara. Pregnancy had been uneventful except that mother had a hemorrhoidectomy two weeks before term. Membranes ruptured four hours prior to delivery. Total labor lasted five hours, the second stage two hours. The infant cried and breathed spontaneously after birth, but the color looked pale and gray and the obstetrician placed her immediately in the Bloxsom apparatus. Two hours after birth respirations were noted to be grunting, and this increased over the next 10 hours. Slight cyanosis was visible even with the infant in the Isolette. At 16 hours color was grayish and cyanotic, temperature was 101.6 F, and respirations were rapid and shallow with slight sternal retraction. Percussion note was dull everywhere, and many fine rales were heard throughout. Air exchange was quite poor. Heart sounds were poor, and the liver edge descended to two fingerbreadths below the costal margin. Penicillin and streptomycin were given intramuscularly and chlortetracycline (Aureomycin) intravenously, all in full therapeutic dosage. Temperature rose to 102.2 F. X-ray showed very little aerated lung, limited to the periphery (fig. 1). Autopsy showed widespread pneumonia (fig. 2).

Case 4.—A premature 2 lb. 9 oz. (1,162.3 gm.) female infant was born to a multipara after 30 weeks of gestation. Membranes ruptured spontaneously 30 hours before delivery; labor was very short and without incident. Born at home, she is said to have looked well and to have cried and breathed spontaneously. At 2 hours of age, when admitted to the hospital, she showed facial edema and ecchymoses of face and extremities, and rapid respiration with mild retraction was observed. In the chest poor expansion, distant breath sounds, and fine rales at both bases were noted. Temperature remained 93.5 to 95 F throughout. Respirations became more rapid and grunting, but retraction did not increase. Death occurred at 10 hours of age. Autopsy showed marked atelectasis and widespread pneumonia.

Case 5.—A premature female infant was the result of the seventh pregnancy of a mother who had had four or five episodes of bleeding lasting one or two days since the fourth month of pregnancy. Membranes had ruptured eight days before delivery. Born in the 28th week in another hospital, the infant weighed about 2 lb. (910 gm.) and is said to have breathed spontaneously. Her color in the incubator was fair. At one and a half hours, she became apneic and nikethamide (Coramine) was given. One hour later she was admitted to the Johns Hopkins Hospital. She was deeply cyanotic, and thick mucoid secretion was suctioned from the nasopharynx. In the Isolette, color improved, but at 12 hours she became hypertonic and suffered apneic periods lasting one or two minutes. After this, cyanosis persisted even when she was in the Isolette with high environmental oxygen, and respirations, rapid and shallow, were accompanied by slight retraction. Air exchange was very poor throughout, but no rales were heard. Lethargy developed and increased, muscular twitchings appeared, cyanosis deepened, and respirations became abdominal and more labored and retraction a bit deeper. Temperature remained subnormal throughout. Death occurred at 27 hours

CLINICAL FINDINGS

After discarding all cases with coexisting intracranial hemorrhage, hyaline membrane disease, congenital malformation, and any other disorder that might confuse the picture we were left with 10 cases of pure pneumonia. Of these, six infants were full term, four were premature. The following observations were made, but because of the small size of the series any conclusions drawn from them must be considered tentative. None of the full-term infants appeared well or behaved in normal fashion at birth. They were described either as limp and

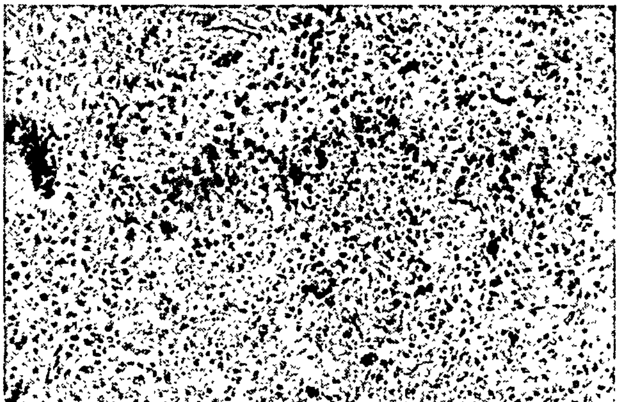

Fig. 2 (Case 3).—Photomicrograph of lung showing consolidation and polymorphonuclear infiltration (× 150).

pale, flaccid, of poor color, or cyanotic. Crying and spontaneous breathing were delayed in all but one, and in this one the color was so obviously poor that the obstetrician placed him in the Bloxsom apparatus at once. In one regular respiration was established after 2½ minutes, in two others only after 10 minutes. It was deemed necessary to place all the full-term infants in some form of resuscitating apparatus—Kreiselman, Rockette, or Bloxsom. The four premature infants were born at home or in another hospital; their immediate postnatal behavior is less well known. One infant was cyanotic at birth; the others were said to have been in good condition at birth. All were deeply cyanotic by the time of admission to hospital at 2, 2½, 3, and 10 hours of age respectively.

When spontaneous breathing was established, the pattern was usually described as rapid and shallow, at times as rapid and grunting. Irregularity, with periods of apnea, was noted as the condition worsened. Retraction was absent or minimal in most, having been recorded as moderate in only 2 of the 10 infants. It never approached in degree the retraction characteristic of full-blown hyaline membrane disease. Fever was present, surprising both in frequency and, at times, in height of temperature, in the full-term group. In one the temperature rose from 102 F at 4 hours to 104.6 at 28 hours. In another it rose to 105 F at 8 hours and remained high for the entire 3 days of life. In the third it reached 99.6 to 102.2 F; in the fourth and fifth it ran between 100 and 100.8 F; and in one it was normal for the entire 2½ days except for one reading of 100 F. In the premature infants, on the other hand, the temperatures were never elevated. They were usually markedly subnormal. Cough was never present in either the premature or the full-term infants. Physical signs in the chest were variable in both the mature and immature babies. In only four were the percussion note and breath sounds normal and adventitious sounds absent. Air exchange was deemed fair or poor in five. Fine rales were heard in three, rhonchi in two more. Tubular breathing was never heard. Signs pointing toward involvement of the central nervous system, in addition to the flaccidity and retardation of breathing and crying so often present just after birth, appeared frequently some hours later in life. They were observed in 6 of the 10 infants and consisted of persistent flaccidity in 2, hypertonicity or rigidity with twitching movements in 3, and frank convulsions in one. There was evidence of heart failure in two, in the form of poor heart sounds, cardiac enlargement, and increase in size of the liver.

X-ray and laboratory data are slowly accumulating but are in this particular group sparse. No roentgenograms were made on the premature and very sick mature infants, so that only two are available. One showed diffuse clouding of both lungs with very little aerated lung limited to the periphery of the thorax. The other showed an area of consolidation in the left upper lung field and scattered opacities spreading outward from the hilum in both lung fields. We have other roentgenograms of infants not in this series that demonstrated similar alterations (fig. 3). Systematic laboratory work has not been carried out on these infants until recently. Therefore, we have too few white blood cell counts and cultures to comment with assurance. Among these only one white blood cell count was definitely beyond the limit considered normal for newborn infants, that one being 31,900 per cubic millimeter. None were remarkably low. Nose and throat and blood cultures have thus far added little information. Considerably more work is required in this area, possibly utilizing techniques other than those in conventional use.

PROGNOSIS

Potter [7] and Snyder [11] have indicated that the outlook for the infant with prenatally acquired pneumonia is hopeless. With this opinion we do not agree. We shall demonstrate several histories of infants who recovered, in whom we believe this diagnosis is the correct one.

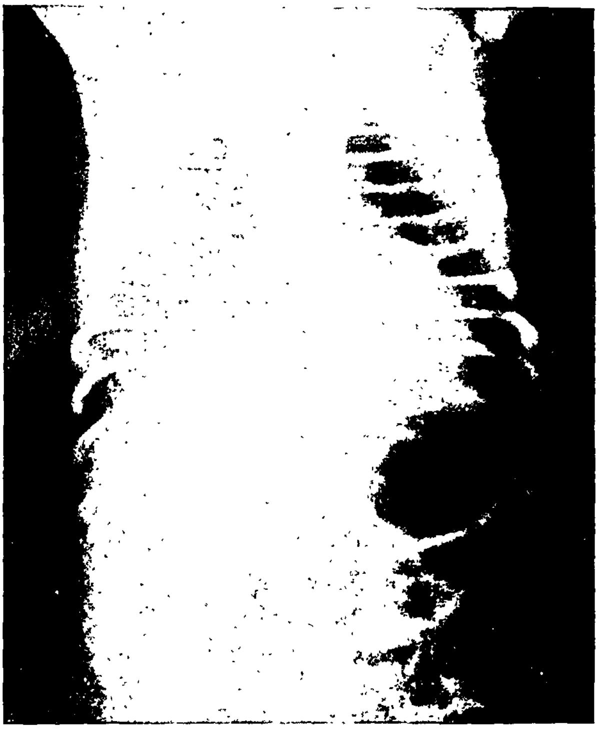

Fig. 3.—X-ray of chest showing much patchy infiltration in right lung, less in left lung.

Case 6.—A full-term 7 lb. 14 oz. (3,572.04 gm.) female infant was born to a 37-year-old multipara four days after the membranes had ruptured. Labor was induced by intravenously administered oxytocin (Pitocin) and lasted only three hours. For three days the mother had been given penicillin and streptomycin, and for the last 36 hours oxytetracycline (Terramycin) had been added. The mother had been given meperidine (Demerol) hydrochloride, 100 mg., and scopolamine, 0.6 mg., intravenously 23 minutes before delivery, following which she developed respiratory depression succeeded by hyperventilation. The infant at birth was extremely cyanotic and flaccid. She was placed in an incubator with high oxygen and humidity; the nasopharynx was suctioned; and penicillin and streptomycin therapy was started immediately. At 8 hours she was mildly cyanotic and sluggish, with hypoactive reflexes and a fair Moro response. Respirations were rapid and shallow, 45 to 60 per minute. Lungs were normal to percussion and auscultation. At 16 hours there was no change. By 33 hours her color was improved in the incubator but dusky when removed from the incubator, and respirations were 100 per minute. Poor air entry into the right lung posteriorly was noted. Respirations were unchanged in rate and character 24 hours later, but color and tone seemed improved. No rales but harsh breath sounds were heard at the base of the right lung. X-ray at this time revealed scattered foci spreading outward from the hilum and diffuse clouding of the base of the right lung (fig. 4*A*). Therapy with tetracycline (Achromycin), 50 mg. every 8 hours, was begun. At the fourth day of life she seemed slightly improved but respirations were unchanged. On the fifth day definite improvement was noted and from then on continued steadily until the ninth day when she appeared quite well. Repeat x-ray examination showed distinct clearing (fig. 4*B*). Fever ranged from 100 to 101.5 F throughout the first 5 days of life. The white blood cell count was 15,150 per cubic millimeter with 52% polymorphonuclear cells on the second day and showed no essential change on the ninth day. Nasopharyngeal culture grew a Micrococcus (Staphylococcus) pyogenes var. albus. Blood culture was sterile. Examination of the placenta revealed acute inflammation of the amniotic membranes with spread to the decidual layer.

---

[11] Snyder, F. F.: Obstetric Analgesia and Anesthesia: Their Effects upon Labor and Child, Philadelphia and London, W. B. Saunders Company, 1949.

CASE 7.—A 6 lb. (2,721.6 gm.) female infant was born to a 23-year-old primapara after 41 weeks of gestation. Pregnancy had been uneventful. Labor began spontaneously and lasted 13½ hours, the second stage lasting 1 hour. Membranes ruptured four hours before delivery. She was given no sedation later and four hours before. There had been no evidence of fetal distress. After elective low forceps extraction of the baby, crying did not occur for five minutes, and he was then placed in the Bloxsom apparatus. Examined at 6 hours of age he appeared depressed, of poor vigor, and with a weak, grunting cry. The skin and cord were meconium-stained. Respirations were rapid, 55 per minute, shallow, and with minimal retraction. Resonance over the chest was generally diminished. Air exchange throughout was poor, but breath sounds were audible everywhere. A few rhonchi but no rales were heard. He was transferred to the Isolette, with oxygen and high humidity, and streptomycin and penicillin therapy was begun. At 28 hours he became dusky when taken out of oxygen, respirations were 70 per minute, labored, but with minimal retraction. At this time there was marked dulness on the right, front, and back, and breath sounds were increased in this area. Many medium coarse rales were heard here. The left hemithorax was resonant, and only a few rhonchi were heard in the left front. Throat culture showed M. pyogenes var. aureus. The white blood cell count was 31,900 per cubic millimeter and the hemoglobin level was 19.5 gm. per 100 cc. X-ray showed diffuse clouding of both upper lung fields. Intramuscular administration of oxytetracycline was begun at this time.

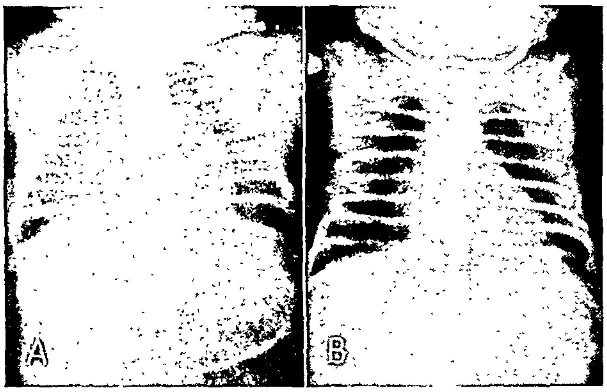

Fig. 4.—*A* (case 6), x-ray of chest showing widespread pneumonitis of both lungs diminishing from the hilum toward the periphery. *B* (case 6), same chest six days later, showing marked clearing.

At 48 hours the temperature was 100.8 F, but the infant appeared better. Respirations had slowed to 30 to 40 per minute, without retraction, and the color remained good out of oxygen. There was now some dulness to percussion over the left posteriorly, and the rales heard the day before over the right chest had disappeared. All signs disappeared by the third day of life, and the x-ray on the fourth day showed definite clearing.

ETIOLOGY AND PATHOGENESIS

The organisms that incite pulmonary inflammation in the fetal lung consist usually of one or more of those that are commonly found in the maternal vagina. How these bacteria arrive in the respiratory tract of the fetus is a much debated question. At this time we shall present our conclusions briefly, leaving for a further communication now under preparation a detailed exposition of the problem. Two facts, well-known to previous observers, are borne out in this series of 28 cases. 1. A remarkable number, 20 of 28, of the pregnancies or labors were abnormal in one or more respects. 2. Of the 28 infants, 16 were premature. This is approximately 11.5 times as many premature infants as one would expect in 28 consecutive deliveries. At least three different mechanisms appear to be operative in the pathogenesis of pneumonia of the newborn infant. The first is infection of fetal airways by the inhalation of contaminated amniotic fluid in the course of normally occurring intrauterine respiratory-like movements.[11] Contamination of amniotic fluid is usually the result of prolonged ruptured membrane time, according to Gosselin,[12] but is said to occur also after prolonged dry labor.[7] In 12 of our 28 cases time between membrane rupture and delivery exceeded six hours. In three it lasted 6 to 23 hours, in five, 23 to 47 hours, and in four, two to eight days.

The second pathogenetic mechanism is the initiation of exaggerated respiratory-like movements by some obstetric complication. This produces overdistention of portions of the fetal lung with amniotic contents, which may include meconium, and pneumonia follows. The factor commonly held responsible for exaggerated respiratory efforts of the fetus is anoxia. The table shows the distribution of obstetric complications that were present in this series.

Distribution of Obstetric Complications

	Full Term	Premature	Total
Prolonged ruptured membrane time alone..	0	3	3
Other obstetric complication alone..........	3	5	8
Combination of above.........................	6	3	9
No obstetric complication....................	3	5	8
	12	16	28

Of the 28 pregnancies or labors, 20 were abnormal in one or more respects. The complications, in addition to prolongation of labor and membrane rupture time, were numerous. They included breech presentation, toxemia, maternal bleeding, twinning, midforceps extraction, maternal diabetes, and tetanic contraction of the uterus.

We doubt that anoxia is the factor that sets off exaggerated respiration of the fetus. Snyder's [13] fetal rabbits ceased rhythmic respiration when their mothers were given low-oxygen breathing mixtures. Other observers have doubted the validity of this result, but none, as far as we can discover, have ever produced enhancement of fetal respiratory movements by the same method. Miller and Behrle's [14] recent observation that hypoxia causes depression rather than enhancement of respiration in the newborn human is further indication in this direction. Occlusion of the fetal circulation has been noted to produce gasping in many of these experimental animals. We suggest, therefore, that the trigger mechanism for gasping in utero resides not in blood chemical alterations such as low oxygen or high carbon dioxide but in some physical, possibly hemodynamic, factor. A common denominator of our long list of complications might be sudden impairment of fetal circulation. Another unanswered question in this group is the source of the bacteria that cause these pneumonias. Without prolonged membrane rupture time or prolongation of labor one would not expect the amniotic fluid to be contaminated. Might the lungs of some fetuses, otherwise normal, contain a few bacteria filtered from the blood stream during transient bacteremia, which would cause no trouble unless the lung is damaged or its circulation impaired?

---

[12] Gosselin, O., cited by Snyder.[11]

[13] Snyder, F. F., and Rosenfeld, M.: Direct Observation of Intrauterine Respiratory Movements of Fetus and Role of Carbon Dioxide and Oxygen in Their Regulation, Am. J. Physiol. **119**: 153-166, 1937.

[14] Miller, H. C., and Behrle, F. C.: Effects of Hypoxia on Respiration of Newborn Infants, Pediatrics **14**: 93-102, 1954.

For the group of eight infants in whose obstetric histories there could be discovered not the slightest deviation from normal, we are almost forced to the conclusion that transplacental infection is a third mechanism of pathogenesis. This is rendered more likely by the fact that one of three mothers had suffered exacerbation of an old osteomyelitis in midpregnancy and another had a hemorrhoidectomy two weeks before term. It is not impossible that the five very small premature infants may have acquired their infections in the birth canal rather than in the uterus, that their immature state permitted rapid extension of infection, and that their precarious balance between adequate and inadequate ventilation rendered a small amount of infection lethal.

PREVENTION

Injections of penicillin given to mothers whose membranes had been ruptured or whose labors had lasted an unusually long time failed to reduce total perinatal mortality, in Eastman's[15] experience, or in the incidence of neonatal pneumonia, according to Labate.[16] On the other hand, von Friesen[17] reported that small oral doses of sulfamerazine taken from the onset of labor until delivery reduced total perinatal mortality significantly. The question whether intrauterine pneumonia can be prevented completely or in large part by prenatal antibacterial medication is still in doubt. In our case 6, vigorous antibacterial therapy given the mother may have been of benefit. There is room for further work in this field, both by further determinations of concentrations attainable in amniotic fluid and cord blood after maternal administration of antibacterial agents and by large-scale clinical trials of combinations of drugs.

TREATMENT

Pneumonia in the early neonatal period is most likely to occur in infants (1) in cases where membranes ruptured more than six hours prior to delivery; (2) who were born after prolonged or complicated labors; (3) whose mothers suffered from toxemia or had bled profusely; and (4) who were premature regardless of the character of labor or pregnancy. Since the diagnosis is difficult to make, it would appear advisable to begin treatment on all of these shortly after birth. In this connection it must be pointed out that pneumonia was found at autopsy 13 times in this series as a complication of another serious disorder, intracranial hemorrhage, hyaline membrane disease, or congenital malformation of the respiratory or gastrointestinal tract. Since its presence was practically never suspected, perhaps it would be wise to begin vigorous treatment on all infants demonstrating signs of these conditions.

The combination of streptomycin and penicillin therapy commonly used in many clinics may or may not be the ideal choice. We have continued to use it for routine prophylaxis but always add a broad spectrum antibiotic when pneumonia is strongly suspected. On a number of occasions the improvement after the addition of chlortetracycline, oxytetracycline, or tetracycline has been gratifying. They are tolerated fairly well when given orally but often cause diarrhea or vomiting after several days. Injectable preparations are probably superior. Sulfonamides are also tolerated well, and small doses maintain high blood levels in the newborn infant. Theoretically they should be highly useful because of their potency against Escherichia coli and related gram-negative bacilli, as well as pneumococci and some micrococci (staphylococci) and streptococci. A few trials with sulfadiazine administered both orally and subcutaneously have been encouraging. Oxygen is needed for most infants but should be used only as long as absolutely required and never in concentration greater than 40%, because of the danger of retrolental fibroplasia in small premature infants. High humidity is almost surely helpful. Evidences of heart failure call for prompt digitalization. Oral feeding should be avoided while the infant is seriously ill.

SUMMARY

Pneumonia is the sole cause of death in 6% to 9% of all stillborn and newborn infants. In many instances, the disease has been acquired prenatally. Diagnosis of neonatal pneumonia is difficult and requires a high index of suspicion. The infants are commonly ill at birth. Respirations are rapid and shallow or grunting and are not accompanied by deep sternal or intercostal retraction. Cough does not occur. Fever is usually present in full-term infants but never or seldom in premature infants. Signs of central nervous system depression or irritation are frequent even when pathological studies show no brain involvement. The heart may fail. Physical signs may reveal much or little. Laboratory tests systematically performed may supply further help. The x-ray examination often reveals widespread areas of consolidation. Prognosis is not necessarily bad. Pulmonary inflammation in the newborn infant is often associated with premature rupture of membranes or prolongation or complication of labor. It also occurs when the obstetric course has been uncomplicated, chiefly in small premature infants. It is more rarely encountered in full-term infants in whom the history of pregnancy and labor has been without untoward incident. Aspiration of contaminated amniotic contents in the course of normal fetal respiratory-like movements may be one mechanism for the causation of pneumonia. Similar aspiration by abnormal exaggerated inspiratory efforts is almost surely another. Transplacental blood-borne infection may be a third. Preventive antibacterial treatment of mothers whose pregnancies or labors have been complicated in the aforementioned ways may be effective in reducing the incidence of pneumonia. Further study of this problem is required. Vigorous prophylactic treatment is advised for all infants in the three categories listed above, that is when membranes have been ruptured unduly long, when labor has been prolonged or complicated, and when premature infants are small. At the first suspicious sign of pulmonary involvement or when other serious disorders are present, a broad spectrum antibiotic should be administered in full therapeutic dosage, preferably by a parenteral route.

CLINICAL PICTURE OF PYLORIC CHANNEL ULCER

ANALYSIS OF ONE HUNDRED CONSECUTIVE CASES

Julian M. Ruffin, M.D., David H. Johnston, M.D., Donald D. Carter, M.D.
and
George J. Baylin, M.D., Durham, N. C.

The clinical picture of an uncomplicated peptic ulcer is so characteristic that the diagnosis can be made by history alone. When complications develop, this picture changes. For illustration, the patient having a pyloric obstruction from a long-standing ulcer loses the familiar "pain-food-relief" pattern. Likewise, the patient having a perforated walled-off ulcer will experience a change in the usual ulcer picture. The pain becomes severer, may be aggravated by food, and often radiates to the back. These two complications of peptic ulcer are well recognized by the profession and readily diagnosed. It is not generally appreciated, however, that an ulcer located in the pyloric channel frequently gives rise to a bizzare syndrome, not in the least suggestive of ulcer and often missed entirely.

There are conflicting opinions in the literature regarding this type of ulcer. Bockus[1] states that gastric ulcers in or near the pyloric canal have symptoms resembling those of duodenal ulcer, and Butsch[2] concurs in this belief. Eusterman,[3] on the contrary, points out that the majority of patients having a channel ulcer have the *syndrome pylorique* consisting of a short, stormy course with intermittent pyloric obstruction and painful spasm of the pylorus, and this opinion is shared by Brethwaite and associates.[4] Gutmann and Hoffmann[5] report that ulcer of the pylorus gives rise to "the most variable symptomatology," with no rhythmicity or periodicity of ulcer distress. The following study was undertaken to determine if ulcers located in the pyloric channel give rise to a recognizable clinical picture, how the diagnosis may be established, and what form of therapy should be instituted.

DEFINITION AND PATHOLOGY

The pyloric channel is that portion of the stomach lying between the antrum and duodenum, approximately 1 cm. in length (fig. 1). A channel ulcer may be defined as a benign peptic ulcer occurring in this region or immediately adjacent thereto. Pathologically this ulcer is identical with a benign ulcer occurring in other portions of the stomach or duodenum. In figure 2 the location and gross appearances of such an ulcer are shown, and in figures 3 and 4 microscopic sections through this ulcer show it to be the usual benign peptic ulcer.

MATERIAL

This study is based upon an analysis of the clinical features of 100 consecutive patients with a channel ulcer. The diagnosis in each case was established by the demonstration of an ulcer crater within the pyloric channel, either by x-ray or at operation. There were 75 men and 25 women, whose ages varied from 19 to 83, with 78% being between the ages of 30 and 60. For comparison the clinical features of an additional 100 consecutive patients having an uncomplicated duodenal ulcer were studied. Each of these patients had radiological findings consistent with an active duodenal ulcer. They were all seen during the calendar year of 1953 and were all hospitalized. The analysis of their histories was carried out in the same manner as with the group having channel ulcer. During the year of 1953, 825 patients at Duke Hospital were given a diagnosis of peptic ulcers, 166 being gastric and 659 duodenal. Of this group, there were 40 patients in whom the diagnosis of channel ulcer was made, an incidence of 4.3%.

CLINICAL FEATURES

Channel ulcer is characterized clinically by nausea and vomiting, upper abdominal pain, and marked weight loss (table 1). In this series, nausea with vomiting was the most frequent symptom, occurring in 83 of the 100 cases. Often, it was nocturnal and episodic, occurring

before meals, immediately after meals, or having no relationshp to meals. Occasionally nausea with painless vomiting was the only symptom. Atypical ulcer pain was noted in 79 of the 100 cases. This pain, as a rule, was totally different from the usual ulcer pain in that it usually was colicky in nature, unrelated to meals, and unrelieved or actually aggravated by food. In many patients the pain was constant, severe, and required narcotics for relief. Weight loss in excess of 15 lb. (6.8 kg.) occurred in 54 patients. A comparison of the clinical features of channel ulcer with those of duodenal ulcer is shown in table 2. As might be expected, typical ulcer distress occurred in 88% of the patients in the duodenal ulcer group and in only 14% of the patients having channel ulcer. It will also be noted that nausea with vomiting was the most frequent symptom in the channel ulcer group and relatively uncommon in patients with duodenal ulcer. Significant weight loss occurred in more than half of the patients having a channel ulcer, whereas this was an unusual finding in the group with duodenal ulcer.

TABLE 1.—*Clinical Features of Channel Ulcer in One Hundred Cases*

Significant weight loss	54	9
Hemorrhage	17	42
Typical ulcer pain	14	88
No pain	7	5

DIAGNOSIS

As intimated previously, the diagnosis of channel ulcer often is missed. In this series, an erroneous diagnosis was made in almost half of the patients. The commonest errors were in mistaking this syndrome for psychic vomiting or carcinoma of the stomach. Less frequently, it was confused with disease of the gallbladder or pancreas (table 3). A history of episodic nausea and vomiting associated with atypical upper abdominal distress should suggest the diagnosis of a channel ulcer. This is espe-

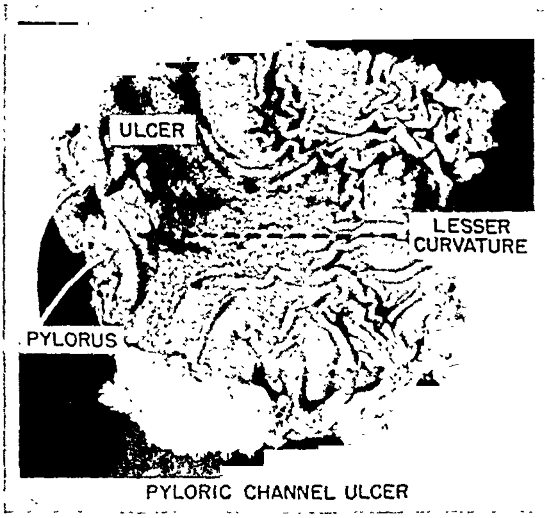

Fig. 2.—The stomach has been opened along the greater curvature. The cardiac end is to the right, pyloric end to the left. The entire circumference of the pylorus is indicated. The ulcer crater lies directly on the pyloric sphincter. It shows the characteristic "punched out" appearance with sharp, slightly overhanging margins.

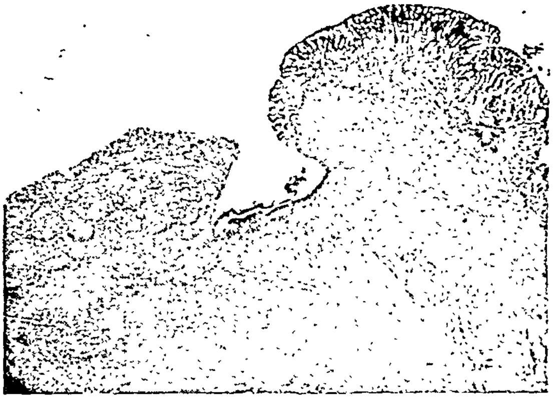

Fig. 3.—The illustration shows a complete section through a "channel" ulcer. Gastric mucosa is seen on the right side of the ulcer, duodenal mucosa on the left. In the lower right corner the muscularis is seen as a distinct layer, which becomes markedly inflamed, scarred, and distorted at the base of the ulcer. The ulcer rests directly on the pyloric sphincter (× 2.7).

cially true if these symptoms awaken the patient at night. One should remember that nausea with vomiting may be the only symptom of channel ulcer. The episodic and nocturnal character should distinguish the vomiting due to channel ulcer from that of psychogenic origin. Likewise this vomiting may be differentiated from that of pyloric obstruction, in that it consists of small amounts of gastric contents or of recently ingested food.

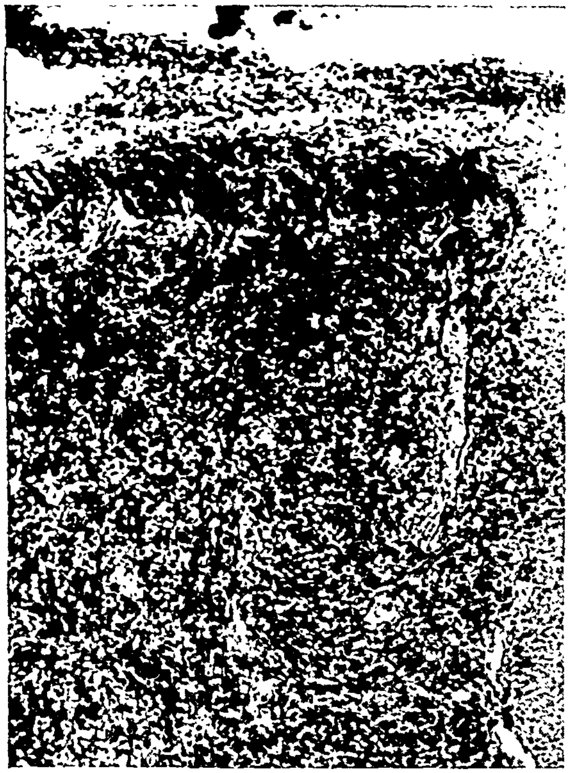

Fig. 4.—The illustration shows a higher magnification of the center of the ulcer crater. At the top is a thin layer of fibrin and polymorphonuclear leucocytes. The remainder of the picture shows the characteristic layer of granulation tissue made up of proliferating vessels, fibroblasts, and a heavy infiltration of lymphocytes and some plasma cells (× 74).

The physical examination is of little value in diagnosing this condition. The diagnosis of channel ulcer, although suspected clinically, should be confirmed radiologically. The important x-ray findings as described by Hampton and others [6] are: "1, lengthening of the pyloric sphincter, 2, distortion of the pyloric sphincter, 3, a niche located within the enlarged canal" (fig 5). In addition to these, we have noted disturbance in gastric evacuation in a large number of cases. Forty-six of the 100 patients with channel ulcer had some degree of gastric retention. In 27, the six-hour retention was estimated at 0 to 50%, in 9, 50 to 75%, and 10 patients had 75 to 100% gastric retention. In some cases gastric retention may be the only abnormal radiological finding. It is generally believed that the radiological diagnosis of channel ulcer is even more accurate than exploratory laparotomy.

TREATMENT

All patients having a channel ulcer should be hospitalized and treated intensively with a strict ulcer regimen. Overnight gastric suction and anticholinergic drugs, given parenterally, frequently result in dramatic relief of symptoms and eventual recovery. If pyloric obstruction from cicatricial narrowing is suspected, anticholinergic drugs should not be used. Channel ulcer is one of the severer forms of peptic ulcer; it may prove refractory to medical treatment and often requires surgery.

RESULTS

In this series of 100 patients having a channel ulcer, 62 recovered after intensive medical therapy, the remaining 38 requiring surgery. Contrary to a previously expressed opinion it has been our impression recently that the majority of these patients respond satisfactorily to medical treatment and that early diagnosis and intensive therapy have decreased the need for surgery.[7] Subsidence of gastric retention under treatment was inversely proportional to its severity. The six hour gastric retention, when estimated at less than 75%, subsided entirely in the majority of patients. On the contrary this retention, when estimated at 75% or more, did not subside under therapy in a single case.

REPORT OF CASES

The following case reports illustrate the pertinent aspects of channel ulcer.

Case 1.—A 29-year-old married white man was first seen at Duke Hospital in 1953, complaining of colicky epigastric pain, nausea, and vomiting of two weeks' duration. The pain occurred immediately after meals, awakened the patient at night, and was frequently relieved by vomiting. A weight loss of 15 lb. (6.8 kg.) occurred during this illness. Physical examination revealed no significant findings. Radiological study revealed only a 10% gastric retention at six hours. A diagnosis of "functional disturbance" was made, and the patient was referred to the psychiatric clinic. His symptoms gradually subsided but recurred one year later, at which time x-ray examination revealed a 40% gastric retention and a crater in the pyloric channel. The patient was then hospitalized and his symptoms rapidly subsided following intensive therapy, including night suction and parenterally given anticholinergic drugs (propantheline [Pro-Banthine] 20 mg. intramuscularly every six hours). X-ray studies of the stomach several weeks later revealed no abnormalities.

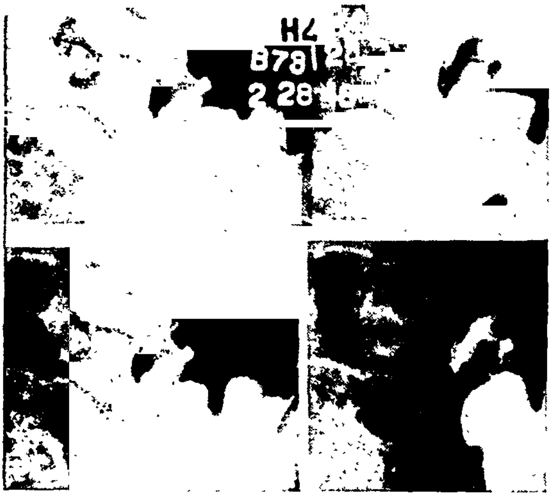

Fig. 5.—X-ray showing a large ulcer crater within the pyloric channel.

Comment.—The episodic and nocturnal character of his complaints, accompanied by a 15 lb. weight loss and a six hour gastric retention should have aroused the suspicion of channel ulcer.

[7] Texter, E. C., Jr.; Baylin, G. J.; Ruffin, J. M., and Legerton, C. W., Jr.: Pyloric Channel Ulcer, Gastroenterology 24:319 (July) 1953.

CASE 2.—A 45-year-old housewife was admitted to Duke Hospital in 1953, with complaints of intermittent colicky epigastric pain and nausea and vomiting of 17 months' duration. The pain occurred without relation to meals, was aggravated by the ingestion of food, and was only rarely relieved by milk or soda. At times the pain was constant in nature, requiring morphine for relief. A weight loss of 30 lb. (13.6 kg.) was noted. A diagnosis of carcinoma of the stomach had been made by the referring physician. Physical examination revealed no significant abnormalities. X-ray studies showed a large ulcer niche in the pyloric channel with no evidence of obstruction. The patient's symptoms did not respond to conservative management, and subtotal gastric resection was performed. The diagnosis of benign channel ulcer was confirmed at operation.

Comment.—This case again illustrates the typical features of channel ulcer of marked severity, which was unsuspected for 17 months and later misdiagnosed as carcinoma of the stomach.

CASE 3.—A 53-year-old white man experienced a sudden hematemesis without preceding symptoms in March, 1954. He was hospitalized elsewhere, and x-ray studies were said to reveal "peptic ulcer." The patient responded to therapy and was asymptomatic until August, 1954, at which time he developed severe, colicky, right upper quadrant pain associated with nausea and vomiting. These symptoms occurred without relation to meals and frequently awakened him at night. Relief of pain followed vomiting of small amounts of recently ingested food. The patient was hospitalized five weeks after the onset of symptoms, and x-ray studies revealed a large ulcer niche in the pyloric channel with a 75% six hour gastric retention. He was treated with diet, antacids, and anticholinergic drugs parenterally (tridihexethyl [Pathilon] iodide 20 mg. intramuscularly every six hours), and gastric suction, with complete subsidence of symptoms. X-ray studies several weeks later revealed healing of the ulcer and subsidence of gastric retention.

Comment.—This patient illustrates subsidence of a marked degree of gastric retention under medical therapy alone and clinical recovery without surgery.

COMMENT

There is little information in the literature on the subject of channel ulcer. The incidence of channel ulcer, 4.3% of all peptic ulcers seen at Duke Hospital in 1953, is convincing evidence that such ulcers are not rare. Because of the bizarre symptomatology that is frequently associated with these ulcers, the correct diagnosis often is unsuspected and many of these patients are treated as psychiatric problems. The question can be raised of whether the atypical symptoms of channel ulcer are due to the fact that this ulcer is different from the usual peptic ulcer or are they merely due to its location? Pathological study of these ulcers support the contention that they are the usual peptic ulcers and that the symptomatology must be due to their location alone. Although such ulcers give rise to a bizarre picture, there are characteristic features of this syndrome that should suggest the diagnosis and there are typical radiological findings that should confirm it. These ulcers are difficult to manage and are often refractory to treatment; many require gastric resection. It is likely, however, that their early recognition and institution of proper treatment will increase the probability of recovery under medical management and lessen the need for surgery.

CONCLUSIONS

Channel ulcer is one of the severer types of peptic ulcer. It gives rise to a recognizable clinical syndrome with characteristic radiological findings. Strict medical treatment supplemented by gastric suction and parenteral use of anticholinergic drugs is highly effective in many cases. However, surgery is frequently required.

DIAGNOSTIC PROBLEMS

PRESENTATION OF CASE

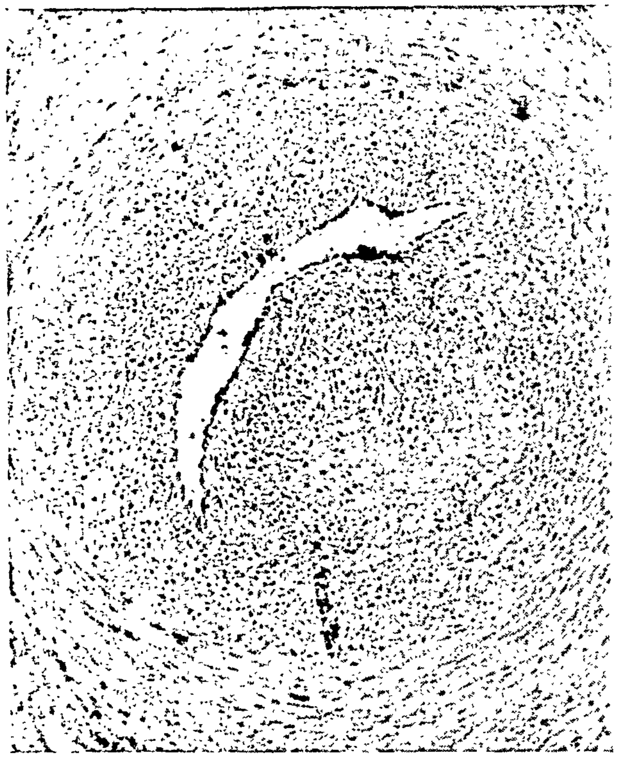
Calvin H. Plimpton, M.D.
and
S. Raymond Gambino, M.D., New York

A 30-year-old man was admitted on Nov. 17, 1954, because of abdominal pain and psychotic behavior of 24 hours' duration. About four months before admission he had a chest pain that responded to some "green pills" in two to three hours. There was no dyspnea. Three months before admission, he again had pain in the chest relieved by pills. He was then well until Oct. 28, when he had a sudden left-sided grand mal seizure. When he regained consciousness his left arm and leg felt numb, but by the next morning these symptoms had disappeared. He was first seen here on Nov. 2 in the neurology clinic, where the general examination was normal except for an equivocal Babinski's sign and questionable left-sided weakness and hyperreflexia. On the morning of Nov. 17, while on his way to the hospital for roentgenograms, he suddenly complained of abdominal pain and began to scream, strike the subway door, and tear off his clothes. A friend restrained him, but he then attempted to jump in front of a taxi. He was kept in the admitting ward for observation. Except for a temperature of 100 F, the general physical and neurological examination was normal. Hemoglobin level was 17.9 gm. per 100 cc., erythrocyte count 5,970,000 per cubic millimeter, and leukocyte count 11,950 per cubic millimeter, with 64% polymorphonuclear cells and 7% eosinophils. His urine specific gravity was 1.020, and the urine contained 1+ albumin, no sugar, and 25 to 30 leukocytes per high-power field. His blood sugar level was 182 mg. per 100 cc. He became more quiet, but in the afternoon was again agitated, tearing his clothes, and attempting suicide. His abdominal pain returned. His temperature was 97.6 F, his pulse rate was 56 per minute, his respirations were normal, and his blood pressure was 120/90 mm. Hg. There was epigastric tenderness without spasm or rebound tenderness. His leukocyte count was 11,800 per cubic millimeter, with 84% polymorphonuclear cells. His serum amylase level was normal. Roentgenograms showed a transverse heart, with clear lung fields and possibly some increase in the vascular markings. A roentgenogram of the abdomen showed gas in the colon and in one loop of the small intestine. He behaved irrationally and, despite being given 50 cc. of paraldehyde in divided doses, required restraints. His temperature rose to 103 F, and he was placed in the medical wards.

Physical Examination.—On physical examination on Nov. 18, his temperature was 100.6 F, his pulse rate was 80, his respiratory rate was 26, and his blood pressure was 110/84 mm. Hg. There was no generalized glandular enlargement. His abdomen was soft and not tender. The Mazzini test for syphilis was negative. The hematocrit was 57%, with a hemoglobin level of 21 gm.

From the Department of Medicine (Dr. Plimpton) and the Department of Pathology (Dr. Gambino), Columbia University College of Physicians and Surgeons, and the Presbyterian Hospital.

per 100 cc. The leukocyte count was 9,700 per cubic millimeter, with 64% polymorphonuclear cells. The sedimentation rate was 2 mm. in one hour. The urine specific gravity was 1.030, and the urine contained 3+ albumin, 1+ sugar, no acetone, no diacetic acid, and 4 to 7 leukocytes and 4 to 6 erythrocytes per high-power field. The serum sodium level was 131 mEq. per liter, potassium level 3.7 mEq. per liter, carbon dioxide level 16.9 mEq. per liter, and chloride level 104 mEq. per liter. His urea nitrogen was 27 mg. per 100 cc., and the nonfasting blood sugar level was 192 mg. per 100 cc. A blood culture, routine enteric agglutinations, and stool culture were negative. Urine inoculated into a guinea pig was subsequently reported as negative for leptospiral jaundice. He continued to be acutely psychotic. A lumbar puncture was normal in all respects but was followed by projectile vomiting, and the vomitus contained a few streaks of blood. On Nov. 19 he was much quieter, but was still febrile and vomiting profusely. His abdomen was distended, and there was tenderness and spasm in the epigastrium and right lower quadrant. His hemoglobin level was 17.7 gm. per 100 cc., and his leukocyte count 7,050 per cubic millimeter with 68% polymorphonuclear cells. His urine specific gravity was 1.023, and the urine contained 2+ albumin, no sugar, only an occasional leukocyte, and 4 to 8 erythrocytes per high-power field. Roentgenograms showed an atypical gaseous distention of the small intestine that could be explained by paralytic ileus or partial obstruction.



Photomicrograph of a branch of the left coronary artery, showing severe intimal sclerosis with almost complete occlusion of the lumen (hematoxylin and eosin, × 75).

Course.—At first a nasogastric tube and colon lavages seemed to help him, but on Nov. 20 his blood pressure suddenly became unobtainable. His hemoglobin level was 17.2 gm. per 100 cc., and his leukocyte count was 11,950 per cubic millimeter. His serum sodium level was 134 mEq. per liter, potassium level 4.1 mEq. per liter, carbon dioxide level 21.6 mEq. per liter, and chloride level 88.7 mEq. per liter. His urea nitrogen was 40 mg. per 100 cc. An electrocardiogram showed a sinus tachycardia but was otherwise normal. Blood, plasma, and arterenol (Nor-epinephrine) were given, and blood pressure gradually rose. His condition improved sufficiently for an exploratory laparotomy to be performed. At operation on Nov. 20, about 5 ft. of gangrenous small intestine were removed. There was no mechanical abnormality. The veins and arteries appeared thrombosed, though the superior mesenteric artery had a strong pulsation. Microscopically, the arteries appeared normal and the veins showed minute thrombi but with no evidence of organization. His temperature rose to 106.8 F and then remained almost normal. He was treated with anticoagulants. He had oliguria for several days and became icteric. His urea nitrogen rose to 206 mg. per 100 cc. and his serum potassium level to 6.7 mEq. per liter. The hyperkalemia was controlled by rectal instillations of potassium exchange resins. He seemed to improve, then died suddenly on Nov. 26.

ANATOMIC DIAGNOSIS

The heart showed severe coronary arteriosclerosis with multiple areas of almost complete occlusion (see figure). A large portion of the anterior descending branch of the left coronary artery was completely occluded by an organizing thrombus, and there was a small healed infarct at the apex of the left ventricle. The apparent age of the infarct corresponded with the history of mild chest pain four months prior to death. A mural thrombus had formed over the area of infarction, and the thrombus had undergone early organization. The patient had one large common mesenteric artery instead of separate superior and inferior mesenteric arteries. The medium-sized branches of the common mesenteric artery were occluded by emboli from the mural thrombus, producing the intestinal gangrene found at operation. The largest main branches of the common mesenteric artery were not occluded by emboli, explaining why the surgeon felt pulsations at the base of the mesentery. The small distal branches of the common mesenteric artery were likewise widely patent because the emboli were too large to enter these smaller vessels. This explains why the surgical pathologist failed to demonstrate thrombi or emboli in the specimen of resected intestine. Emboli from the mural thrombus in the heart were also found occluding branches of the renal arteries, and there were several renal infarcts of differing age. There was also an acute nephrosis, characterized by multiple small areas of necrosis and regeneration of tubular epithelium within the renal pyramids. The nephrosis was probably secondary to the prolonged hypotension and was responsible for the terminal renal failure. The mild terminal jaundice is perhaps best attributable to the extensive infarcts in the small intestine and kidneys. There were multiple small areas of acute encephalomalacia in the right superior parietal lobule, probably related to the terminal hypotension and hyperthermia. Although transient hemiparesis was an early symptom, no emboli, old cerebral lesions, or signs of cerebral arteriosclerosis were found.

COMMENT

This case illustrates the difficulties in the diagnosis of physical disease in the acutely disturbed patient. The cause for the psychosis was not found anatomically, and presumably falls into the group of toxic psychoses. We are also forcefully reminded that with arterial emboli the commonest cause is still a mural thrombus. Although this patient was unusually young, coronary arteriosclerosis is being seen in this age group. The frequently elevated blood sugar levels observed in this patient raise the possibility that he might have been a latent diabetic and hence his arteriosclerosis might have been somewhat accelerated. It is certainly dismaying that, except for the possible angina several months before, this myocardial infarct was not only "silent" clinically but also electrocardiographically. This case also illustrates the dangers of hyperkalemia in lower nephron nephrosis and the usefulness of potassium exchange resins in controlling the level of serum potassium.

CLINICAL NOTES

ETHYLENE DICHLORIDE POISONING

Roy S. Hubbs, M.D.
and
John J. Prusmack, M.D., Palo Alto, Calif.

In his treatment of patients who have ingested a toxic substance, the physician usually knows the proper steps to take in his efforts to alleviate suffering and prevent death. This is especially true of those materials more commonly swallowed by mistake, accident, or with suicidal intent. Some substances have been so incompletely studied or are so infrequently ingested that too little is known, other than general procedure, of effective methods of therapy. This is true of ethylene dichloride, a colorless liquid that was first prepared by four Dutch chemists in 1795. The substance, called "Dutch liquid" by its originators, was used as an anesthetic more than 100 years ago. Largely replaced by better anesthetics, it is now utilized rather extensively in industry, particularly in manufacture of rubber and some insecticides. It is an excellent solvent and is used to a considerable extent in hobby-craft in occupational therapy (in the uniting of pieces of plastic), particularly in hospitals for the treatment of mental illness.

A review of literature on this subject reveals a number of articles[1] on the effects of ethylene chloride and dichloride when contact occurs on living tissues. Corneal lesions are most frequently reported as resulting from inhalation by animals, though in further research with animals Erdmann[2] found lesions of the cornea following subcutaneous injection of ethylene chloride, and Kistler and Luckhardt[3] found corneal lesions following inser-

tion of ethylene dichloride by stomach tube. This would seem to indicate that the production of corneal lesions does not entirely depend upon direct contact of the vapor upon the eyes. Careful search of both foreign and domestic literature has revealed comparatively few cases of ingestion of ethylene dichloride by human beings. Most of these resulted in death.

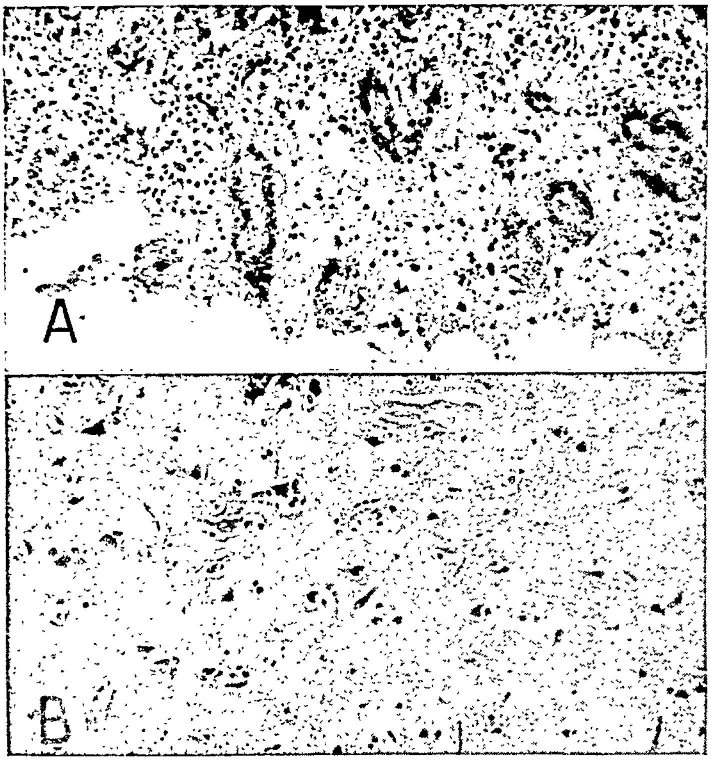

Fig. 3.—*A*, hemorrhage in gastric mucosa (hematoxylin and eosin, × 145). *B*, early toxic encephalopathy of the cerebral cortex, with prominent satellitosis (hematoxylin and eosin, × 145).

REPORT OF A CASE

At this hospital ethylene dichloride is used in occupational therapy as a part of treatment for patients with mental illness. We had the unfortunate experience of having a patient impulsively pick up a small container of ethylene dichloride and quickly swallow some of it, evidently thinking (as was true in certain other reported cases[4]) that the substance was an alcoholic drink. He was seen promptly by a physician who, judging by his story and the lack of signs of oral irritation and lack of odor on the patient's breath, concluded that nothing had been swallowed. The physician therefore at first administered no treatment. One hour and 45 minutes later the patient became violently ill, fell to the floor, and was found to be in severe shock, with cyanosis, pulmonary edema, and light coma. Positive pressure oxygen was administered with temporary prompt improvement of the patient, including lessening of the pulmonary edema and disappearance of the cyanosis. Gastric lavage was performed. For the next 12 hours the patient had intermittent vomiting and diarrhea, had lowered blood pressure, and developed severe albuminuria. Supportive measures were given, including the use of oxygen, blood transfusions, intravenously given glucose, ephedrine, cortisone, desoxycorticosterone, and adrenal cortical extract. In spite of treatment, the patient's condition continued to become worse, and he died 18 hours and 45 minutes after ingesting the ethylene dichloride.

Gross findings at autopsy included a high degree of cyanosis of all fingernails. The brain weighed 1,735 gm. There were edema and swelling with "pressure cone" markings and congestion of intracranial vessels. The left and right lungs weighed 540 and 500 gm. respectively. All but the anterior borders of the lungs were less than normally crepitant, and the cut surfaces of these areas were dark reddish-purple in color and exuded frothy reddish fluid. Such surfaces also revealed many small areas of dark red hemorrhage 2 mm. to 1 cm. in diameter. There were many petechial hemorrhages on the anterior surface of and on the left and right borders of the heart. Similar hemorrhages were present in the remainder of the external aspect of the heart, although less marked in degree than in the specifically mentioned areas. There were also a few petechial hemorrhages on the papillary muscles of the left ventricle. The spleen appeared normal except that the cut surface was darker than usual. Both the medulla and cortex of each kidney were also darker than usual. There were a few small petechial hemorrhages of the bladder serosa on its anterosuperior aspect, and the bladder mucosa was largely destroyed. The entire gastrointestinal tract, particularly the small intestine, was dark and cyanotic in appearance. There were many petechial hemorrhages in the mucosa of the stomach and entire small intestine; none were seen in the large intestine. The stomach was greatly enlarged and its contents largely gas.

Microscopically, the lungs showed scattered patches of hemorrhage and extreme vascular engorgement. In some areas the capillaries contained many leukocytes, mononuclear cells, and a fair number of large multinuclear cells resembling megakaryocytes. Many of the alveolar spaces were collapsed, and these in some areas showed abundant proteinaceous deposits (fig. 1*A*). The heart presented widespread interstitial edema, with prominence of interstitial nuclei. Cardiac vessels contained increased numbers of leukocytes; some were engorged with erythrocytes. The spleen showed congestion of the red pulp and a few patches of hemorrhage. The liver cells presented diffuse fine fatty vascuolation; cells about the central and sublobular veins contained larger fatty deposits (fig. 1*B*). Inflammatory cells were scattered throughout the sinusoids. Branches of the portal vein and some of the sublobular veins were engorged. There was a mild lymphocytic infiltration of some portal spaces. Both kidneys showed intense hyperemia throughout. The glomerular tufts presented

an apparent increase of nuclei and a tendency toward thickening of the axial portions of the basement membrane. There were swelling and sloughing of the capsular epithelium. Proteinaceous fluid was precipitated in the capsular spaces. Tubular changes were more prominent than glomerular. The proximal convoluted epithelium was severely vacuolated, markedly swollen, and badly frayed. The epithelium of distal segments showed extensive degenerative changes, including pyknosis and sloughing. Scattered casts were present, including pigmented, hyaline, and granular varieties. In one area, the distal epithelium was dotted with dull, faintly greenish pigment granules, presumably bile (fig. 2). The bladder epithelium was almost totally lost. There was generalized submucosal hyperemia. Some small patches of fresh hemorrhage were noted in the perimuscular connective tissue. The mucosal surface of the stomach was dotted with small patches of hemorrhage, and portions of the surface epithelium were missing (fig. 3*A*). The brain showed increased oligodendroglia about the neurons in the cortex (satellitosis) (fig. 3*B*).

COMMENT

It has been noted by Hueper and Smith,[4a] Roubal,[4b] Ienistea and Mezincescu,[4c] Bloch,[5] Meurs,[6] and Keyser [7] that ingestion of ethylene dichloride has produced somewhat similar changes in each instance. These are some or all of the following changes: physical collapse, pulmonary congestion or edema, pneumonia, evidences of kidney damage, coma, and death. Lochhead and Close,[8] in addition to other results, found hyperemia of the brain and scattered perivascular pontine hemorrhages. Garrison and Leadingham [9] also found areas of perivascular hemorrhage in the brain in addition to changes in the lungs, spleen, pancreas, gastrointestinal tract, and liver. In contrast to these results from ingestion of the substances, von Wendel [10] found hemorrhagic cystitis, hemorrhagic tracheobronchitis, and pneumonia after contact with the vapor through the skin and lungs. In animal experimentation, Kistler and Luckhardt [3] found changes that took place after the intravenous injection and insertion of ethylene dichloride into the stomach by tube rather similar to those found in people by other observers. They found corneal cloudiness in one dog given the substance by stomach tube. Highman, Heppel, and Lamprey,[11] working with rats, noted a high evidence of fatty changes in the heart, liver, and kidneys following subcutaneous injection of 1 cc. of ethylene dichloride per kilogram of weight, with a 35% mortality in 24 hours. These workers found the mortality rate and incidence of fatty changes mentioned to be reduced by the immediate administration of methionine and certain other sulfhydryl compounds, such as dimercaprol (BAL) and cysteine. They gave most of these by stomach tube in aqueous solution or 5% suspension of acacia in isotonic sodium chloride solution, though the methionine was given intraperitoneally in 2% aqueous solution and the dimercaprol was given intramuscularly in two divided doses four hours apart, after being dissolved in 10% benzyl benzoate in peanut oil. A noteworthy fact in this respect is that the protective substances were given after the injection of the ethylene dichloride.

Other studies by Heppel and others have been made of the toxic effects of ethylene dichloride upon living organisms. One of these [12] has shown that methionine, *p*-aminobenzoic acid, aniline, and sulfanilamide administered orally to mice before exposure to the vapor gave definite protection from the deleterious effects of the substance. Another study [13] showed that the sulfur-containing amino acids, L-cystine and DL-methionine, protected young rats against death from inhalation exposures to ethylene dichloride. Nine sulfur-free amino acids were found to be nonprotective, while some inorganic sulfur-containing compounds did not give protection. All substances found to be protective contain the sulfhydryl group. In another study,[14] it was found that in rats prepared with rations high in fat and low in protein, the mortality after inhalation exposures to ethylene dichloride was increased, while with low fat and high protein intake prior to exposure the death rate was definitely lowered.

CONCLUSIONS

In our opinion, these results suggest methods of therapy in cases of persons who have swallowed ethylene dichloride by accident or with suicidal intent. The giving of methionine, cysteine, or other sulfhydryl compounds appears to be helpful, particularly if it is done promptly after ingestion of the ethylene dichloride. Prompt gastric lavages, high colonic irrigations, intravenous administration of glucose, and blood transfusions are indicated. Other supportive measures, such as positive pressure oxygen, warmth, and stimulants, should be given when necessary. Prevention, of course, is always better than cure, and this may be obtained, as we have subsequently done here, by keeping the ethylene dichloride in a small container so surrounded by basic materials that it can not be picked up and the contents ingested (fig. 4). The container is a small bottle, larger at the bottom than at the top, which just protrudes through a hole in the surrounding wooden block. The block has a hole entirely through it that is also larger at the bottom than at the top to permit the presence of the container. As shown in figure 4, the block is held to the desk by two metal screws. The patient, therefore, can obtain ethylene dichloride only in the small amount held in a medicine dropper or adherent to the surface of the glass rod sometimes used as an applicator.

AMERICAN TRYPANOSOMIASIS (CHAGAS' DISEASE)

FIRST INDIGENOUS CASE IN THE UNITED STATES

Norman C. Woody, M.D.
and
Hannah B. Woody, M.D., Corpus Christi, Texas

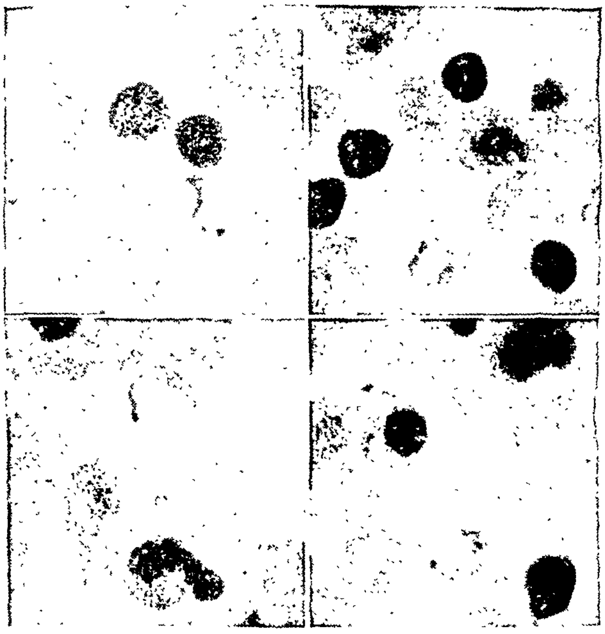
American trypanosomiasis (Chagas' disease)—the infection of man with Trypanosoma cruzi—was first described in 1909 by Carlos Chagas when he found the organism in the blood of a Brazilian child. This trypanosome had been discovered previously by him in the intestine of a triatomid bug, and he later traced the life cycle of the parasite from animal reservoir hosts, via the triatomid, to man. In subsequent years many investigators have added information on the distribution of the parasite (in animals and insects) through various parts of North and South America. In the course of these studies, naturally infected triatomids were found in California and Arizona. Similarly infected insects were found in Texas.[1] In Texas, armadillos, opossums, mice, and wood rats have been shown to be naturally infected.[2] Despite this association of a natural animal reservoir and infected insect vectors, no instance of the infection in man has been reported as occurring within the United States. The first such case is reported below.

REPORT OF A CASE

A 10-month-old white female child was seen on July 28, 1955, with the complaint of fever and listlessness of 36 hours' duration. The child was born on Oct. 5, 1954, and has been under our care since birth. The mother was well in all respects throughout pregnancy, and delivery was normal and at term. There have been no illnesses prior to the onset of the present symptoms. The mother and father were born and have lived continually in the United States, and the child has not been out of the state, having resided at the same address since birth. The home is in a newer subdivision of the city, on the edge of what had long been range land, heavily overgrown with mesquite and brush. Many opossums have been seen in the area at night. Some time before the child's illness the carcass of a dead opossum was seen being fed upon by triatomid bugs. These insects, locally called blood-suckers, have been a source of trouble in the family home for several months, often biting the occupants during sleep. The control of the bugs, according to the father, has been difficult, since the insects feed at night and scurry rapidly from sight when a light is made. The father has been bitten several times on the arms, the bites producing indurated swellings of 5 to 8 cm. in diameter. The child is not known to have been bitten; no similar swellings suggestive of bites have been found upon her.

At the time of examination the child had been having fever with a temperature of 101 to 103 F for 36 hours and was listless and irritable. She did not appear particularly ill, however, and physical examination revealed nothing but irritability. A blood cell count showed 10,600 white blood cells per cubic millimeter, of which 78% were lymphocytes. A catheterized urine specimen was negative. The following day she had a temperature of 101 F with no change in findings. On the third day of illness a fine macular rash was noted over the extremities and trunk. A tentative diagnosis of virus infection of unknown type (possibly infectious mononucleosis) was made, and the child was empirically given tetracycline (Achromycin) while we awaited developments.

The mother did not report back until Aug. 8, 1955, relating that during the 10 day interval the child had had some slight fever, that irritability had persisted, and that slight puffiness of the eyelids had developed. Rectal temperature was 102 F, and there was a moderately enlarged posterior auricular node, which was firm, nontender, and freely movable, slight periorbital edema without conjunctivitis, but no other findings. The liver was not enlarged, the spleen was not palpable, and the heart seemed normal. Hemoglobin was 11.5 gm. per 100 cc. (Sahli), white blood cells were 35,300 per cubic millimeter with 18% polymorphonuclear cells and 82% immature lymphocytes. Platelets were abundant. Many Gumprecht's shadows were present on the smear. With such findings, leukemia was suspected and a more detailed study of the smear was undertaken. In the course of examining the smears several typical examples of T. cruzi were observed (see figure). Thick film preparations yielded numerous trypanosomes, and they were noted in wet film preparations as frenetically motile animalculae. The accuracy of the identification was confirmed by Dr. John F. Pilcher, pathologist, of Corpus Christi, who also made the photomicrographs. Further confirmation was obtained from material submitted to Dr. Rodney Jung of the Department of Tropical Medicine, Tulane University School of Medicine, New Orleans.



Photomicrographs showing typical examples of Trypanosoma cruzi in blood of patient with American trypanosomiasis.

The subsequent clinical course of the patient has been somewhat anticlimactic. In view of the report of Porter,[3] based on animal studies, tetracycline therapy was resumed, and the child became afebrile within 48 hours. Slight periorbital edema has persisted. Some irritability remains. While daily checks of the blood continue to show trypanosomes, no hepatosplenomegaly, lymphadenopathy, or neurological or cardiac abnormalities have developed. Electrocardiograms have been normal, as have cardiac roentgenograms.

COMMENT

According to Craig and Faust,[4] "Trypanosoma cruzi lives in the blood as a morphologically typical trypanosome, in the reticulo-endothelial cells of man and certain animals as a leishmania, and in the intestinal tract of certain insects typically as a crithidia. In man the most frequent locations of the parasite are in the reticuloendothelial cells of the spleen, liver, lymph-nodes, and the lymphatic tissues and in the cells of the heart muscle. In addition, the cells of striated muscle, the bone marrow, the supra-renal gland, testes, ovaries and nervous system may be invaded." The pathology consists essentially of destruction of tissue cells resulting from growth and multiplication of the organism within them; clinical manifestations result from such destruction. The predominant lesions are found in heart muscle, in reticuloendothelial structures, and in the nervous system.

[4] Craig, C. F., and Faust, E. C.: Clinical Parasitology, ed. 4, Philadelphia, Lea & Febiger, 1945.

Two forms of American trypanosomiasis are commonly described. The acute form, usually seen in young children, is generally pictured as lasting from 20 to 30 days and is characterized by fever, lymphocytosis, with or without a leukocytosis, nonpitting edema of the lids and face (occasionally the entire body), due presumably to deposition of a mucoid material in the tissues, and neurological symptoms ranging from simple irritability to those typical of encephalitis. Trypanosomes are demonstrable in the blood during the acute form. The chronic form succeeds the acute stage in most children who survive. It is seen also in adults, and symptoms are dependent on localization of the parasites within the tissues. Consequently, cardiac, adrenal, and neurotropic forms have been described. Except for periods of febrile exacerbations, the trypanosomes cannot be found in the blood in the chronic form, diagnosis being possible by use of complement fixation or skin tests. Xenodiagnosis, consisting of allowing laboratory-bred triatomids to feed on a suspected individual and the subsequent demonstration of the parasite in the intestinal tract of the bug, is an interesting method. The trypanosome is said to grow well on N. N. N. medium. Animal inoculation, using guinea pigs, hamsters, rats, mice, puppies, and kittens, is a practical method of recovering the organism.

SUMMARY AND CONCLUSIONS

The present case proves that strains of Trypanosoma cruzi, naturally occurring in animals and reduviid bugs in the vicinity of Corpus Christi, Texas, are infective for man; it implies that unrecognized cases are probably present in the area; and it emphasizes that acute American trypanosomiasis (Chagas' disease) is encountered in young children. The existence of unsuspected human carriers becomes an immediate possibility that will have to be reckoned with in the administration of blood transfusions. Kelser,[4a] working in Panama, showed by means of complement fixation tests an incidence of 3.7% of unsuspected infection from a group of 1,626 persons. Murgatroyd [5] recommends that persons from an endemic area not be used as blood donors unless they give negative complement fixation tests. T. cruzi has remained viable in blood from acute cases as long as 257 days.[6]

This patient is being reported in order to alert physicians in the southwestern United States to the possibility of encountering American trypanosomiasis in man in these areas. The vague clinical manifestations in this patient suggest that, for children living in areas where animal reservoirs and infected insects are known to exist, the diagnosis of trypanosomiasis should be considered whenever vague febrile illnesses are accompanied by findings suggestive of myocarditis or encephalitis or whenever they are associated with degrees of lymphocytosis reminiscent of infectious mononucleosis, infectious lymphocytosis, or leukemia. Strain differences of T. cruzi apparently account for observed variations of virulence and for organ predeliction. Such characteristics of the trypanosomes isolated from this child are, of course, as yet unknown. We have begun studies to illuminate these points, to be reported at a later date.

CARBON DISULFIDE POISONING

REPORT OF TWO CASES

Morris Kleinfeld, M.D.
and
Irving R. Tabershaw, M.D., New York

In spite of the scarcity of reports on carbon disulfide poisoning in the American literature as contrasted with the European literature, cases of this condition do occur in the United States. The apparently low incidence may be due to lesser use of this material or to better engineering control methods. The most cogent reason, however, is the probable unfamiliarity with this disease on the part of the general practitioner. Two recent cases of carbon disulfide poisoning are presented for the following reasons: (1) the clinical manifestations and differential diagnoses are sufficiently interesting and bizarre to warrant description and comment, and (2) the relationship between maximum allowable concentrations and the occurrence of carbon disulfide poisoning needs reevaluation.

REPORT OF CASES

CASE 1.—A 43-year-old male had as his chief complaint anorexia and marked paresthesias of his hands and numbness of his legs. The patient dated his present difficulties to an accident that occurred in his place of employment when he was suddenly exposed to an excessive amount of carbon disulfide while attempting to repair a leaky line. Although he felt groggy and weak, he continued to work until late that evening. Returning home, he slept 15 hours and, upon awakening, complained of severe headache and marked weakness. Shortly thereafter, he became more listless and lethargic and two days later was hospitalized.

On admission to the hospital, the patient was found to be markedly dehydrated and pale, with no abnormal clinical findings in his chest and abdomen. No pathological reflexes were elicited. There were several hemorrhagic areas in both fundi. There was a slightly elevated temperature. Blood pressure was 100/70 mm. Hg. Laboratory examination revealed a moderately severe anemia; hemoglobin level was 5.0 gm. per 100 cc.; red blood cell count was 2,300,000 per cubic millimeter; hematocrit 17%. The white blood cell count was moderately elevated (22,400 per cubic millimeter). The reticulocytes count was 1.5%. The bone marrow showed a low ratio of erythroid elements. Chest x-ray taken nine days after admission showed a broncho-

---

Director (Dr. Tabershaw) and Chief, Medical Unit (Dr. Kleinfeld), Division of Industrial Hygiene, New York State Department of Labor.

Dr. S. E. Krohn, Utica, N. Y., and Dr. T. W. Piekielniak, Whitesboro, N. Y., gave permission to publish the case histories of their patients.

pneumonia of the lower lobe of the right lung. Stool examination for occult blood was negative, but a gastrointestinal series revealed the presence of a large gastric ulcer of the lesser curvature.

The patient was treated with antibiotics, blood transfusions, and small amounts of corticotropin (ACTH). He showed gradual improvement and became more alert, and his strength increased. His temperature returned to normal and persisted so until discharge. Repeat blood cell counts showed a hemoglobin level of 10.6 gm. per 100 cc.; hematocrit 36%; and a white blood cell count of 11,900 per cubic millimeter with a normal differential count. A bone marrow smear two weeks after admission revealed a normal erythroid-myeloid ratio. The chest x-ray two days prior to discharge showed clearing of the pneumonic process, and he left the hospital on the 16th hospital day. Since discharged, the patient has not been up to par. He has had periods of depression, showing a lack of interest in his surroundings, sexual impotency, and paresthesias in the arms and hands. There are no abnormal neurological reflexes. Funduscopic examination shows no evidence of hemorrhage. He is presently receiving thiamine injections and vitamin B_{12}.

History.—About 10 years ago the patient began to complain of headaches, general weakness, nausea, and inability to concentrate. These were transient and would subside after he would leave the plant. Six years ago he began to have recurrent epigastric pain, and a gastrointestinal series showed an obstructing duodenal ulcer. Three years ago he left his present employment for several months because of weight loss, weakness, and malaise. These symptoms cleared up and he returned to work. During the past year, the above symptoms recurred, and he attributed this to an increase in the work-load. A three day rest period from work was insufficient to clear up his symptoms.

Environmental History.—For the past 20 years, the patient has worked in a churn room of a rayon factory. During most of this period he was a churn operator, which involved the loading of cellulose material into and the subsequent cleaning of churns. Carbon disulfide is pumped into a closed overhead weighing tank from which it is supplied to each churn as needed. In the transferring and shoveling operations and in the cleaning of the churn, the workers are brought into close contact with the carbon disulfide vapors from the material.

CASE 2.—A 49-year-old male complained of numbness of hands, difficulty in walking, unsteadiness, double vision, loss of libido, impotency, temper outbursts, and depression. The patient asserted that his ailment first started about 10 years ago with intermittent numbness of the hands and subsequent impairment of his ability to do skilled movements in writing. These symptoms were transient, and the patient continued to work. About eight years ago he began to demonstrate emotional instability and forgetfulness. At the same time, he complained of loss of libido and sexual impotency. He also experienced easy fatigability and giddy sensations. These symptoms became increasingly more severe, and about four years ago his sexual impotency was complete. For the past four years he has exhibited marked depression, difficulty in concentration, and memory impairment. Three years ago, while at work, he had a sudden episode of diplopia and unsteadiness of gait that lasted about 12 hours. This unsteadiness of his gait persisted. Two years ago his diplopia, which still persists, returned. Hernia repair was done three years ago. He was hospitalized several times during the past few years for episodes of mental depression. The last hospitalization occurred one year ago, and a recent attempt to rehabilitate him at a special clinic proved unsuccessful.

Clinically, the patient was well developed and well nourished but appeared depressed and apprehensive. There was no cough, dyspnea, or cyanosis. The pupils were equal and regular and reacted to light and accommodation. There was lateral and vertical nystagmus of the left eye and paralysis of the left lateral rectus muscle. Examination of the chest and abdomen revealed no abnormalities. Examination of extremities revealed bilateral varicosities. Neurological examination showed considerable unsteadiness of gait. There was marked unsteadiness of the right hand. Deep reflexes were hyperactive. Sensation was normal. Vibratory and position sense were intact. Alternating movements of the left leg were impaired. Funduscopic examination revealed "crumb-like" exudates in upper temporal quadrant of right retina.

Laboratory examination showed that the red blood cell count, hemoglobin level, and white blood cell count and differential were within normal limits. The urinalysis was normal. The Mazzini test was negative. Chest x-ray revealed a slight left ventricular prominence with essentially normal lung fields. The only pertinent finding on the electrocardiogram was a tendency toward low amplitude of the Q, R, and S complexes; there was left deviation of the electrical axis. The patient has been treated by intensive therapy with vitamin B complex, thiamine, and androgens but has shown very little improvement.

Environmental History.—The operations performed on this patient and his exposure to carbon disulfide were essentially the same as those of the patient described in case 1.

COMMENT

These cases illustrate the widespread systemic manifestations that may follow exposure to carbon disulfide. Of particular significance are the irreversible neuropsychiatric and organic changes that can follow prolonged exposure to this agent. This is well exemplified in case 2. Although many authors feel that the clinical picture is usually reversible even after long exposure, it is important to recognize that cases do occur that are refractory to all forms of therapy.[1] This makes it all the more essential to recognize the symptom complex early, before the toxic agent leaves its telltale effect. Both patients showed symptoms that may be mistaken for neuralgia and neurasthenia of nonspecific origin and that can persist for many years before their relationship to the patient's environment is discovered. Not infrequently, it takes a sudden acute exposure to carbon disulfide to focus attention on the existence of chronic symptoms. This is seen in case 1.

The patient in case 1 revealed, in addition to the neuropsychiatric manifestations, severe organic changes that were concomitant. It is noteworthy that this individual had gastrointestinal symptoms that were diagnosed as a gastric ulcer by x-ray. The lesion healed after removal of the patient from his environmental exposure, yet no causal relationship was entertained. That carbon disulfide may produce gastrointestinal ulceration is suggested by the study reported by Weise, who analyzed the gastrointestinal symptoms in 100 workers in the rubber and artificial silk industries.[2] In 14 of these cases, ulcer of the stomach or the duodenum was diagnosed and operations were performed on several patients. In 11 others, ulcers were suspected. The morbidity statistics from several large artificial silk factories indicate an incidence of stomach trouble of 17.7% from exposure to carbon disulfide, while all other textile factories show 2.7%. Vigliani reported 150 cases of carbon disulfide toxicity, in 28 of which gastric disturbance, notably gastric pain, was prominent.[3]

The marked anemia of the patient in case 1 observed on his last admission may have been due to the duodenal ulcer, in spite of the negative stools for occult blood. A direct effect of carbon disulfide on the bone marrow cannot, however, be ruled out. What is most significant

2. Weise, W.: Gastro-Intestinal Disturbances Caused by Chronic Inhalation of Carbon Disulfide and Hydrogen Sulfide, Arch. f. Gewerbepath. u. Gewerbehyg. **4**: 219, 1933.
3. Vigliani, E. C.: Clinical Observations on Carbon Disulfide Intoxication in Italy, Indust. Med. **19**: 240, 1950.

is the rapid healing of the ulcer after removal from his environmental exposure. How carbon disulfide produces an ulcer is speculative. There are several mechanisms that may be responsible: a direct effect on the gastric cell, increased vagal effect, or increased corticotropic activity. In retrospect, it would appear that the gastric ulcer the patient had five years ago, as well as the present duodenal ulcer, may be causally related to the carbon disulfide intoxication. The essential role played by a good occupational history in the diagnosis of this disorder is obvious. The very nature of the nonspecificity of the early symptoms resulting from low-grade exposure and the subsequent widespread systemic manifestations that may ensue make differential diagnosis difficult. Patients are often incorrectly thought to be suffering from chronic alcoholism, lead poisoning, brain tumor, multiple sclerosis, and polyneuritis of other origin.[4] Also, in view of the absence of any known specific antidote against carbon disulfide poisoning, the most effective therapy for this disorder is the early recognition and removal of the patient from exposure.

The ideal goal to be sought is prevention, and this necessitates both medical and engineering control. The physician's familiarity with the patient's occupation and the exact nature of his operations will aid immeasurably in the total evaluation of the patient's complaints and clinical findings. Environmental control involves essentially effective ventilation to maintain the air concentration of carbon disulfide vapor at safe levels. This has been established as 20 ppm by the American Standards Association, principally on the basis of clinical experience and engineering feasibility. This standard has not received universal agreement. It is noteworthy that Lewy, evaluating the medical aspects of carbon disulfide toxicity in Pennsylvania, suggested 10 ppm as a safe limit for short-term exposures.[5] Recently, Graziani and Pecora reported that 17 workers exposed to concentrations of approximately 2 to 4 ppm revealed a diminution in cholinesterase in the blood and abnormal electrocardiographic changes showing slight toxic reaction to carbon disulfide.[6] Our own investigation of the work area of the cases described above revealed a weighted average slightly in excess of 20 ppm. It is significant that 14 additional employees (employed less than five years) in this same work area complained of occasional nausea and headache but presented no overt evidence of poisonings. The findings of other investigators[7] and our own data suggest the need for reducing the present maximum allowable standard, preferably to 10 ppm. The improved engineering techniques now available make this feasible and will give workers a greater safety factor in handling this material.

SUMMARY AND CONCLUSIONS

In two cases of chronic carbon disulfide poisoning presented, these significant aspects were noted. 1. In one patient the diagnosis was not entertained for about five years; in the other, an acute, overwhelming exposure made the picture of chronic poisoning nonequivocal. 2. The possible causal relationship between chronic carbon disulfide exposure and peptic ulceration was entertained. 3. The neuropsychiatric manifestation in both patients predominated. Widespread systemic manifestations were also present. 4. In one patient, the severe organ system damage was irreversible. In view of the experiences of others and our own data after reevaluation of the relationship between maximum allowable air concentration of carbon disulfide and occurrence of poisoning, it is recommended that the present standard of 20 ppm be reduced to 10 ppm to provide a greater safety factor in handling this material.

COUNCIL ON PHARMACY AND CHEMISTRY

NEW AND NONOFFICIAL REMEDIES

Monographs and supplemental statements on drugs that appear in this column have been authorized by the Council for publication and inclusion in New and Nonofficial Remedies. They are based upon the evaluation of available scientific data and reports of investigations.

R. T. STORMONT, M.D., *Secretary.*

Sodium Radio-Iodide (I^{131}), U. S. P.—Sodium radio-iodide is a salt in which the iodine is present as the radioactive isotope, iodine-131. It is obtained from the products of uranium fission, is essentially "carrier-free," and contains only trace amounts of the naturally occurring isotope iodine-127.

The preparation of this compound that is listed in the U. S. P. is Sodium Radio-Iodide (I^{131}) Solution.

Actions and Uses.—Sodium radio-iodide (I^{131}) is freshly prepared from the radioactive isotope, I^{131}. It is useful for diagnostic studies in patients with suspected thyroid disease, for treatment of selected cases of thyrotoxicosis, and, in conjunction with other agents and methods, for the palliative treatment of carcinoma of the thyroid gland and metastatic lesions arising from it. It is also used to detect distant metastatic growths of thyroid carcinoma and to determine whether intact tissue or a tumor mass is of thyroid origin. It may be used to induce hypothyroidism in euthyroid patients with angina pectoris to aid in the management of that condition.

The accumulation of radio-iodine in the thyroid gland probably reflects, to a large extent, the formation of diiodotyrosine and thyroxine and the storage of these compounds in the thyroid follicle. At first, iodine may be present in the inorganic form (NaI), but in a short time it becomes protein-bound, apparently linked with the tyrosine radical, in the gland. Patients who have little or no functioning thyroid tissue, particularly with the clinical syndrome of myxedema, usually excrete considerably more of the diagnostic dose in the urine during the first 24 to 72 hours than do normal subjects. The uptake of radio-iodine may be depressed by prior intake of stable iodine in any form or by the use of thyroid substance or of antithyroid drugs. Among the many iodine-containing preparations and compounds that may contain dissociable iodine are:

1. External iodine preparations:
    a. Ointments and solutions of iodine or iodides
    b. Tinctures of iodine or iodides
    c. Iodoform gauze
2. Internal iodine preparations:
    a. Strong iodine solution (compound iodine solution, Lugol's solution)
    b. Potassium iodide and potassium iodide solution
3. Asthma, cough, and vitamin preparations containing iodine compounds
4. X-ray contrast mediums:
    a. Gallbladder mediums, such as tetraiodophenolphthalein, iodoalphionic acid, iodopanoic acid, and iophenoxic acid
    b. Urographic and vasographic mediums, such as sodium iodide, iodopyracet, sodium acetrizoate, and sodium iodomethamate
    c. Myelographic mediums, of both the oily and the aqueous type, containing iodine
    d. Cavity and sinus visualization mediums, such as sodium iodide and chloriodized and iodized oils
5. Antiparasitic drugs:
    a. Iodochlorhydroxyquin
    b. Diiodohydroxyquin
6. Thyroid extract, thyroxine
7. Iodinated antithyroid drugs, such as iothiouracil sodium

Other antithyroid drugs, particularly those of the thiourea series and methimazole, also influence the uptake of radio-iodine by thyroid tissue. The quantitative uptake of radio-iodine by malignant tumors of the thyroid varies in accordance with many factors, including their histological differentiation.

Side-effects depend upon radiation dosage range. None are to be expected with the doses used for diagnostic tests (1 to 100 μc [microcuries]). With the therapeutic dose used in treatment of hyperthyroidism (5 to 20 mc. [millicuries]), there may be a mild febrile reaction, with a slight decrease in blood leukocytes that returns rapidly to normal and a slight increase in sedimentation of erythrocytes. Local radiation effects (swelling and soreness) may be observed in the neck, and thyroid storm or crisis may be induced in very toxic cases. With doses administered in thyroid cancer (30 to 100 mc.), systemic radiation effects may be encountered, such as depression of hematopoiesis, as well as local radiation effects upon sites near functioning thyroid tissue. As with other agents that influence the thyroid, some direct influence on exophthalmus may be observed. Hypothyroidism is also a possible side-effect. Sodium radio-iodide is generally contraindicated in the presence of pregnancy.

Dosage.—Sodium radio-iodide is administered orally or intravenously in aqueous solutions of appropriate concentration. It is administered orally also in the form of capsules, to the inner surface of which an exact amount of the radioisotope is fixed. It should be emphasized that there is always a difference between the dosage administered and the amount taken up by the gland and that dosage is subject to variation in accordance with the age and condition of the patient. As a diagnostic agent for tracer and uptake studies, the dosage ranges from 1 to 50 μc. For diagnostic studies of aberrant thyroid tissue, outline scanning of the thyroid, and localization of metastases, the tracer dose may be as much as 100 μc or more.

The therapeutic dose is usually calculated after a diagnostic test to determine the percentage absorbed by the gland in a specified time, such as 24 hours. For the treatment of thyrotoxicosis, a single or fractional dose procedure may be used. With an estimated uptake of about 70%, a single dose administered is usually 105 to 180 μc per estimated gram of thyroid tissue, so as to provide a retained dose of about 75 to 125 mc. Accurate estimate of the amount of thyroid tissue may be difficult and should be considered carefully to avoid error in the calculation of dosage. In the majority of patients, the total therapeutic single dose should not exceed 8 mc. Any further dosage usually is not considered before 6 months has elapsed. If the fractional method of dosage is used, the initial dose is considerably less and the usual interval between doses is about 6 weeks to 2 months.

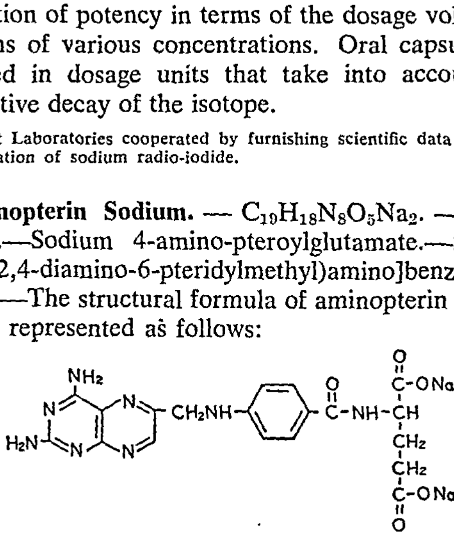
To induce hypothyroidism in the management of euthyroid angina pectoris, the isotope is administered orally either as a single dose of about 20 mc. or weekly in doses of about 6 mc. each for 5 weeks. After either method, further treatment may be given after an interval of not less than 60 days when additional antithyroid therapy is required.

Since the treatment of thyroid carcinoma and metastases is unique for each case, no information on the dosage for these conditions is included.

The decay in radioactivity of solutions, based on the half-life of the radioisotope, makes it necessary to correct the labeled potency immediately prior to use, in accordance with the time that has elapsed after the specified assay. A table of correction factors and a graphic chart are available to permit reasonably accurate recalculation of potency in terms of the dosage volume of solutions of various concentrations. Oral capsules are provided in dosage units that take into account the radioactive decay of the isotope.

Abbott Laboratories cooperated by furnishing scientific data to aid in the evaluation of sodium radio-iodide.

Aminopterin Sodium. — $C_{19}H_{18}N_8O_5Na_2$. — M.W. 484.40.—Sodium 4-amino-pteroylglutamate.—Sodium N-{*p*[(2,4-diamino-6-pteridylmethyl)amino]benzyl} glutamate.—The structural formula of aminopterin sodium may be represented as follows:



Actions and Uses.—Aminopterin sodium, a chemical derivative of folic acid, is said to "block" the action of the latter agent. In experimental animals it interferes with the conversion of folic acid to an active metabolite called citrovorum factor that is utilized for growth by the bacterial species Leuconostoc citrovorum. Aminopterin sodium depresses hematopoiesis and may exert a general toxic effect on all reticuloendothelial tissue. It is not yet clear whether its suppression of hematopoiesis is chiefly the result of folic acid antagonism or a systemic toxic action. It is thought that altered metabolism of folic acid may play a role in hematopoietic disorders characterized by excessive or disorderly proliferation of blood cells or their precursors.

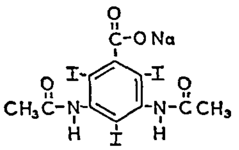
Aminopterin sodium is indicated only for the treatment of acute leukemia in children. It has produced temporary remission and appears to have increased survival time in acute leukemia of childhood for periods ranging from weeks to two years. Following therapy the hematological picture, as reflected in blood and bone marrow smears, is frequently almost indistinguishable from normal and persists for varying periods. The greatest effect has been observed in acute leukemia characterized by immature (blast) cell forms in the bone marrow or blood. Aminopterin sodium is not recommended for the treatment of leukemia in adults because it frequently produces no results. The drug has a powerful lethal action on embryonic tissue and should not be used in patients known to be, or suspected of being, pregnant.

Aminopterin sodium may produce irreversible depression of all blood cellular elements. In general, its toxicity is in direct proportion to the dose given. Constant supervision is essential. The drug should be discontinued if any of the following signs appear: ulceration of buccal mucosa, gastrointestinal ulceration and bleeding, diarrhea, rapid fall in blood leukocyte count, bone marrow depression primarily of the leukocyte series, hemorrhage at any site, or alopecia. The drug should not be prescribed without adequate facilities for repeated laboratory examination of the blood and bone marrow and clinical observation of the patient. White blood cell counts should be performed daily during the first month of therapy and three times a week thereafter; complete blood cell counts should be performed weekly and bone marrow punctures weekly to monthly. Bleeding and coagulation times and blood grouping and typing should be performed initially in anticipation of transfusion or surgery that also may be indicated.

Dosage.—Aminopterin sodium should be administered orally. For infants the dosage is 0.25 mg. and for children 0.5 mg., given three to six times weekly depending on the severity of the disease. It should be administered over a period of three weeks or more until bone marrow function becomes normal or signs of toxic reaction appear. Normal bone marrow function is considered to be indicated by a smear that reveals not more than 20% blast cells and lymphocytes. If there are toxic reactions, therapy should be stopped for 7 to 10 days; after toxic signs subside, it may be resumed at a somewhat lower dosage and continued until a clinical remission occurs and/or bone marrow returns to normal function. In the absence of a remission, and when the patient's condition remains reasonably good, therapy may be continued for two months or more at increased dosage, even to the point of mild toxicity, in an effort to obtain a remission. When the bone marrow returns to normal function, the patient may be continued on maintenance dosage, or treatment may be discontinued. If therapy is intermittent, sternal marrow aspiration should be performed every two weeks, as it is only by means of bone marrow studies that the earliest sign of relapse may be detected. Therapy then can be reinstituted before clinical deterioration appears.

Lederle Laboratories Division, American Cyanamid Company, cooperated by furnishing scientific data to aid in the evaluation of aminopterin sodium.

Diatrizoate Sodium. — $C_{11}H_8I_3N_2NaO_4$. — M.W. 635.92. — Sodium 3,5-diacetamido-2,4,6-triodobenzoate.—The structural formula of diatrizoate sodium may be represented as follows:



Actions and Uses.—Diatrizoate sodium is a water-soluble organic iodine compound suitable for use as a roentgenographic contrast medium in intravenous (excretory) urography. When injected intravenously, the agent is transported rapidly to the kidneys where it is excreted unchanged in the urine. When kidney function is normal, elimination begins almost immediately so that suitable x-ray shadows often can be obtained within 5 minutes after injection. With impaired renal function and delayed excretion, adequate shadows may not be obtainable until after 30 minutes or more. The time of appearance of suitable shadows also is influenced by the adequacy of preparation of the patient and the technique of injection.

Diatrizoate sodium should be used with the same precautions as for other organic iodine compounds and likewise is contraindicated in severe liver disorders and in advanced renal impairment with severe uremia. It should be used with caution, if at all, in patients with a history of allergy, especially those sensitive to iodine in any form, and caution also is advisable in patients with hyperthyroidism, hypertension, or active tuberculosis. Studies so far indicate that the agent produces a minimum incidence of minor side-effects and rarely produces severe vascular reactions. For the management of severe reactions, see the general statement in N. N. R. 1955 on water-soluble organic iodine compounds for roentgenography.

Dosage.—For excretory urography, diatrizoate sodium is administered by intravenous injection of a 50% solution. One cc. of this solution is used as a test dose for sensitivity. Crystals may form if the solution is cool but readily redissolve when warmed. After appropriate preliminary preparation of the patient the evening before examination and after examination of a "scout" film exposed immediately prior to injection to rule out confusing gas shadows, 30 cc. of a 50% solution, administered over a period of 1 to 3 minutes, usually is sufficient for visualization of the urinary tract on film exposed either 5, 10, or 15 minutes after injection. Compression of the bladder prior to injection may facilitate adequate filling of the pelves and ureters.

Winthrop-Stearns, Inc., cooperated by furnishing scientific data to aid in the evaluation of diatrizoate sodium.

STATUS OF SURGERY FOR ASTHMA

There have been essentially four surgical procedures recommended for the treatment of bronchial asthma. First, there is the removal of localized destroyed areas of lung plus neurectomy.[1] Next, there has been the treatment of patients proved to be essentially totally epinephrine-resistant by carrying out an upper dorsal sympathectomy, unilateral or bilateral, in order to resensitize the patient to the effect of his own circulating epinephrine. This was described in detail by Carr.[2] Pulmonary vagotomy is recommended by Rienhoff and Gay.[3] Blades [4] described a combined denervation procedure removing the pulmonary plexus incorporating excision of both sympathetic and parasympathetic pulmonary denervation.

Follow-up studies on the long-term results of surgical treatment for asthma have been generally disappointing. Long-term follow-up of postganglionic dorsal sympathectomy in the patients proved preoperatively to be distinctly epinephrine-resistant has shown satisfactory persistent response to the surgical procedure.[5] Vagotomy alone and combined denervation in the form of plexectomy have usually produced from six months to one year of beneficial results followed by a complete return of symptoms. Long-term follow-up[6] suggests surgery is useful if there is a localized destructive area of bronchiectasis with associated asthma in a patient whose attacks originated resultant to infection and whose recurrences parallel episodes of infection. Long-term cure can be expected by complete excision of the destroyed tissue plus denervation in the form of high transection of the vagus nerve just below the level of the recurrent laryngeal nerve with excision of all branches going from the recurrent laryngeal nerve to the involved bronchial tree.[6] In a patient in whom an entire lung is destroyed and function tests show essentially no oxygen uptake by this organ, total pneumonectomy without associated denervation has produced permanent cure.

The basic principle involved in the present status of surgery for asthma is that denervated muscle can still present severe degrees of contraction in response to the appropriate allergen after denervation. Therefore, denervation procedures must be accompanied by total removal of the offending allergen, whether it be intrinsic or extrinsic. The situation of complete epinephrine resistance is seldom seen in bronchial asthma but, when present, should bring up serious consideration of the approach outlined by Carr; namely, dorsal sympathectomy. Unless epinephrine resistance is shown to be present in these patients, the sympathetic nervous system to the lung should not be tampered with.[7] Complete pulmonary vagotomy releases the bronchopulmonary tree from bronchospasm of neurogenic origin. Permanent complete vagotomy to the lung is not obtained by resection of the pulmonary plexus and requires complete transection of the vagus nerve by the method described above. The surgical treatment of bronchial asthma should only be considered as a last resort, except in persons with an obvious origin of asthma in response to bronchopulmonary infection. Demonstrable localized destroyed areas of the bronchopulmonary tree may act as trigger mechanisms.[8] It is advisable that all patients with bronchial asthma be considered for bronchoscopy to rule out bronchial ulcer as a cause for their disease as well as to eliminate such possibilities as neoplasms and stricture, which can produce wheezing.

DROWNING

Throughout most of the world drowning is a problem with which the public and the medical profession must cope. Warnings are issued to swimmers, waders, campers, fishermen, and others, but this does not prevent death from occurring frequently. Many studies have been made of artificial respiration but comparatively few of the physiology of drowning. As has been pointed out elsewhere,[1] this is important until more is learned about this method of dying. Until then the most important act is the immediate initiation and unceasing continuation of artificial respiration. Other procedures are secondary and should be implemented only as they can without interference with the artificial respiration. While the airway must be watched, any elaborate or unnecessary procedures will lessen the chance of survival. In view of the stimulus given to underwater swimming during and since World War II, it is hoped that research on drowning will be conducted extensively and the reports published without delay. There are few things in life that offer more attraction and at the same time more danger than bodies of water. Young and old, experienced swimmer and nonswimmer, in fact all, are likely subjects for drowning—and the water does not have to be deep.

ORGANIZATION SECTION

ANNUAL A. M. A. MEETING IN CHICAGO JUNE 11-15, 1956

The Annual Meeting of the American Medical Association will be held in Chicago, June 11-15, 1956, with a complete program of lectures, television, motion pictures, and scientific exhibits. The lecture program for each section is prepared by the section secretary, and prospective participants should communicate as soon as possible with the secretary of the section before which they hope to read a paper.

Application blanks for space in the Scientific Exhibit are now available. Applications for space close on Jan. 9, 1956, but early application is encouraged. Blanks may be obtained from section representatives to the Scientific Exhibit or from the Secretary, Council on Scientific Assembly, American Medical Association, 535 N. Dearborn St., Chicago 10, Ill.

Following are the secretaries and representatives to the Scientific Exhibit from the various sections:

Anesthesiology

Secretary—Daniel C. Moore, M.D., 1118 Ninth Ave., Seattle 1.

Exhibit Representative—Scott M. Smith, M.D., 910 Medical Arts Bldg., Salt Lake City 1.

Dermatology

Secretary—Clarence S. Livingood, M.D., Henry Ford Hospital, Detroit 2.

Exhibit Representative—Samuel M. Bluefarb, M.D., 30 N. Michigan Ave., Chicago 2.

Diseases of the Chest

Secretary—John F. Briggs, M.D., 350 St. Peter St., St. Paul 2.

Exhibit Representative—Edwin R. Levine, M.D., 109 N. Wabash Ave., Chicago 2.

Experimental Medicine and Therapeutics

Secretary—George E. Burch, M.D., 1430 Tulane Ave., New Orleans 12.

Exhibit Representative—Joseph F. Ross, M.D., University of California Medical Center, Los Angeles 24.

Gastroenterology and Proctology

Secretary—Everett D. Kiefer, M.D., 605 Commonwealth Ave., Boston 15.

Exhibit Representatives—William H. Dearing, M.D., 102 Second Ave., S. W., Rochester, Minn.; Willard H. Bernhoft, M.D., 537 Delaware Ave., Buffalo 2.

General Practice

Secretary—E. I. Baumgartner, M.D., 25 Alder St., Oakland, Md.

Exhibit Representative—Charles E. McArthur, M.D., 1934 E. Fourth Ave., Olympia, Wash.

Internal Medicine

Secretary—A. Carlton Ernstene, M.D., 2020 E. 93rd St., Cleveland 6.

Exhibit Representative—Henry T. Ricketts, M.D., 950 E. 59th St., Chicago 37.

Laryngology, Otology and Rhinology

Secretary—Hugh A. Kuhn, M.D., 112 Rimbach St., Hammond, Ind.

Exhibit Representative—Walter E. Heck, M.D., Stanford University Hospitals, San Francisco 15.

Military Medicine

Secretary—Capt. Cecil L. Andrews, M.C., U.S.N., Bureau of Medicine and Surgery, Department of the Navy, Washington 25, D. C.

Exhibit Representative—Capt. Robert V. Schultz, M.C., U.S.N., Bureau of Medicine and Surgery, Department of the Navy, Washington 25, D. C.

Nervous and Mental Diseases

Secretary—Karl O. Von Hagen, M.D., 2010 Wilshire Blvd., Los Angeles 57.

Exhibit Representative—G. Wilse Robinson Jr., M.D., 2625 W. Paseo, Kansas City 8, Mo.

Obstetrics and Gynecology

Secretary—D. Frank Kaltreider, M.D., University Hospital, Baltimore 1.

Exhibit Representative—Frederick H. Falls, M.D., P. O. Box 47, River Forest, Ill.

Ophthalmology

Secretary—Harold G. Scheie, M.D., 313 S. 17th St., Philadelphia 3.

Exhibit Representative—Frank W. Newell, M.D., 950 E. 59th St., Chicago 37.

Orthopedic Surgery

Secretary—Frederick R. Thompson, M.D., 16 E. 90th St., New York 28.

Exhibit Representative—J. Vernon Luck, M.D., 1930 Wilshire Blvd., Los Angeles 57.

Pathology and Physiology

Secretary—Edwin F. Hirsch, M.D., 1439 S. Michigan Ave., Chicago 5.

Exhibit Representative—Frank B. Queen, M.D., 3181 S.W. Sam Jackson Park Rd., Portland 1, Ore.

Pediatrics

Secretary—Wyman C. C. Cole Sr., M.D., 3001 W. Grand Blvd., Detroit 2.

Exhibit Representative—F. Thomas Mitchell, M.D., Le Bonheur Children's Hospital, Memphis 5, Tenn.

Physical Medicine

Secretary—Walter J. Zeiter, M.D., 2020 E. 93rd St., Cleveland 6.

Exhibit Representative—Donald A. Covalt, M.D., 400 E. 34th St., New York 16.

Preventive and Industrial Medicine and Public Health

Secretary—Frank Princi, M.D., University of Cincinnati College of Medicine, Cincinnati 19.

Exhibit Representative—Paul A. Davis, M.D., 633 E. Market St., Akron 4, Ohio.

Radiology

Secretary—Traian Leucutia, M.D., Harper Hospital, Detroit 1.

Exhibit Representative—Richard H. Chamberlain, M.D., 3400 Spruce St., Philadelphia 4.

Surgery, General and Abdominal

Secretary—Walter G. Maddock, M.D., 250 E. Superior St., Chicago 11.

Exhibit Representative—John H. Mulholland, M.D., 550 First Ave., New York 16.

Urology

Secretary—Thomas A. Morrissey, M.D., 40 E. 61st St., New York 21.

Exhibit Representative—Milton M. Coplan, M.D., 550 Brickell Ave., Miami 32, Fla.

JOINT COMMISSION ON ACCREDITATION OF HOSPITALS

Questions and Answers

In order to aid a better understanding of the activities of the Joint Commission on Accreditation of Hospitals, the commission has provided the following questions and answers. Physicians and others interested in having their questions answered in THE JOURNAL may send them to the Editor of THE JOURNAL for referral to the commission or direct to Dr. Kenneth B. Babcock, Director of the Commission, 660 N. Rush St., Chicago 11.

QUESTION.—*Does the Joint Commission on Accreditation of Hospitals approve of the use of "short forms" for medical records? M.D., Virginia.*

ANSWER.—Short form medical record formats are acceptable under certain circumstances. These abbreviated forms may be used for admissions of 48 hours or less when these admissions are for minor conditions. The conditions in which such forms can be utilized should be delineated in the rules and regulations of the hospital staff. As a rule, such conditions include cystoscopic examinations, dilation and curettage, simple fractures, tonsillectomies, removal of sebaceous cysts, and similar procedures. Obviously, many others may be included. It should be emphasized that any major condition, irrespective of the time of hospitalization, must have a complete and full medical record. In any instance, the information on the record must be sufficient to substantiate the diagnosis and justify the treatment. The determination of those conditions that should have had a complete record rests with the medical records committee of the staff.

QUESTION.—*We have an application for staff membership from a graduate of a medical school that was not approved at the time the applicant's degree was granted. The credentials committee believes him worthy of staff appointment, but our bylaws state the staff must be graduates of "approved" schools. What should our course be? M.D., Massachusetts.*

ANSWER.—Amend the staff bylaws. The model bylaws of the Joint Commission on Accreditation of Hospitals now state that a graduate be from an approved or recognized school of medicine with an M.D. or M.B. degree, etc. There are many worthy graduates from schools either in this country or in foreign lands who would be denied hospital privileges under the restricted wording. The word recognized implies recognition by the board of examiners of the individual state involved. An M.D. licensed by the state and eligible for membership in the local medical society is considered acceptable to the Joint Commission on Accreditation of Hospitals if the credentials committee of the hospital has evaluated him thoroughly and recommended staff appointment. Many are familiar with the Gallup Plan of Massachusetts, which was promulgated for physicians from nonapproved schools. These physicians work under supervision for varying lengths of time depending upon demonstrated ability. This plan has functioned very well.

QUESTION.—*What are the recommendations of the Joint Commission on Accreditation of Hospitals regarding signatures and/or initials on a clinical chart? What about a rubber stamp? M.D., California.*

ANSWER.—First of all, initials are as valid as a full signature in court or any place, providing that the initials can be identified as belonging to the physician involved. The physician should be consistent and not sign his full name one time and initial the next time. Only use one or the other as your means of authenticating the clinical entries on a chart. Using a full signature many times can become an irritating chore. There is no reason why a legible first or last initial used consistently is not sufficient. If a physician wishes to use a rubber stamp the commission has no objection. The physician should place in the hands of the hospital administration a signed statement to the fact that he is the only person who will have possession of the stamp and is the only one who will use it. A rubber stamp is most commonly used by a pathologist or radiologist for signature purposes. The use of the rubber stamp for the physician by his office nurse or secretary is not condoned, and its promiscuous use could lead to trouble. A court would not accept a rubber stamp signature if it could be proved that it was used by other than the person whose name it bore.

QUESTION.—*Will a hospital be given demerits by the commission on the scoring report if it is found that nurses' aides or practical nurses are being used by a hospital as the "scrub" nurse or clean nurse? M.D., Pennsylvania.*

ANSWER.—The work of a "scrub" nurse or clean nurse is considered to be mostly mechanical, and it is not necessary to use a graduate nurse in this capacity. This was proved by the armed services during the last war; they trained corpsmen or technicians to do this work, and they did a wonderful job. With the shortage of graduate nurses still critical, hospitals can alleviate the situation by training ancillary personnel to do some of the mechanics of nursing like those duties performed in operating rooms and nurseries. Never forget, however, that such persons must always be supervised by a trained graduate nurse.

QUESTION.—*Some of our staff physicians want to interpret the electrocardiographic examinations performed on their own patients. What is the recommendation of the Joint Commission on Accreditation of Hospitals in this respect? Internist, Ohio.*

ANSWER.—The interpretation of an electrocardiographic examination is much like any other work performed in the hospital. It is a privilege that should be granted to a physician or physicians by the credentials committee of the medical staff, taking into account the applicant's training, qualifications, experience, and demonstrated ability. There is no doubt that the value of such a test diminishes considerably if it is "read" by unqualified personnel. The interpreter's signed report should be a part of the patient's chart and part of the record. It is the privilege of the physician on the case to express any opinion or comment on the electrocardiogram in the progress notes if he so desires.

QUESTION.—*Is a cancer registry necessary in order that our hospital be approved? We have been told it is a requirement.* *M.D., Indiana.*

ANSWER.—No. The commission does not require a cancer clinic or a cancer registry in a hospital that is seeking accreditation. A firm selling printed forms for use as cancer registers has been guilty of making a misstatement concerning this matter. The correct statement should have been, "Those hospitals having cancer clinics and desiring American College of Surgeons approval for same must have, among other requirements, a cancer registry." This is a requirement of the College of Surgeons in their special program and has no bearing on accreditation by the commission.

MEDICAL STAFF MEETINGS

The following information concerning medical staff meetings is reproduced from the August bulletin of the Joint Commission on Accreditation of Hospitals, 660 N. Rush St., Chicago; Kenneth B. Babcock, M.D., director.

Medical Staff Meetings Are Important!

From the start of the American College of Surgeons Hospital Standardization Program in 1920, the holding of regular medical staff meetings has been one of the standards on which approval of a hospital has been based. In accepting the Standards for Hospital Accreditation established by the College, the Joint Commission on Accreditation of Hospitals endorsed this principle as sound and essential for good patient care.

The sole purpose of hospital medical staff meetings is to improve the quality of patient care by means of a critical review and evaluation of the work of the professional staff. This analysis must be done by the medical staff which should meet at frequent and regular intervals to accomplish this purpose.

Recognizing that differences exist in hospitals because of size, location, and medical staff organization, hospitals have a choice of *one* of the three following methods of fulfilling the medical staff meeting requirement:

1. *Monthly Meetings of the Entire Active Medical Staff.*

This method is particularly suited in the hospital of less than seventy-five beds which is not departmentalized. It is also well suited in the hospital where the medical staff is small and is organized to function as a committee of the whole.

2. *Monthly Departmental Meetings and Quarterly Meetings of the Entire Active Staff.*

This method may be adopted when a hospital is well organized and departmentalized, and when it has been found to be more effective than Choice 1 for adequate and efficient review of the work of the staff. More frequent departmental meetings will depend upon the size of the hospital and the number of patients treated. Many hospitals have found it advisable to hold weekly departmental meetings.

3. *Monthly or More Frequent Review of the Clinical Work by the Medical Records and Tissue Committee* (or by an Audit Committee which combines the functions of these two committees), *Plus Monthly Meetings of the Executive Committee of the Medical Staff and Quarterly Meetings of the Entire Active Medical Staff.*

If conscientiously carried out, this method is very effective in evaluating the quality of patient care.

Experience has shown that one of these three patterns of medical staff meetings will fit any hospital seeking accreditation, whether it be small or large, rural or urban, affiliated with a medical school or not.

There has been some confusion and misunderstanding among the medical profession and hospitals concerning the following aspects of hospital medical staff meetings:

1. *Frequency and Regularity of Meetings.* The regular monthly meetings as described in Choices 1, 2, or 3 with not less than twelve in each calendar year, are necessary for adequate and effective evaluation of patient care. This means that such meetings should be held during the summer vacation months, for patients are treated in the hospital during these periods and their care should be evaluated.

2. *Multiplicity of Meetings.* Numerous complaints have been voiced by the medical profession concerning the hardship of forced attendance at medical staff meetings of several hospitals to which they have appointments. This occurs because many physicians accept an impracticable multiplicity of active staff memberships. There is a growing feeling among the practicing profession that a physician should limit his active staff appointments to no more than two hospitals in order that he may best serve his patients and conserve his time and energy. If additional hospital facilities are desired by the physician, he may accept an associate, consulting, or courtesy staff appointment. Administrations of hospitals should cooperate with the medical profession by making beds readily available to physicians with other than active staff appointments.

3. *Combined Hospital Medical Staff Meetings.* In certain areas where the medical staff of two or more hospitals are identical, there may be a desire to combine the monthly staff meetings of the several hospitals into one time-saving meeting. This is not acceptable, for it defeats the prime objective of a medical staff meeting, the evaluation of the care given patients in a particular hospital.

4. *Attendance at Meetings.* Adequate and effective participation in the evaluation of patient care requires regular, conscientious attendance at meetings of the active medical staff, departments or committees. It is expected that members of the active medical staffs shall attend at least seventy-five per cent of these official meetings, unless excused by the Executive Committee of the medical staff for such exceptional conditions as sickness, absence from the community or because of medical emergencies.

5. The Standard of the Commission on the attendance of staff meetings pertains to the active medical staff members. It is the decision of the local hospital staff whether the attendance of associate staff members is required.

6. Departmental meetings and clinicopathologic conferences are not required by the Commission, although highly desirable and recommended. These are requirements of the Council on Medical Education and Hospitals of the American Medical Association for training programs.

Remember, the requirement for medical staff meetings of the Commission are minimum for quality patient care. Many hospital staffs exceed these requirements and for this they should be commended.

MEDICINE AND THE LAW

The Judicial Council has authorized the publication of the following opinions. These opinions, and others approved by the Judicial Council, will be published in "Medicine and the Law." These opinions will eventually be compiled and published separately as annotations to the Principles of Medical Ethics.

Question: A member of the American Medical Association has asked: May I indicate the location of my office, the nature of my practice, my office hours, and the like by the use of a sign located in the lobby of the building in which my offices are located?

Opinion: Chapter I, section 4 of the Principles of Medical Ethics proscribes the solicitation of patients, directly or indirectly, and points out that the most worthy and effective advertising is the establishment of a well-merited reputation for professional ability and fidelity. It states that "disregard of local customs and offenses against recognized ideals are unethical." It is the opinion of the Judicial Council that local customs vary from community to community, and therefore it is the obligation of the component medical society to determine whether in a given locality the use of such a sign would be an affront to the ideals of the community and bring discredit to the profession. It is the further opinion of the Council that both the physician who contemplates the use of such advertising and his component society should fully observe the precept of Chapter III, section 1 of the Principles, "A physician is expected to uphold the dignity and honor of his profession."

Question: A member of the American Medical Association has asked: I rendered professional service to a colleague who has medical care insurance. That colleague has offered me the insurance benefit he received to reimburse me for my expenses. May I ethically accept this remuneration?

Opinion: Chapter IV, sections 1 and 2 of the Principles state that a physician should cheerfully and without recompense give his professional services to physicians or their dependents. These sections recognize, however, that such services may take the attending physician away from his accustomed field of practice and cause him pecuniary loss. They provide, therefore, that if the physician who received medical care is in easy financial circumstances he may offer compensation to the physician who attended him for traveling expenses, which compensation may include an amount to provide in part for loss of time away from accustomed practice. The Judicial Council in its report to the House of Delegates at its Los Angeles, 1951, session stated, "If a physician or his dependents have insurance providing for medical or surgical care, then, in the opinion of the Council, a physician who renders such service may accept the insurance benefits without violating the provisions of Chapter III [now Chapter IV], sections 1 and 2 of the Principles." The Council reaffirms its 1951 statement.

Question: A member of the American Medical Association has asked: May I ethically obligate myself to render professional medical service for a fee that will be contingent upon the success or failure of litigation in which my professional services will play a part?

Opinion: Chapter I, section 6 of the Principles of Medical Ethics provides that remuneration received for professional services rendered the patient should be in the form and amount specifically announced to the patient at the time the service is rendered, or in the form of a subsequent statement. It is the opinion of the Judicial Council that the contracting for, or acceptance of, a contingent fee by a doctor, which is based on the outcome of litigation, whether settled or adjudicated, is unethical. The Judicial Council would point out that the laborer is worthy of his hire and that the physician, having only his services to sell, has an obligation to place a fair value on those services. Ethically this value should be based upon the value of the service rendered by the physician to the patient and not upon the uncertain outcome of a contingency that does not in any way relate to the value of the service. Furthermore, the Council is of the opinion that the physician's obligation to uphold the dignity and honor of his profession precludes him from entering into an arrangement of this nature because, if a fee is contingent upon the successful outcome of a claim, there is the ever-present danger that the physician may become less of a healer and more of an advocate—a situation that does not uphold the dignity of the profession of medicine.

PUBLIC RELATIONS

Public Attitudes About Physicians and Medical Care

Although random shots in the dark sometimes hit the mark, a clearly illuminated objective is a lot easier to hit. This is particularly true in public relations activities. If you know where to aim, you will come a lot closer to the bull's-eye and use less ammunition to do it. In order to spotlight more vividly the areas requiring concentrated public relations action, the Los Angeles County Medical Association has completed a public opinion survey in which the attitudes of the public and opinion leaders about doctors and medical care are assessed.

The study, involving a scientifically drawn sample of 360 people, elicited information in three areas: (1) humanitarianism of doctors, (2) doctors' fees, and (3) surgeons' fees versus hospital charges. A great deal of specific information in regard to public understanding of physicians and their work, attitudes about health insurance, and areas of public dissatisfaction was accumulated. One of the most encouraging things about the survey was that people do not take as dim a view of doctors as the doctors themselves sometimes think. In their ratings for humanitarianism physicians fared well with the public. More than 85% of those interviewd had positive attitudes about physicians in this respect as compared with less than 5% who had negative attitudes.

(According to survey experts, a finding of less than 10% is considered insignificant.) Over 80% of those interviewed, for example, felt physicians in general have a kindly, sympathetic interest in those who are ill or injured.

How do people feel about doctors as community leaders? Between 40% and 50% expressed the belief that doctors in general take about their share or more than their share of responsibility in community activities. Here a significant contrast in feeling was shown between members of the general public and opinion leaders. While less than 8% of the public said doctors shouldered less than their share of community responsibility, 40% of the opinion leaders said doctors did not do their share. Because dissatisfaction about long waits in doctors' offices is often cited as a leading factor creating poor public relations, the study probed opinions on this subject. The public reported that doctors keep people waiting an average of 5 out of 10 times, but, amazingly enough, over 80% felt this was reasonable. An average of 22 minutes was considered a "reasonable" wait to see the doctor.

Three important points were brought out in the study. First, the majority of those surveyed said they think the medical profession is doing a good job in informing the public about new methods, treatments, and medicines. Second, over one-third of the respondents expressed a desire to discuss fees in advance of treatment. Third, an overwhelming majority (70%) expressed a desire for itemized medical bills. Yet the picture painted by those surveyed was not all quite so rosy. Glaring misconceptions about certain aspects of medical practice were revealed along with some definitely unfavorable attitudes about the practice of medicine. These are the trouble spots upon which Los Angeles physicians will concentrate their public relations efforts.

Although the study showed that over 60% of the people think doctors' fees are reasonable, there are many areas of dissatisfaction in regard to costs. Many said that medical costs have risen in greater proportion than other costs, revealing fairly widespread ignorance of the facts. Another significant finding was that about 22% of the general public and 48% of the opinion leaders said they knew of individuals requiring medical treatment who were not receiving it because doctors' fees alone are too high. The effect of hearsay and rumor on public opinion was clearly shown in the answers to questions about physicians' fees. Between 88% and 89% said that the last time they went to a doctor his fee was reasonable. Yet, when the same group was asked whether doctors' fees in general were reasonable, only 60% said yes. Hospital fees, in comparison, were listed as unreasonable by almost 48% of the general public and by 35% of the opinion leaders. How do people compare surgeons' fees and hospital fees? About 40% of the general public and 31% of the opinion leaders said surgeons' fees were greater than hospital fees. A slightly larger percentage of the general public (43%) and the same percentage of opinion leaders felt hospital charges were greater.

A definite lack of information was revealed by the fact that between 55% and 60% of the public could not correctly define "D.O." and "D.C." More serious misconceptions were uncovered by the finding that one-third of the general public believed that doctors get a rebate or kickback from druggists on prescriptions. In addition, about 26% of the general public and 15% of the opinion leaders said there was a lot of unnecessary surgery performed by doctors in the Los Angeles area. About 26% of the public and 49% of the leaders felt there was a little unnecessary surgery performed. One encouraging finding was that 86% of the general public and 92% of the opinion leaders had heard of the Los Angeles County Medical Association and the American Medical Association and about 70% of both groups had heard of the California Medical Association.

Public Relations Problem into Purposeful Project

Back in 1951 physicians in Phoenix, Ariz., became disturbed about the inadequate facilities for caring for patients in local rest homes. Members of the Maricopa County Medical Society, deciding to do something about the situation, launched a study of every rest home in the county, and, on the basis of additional information provided by other states and counties, compiled a set of standards for nursing and boarding homes. Enlisting the cooperation of the city fire department and sanitary officials, physicians conducted a campaign to eliminate fire hazards and to make sure food preparation and sanitary facilities in these homes met the standards.

Home operators in general were cooperative and attempted to make improvements. A 30-day period elapsed after preliminary checks had been made and home operators had been notified of the changes necessary to meet the society's standards. At the end of this period the medical society in a lengthy report protested vigorously to city officials about the deficiencies still existing in some homes. As a result, city, county, and state health departments have assumed responsibility for licensing and enforcing code standards. Out of the four-year campaign sparked and brought to a happy conclusion by Phoenix physicians has come an even more lasting achievement—a new county rest home is being erected on the grounds of the present county hospital.

PRoblem Corner

At the conclusion of his residency a young doctor moved to another state and secured a license to practice medicine. He immediately found himself faced with a problem. The local Lions Club in the little town in which he was setting up practice wanted to help him get started. Its members offered to print and circulate announcement cards to townspeople. The young doctor was uncertain whether such an action was ethical, and there was no other doctor practicing in the town to provide him with an answer. Fortunately, he checked with the county medical society and learned that such practices are generally based upon local custom and in his particular area the procedure would have been frowned upon by other physicians.

Some public relations problems are intraprofessional rather than external in nature. Hasty or ill-advised actions by physicians that incur the disapproval of other doctors in the area by flouting local custom create just such intraprofessional public relations problems. The best advice in such cases is this: when in doubt, check with your local society.

MEDICAL NEWS

CALIFORNIA

Students Pledge Financial Aid.—According to Dr. Ewing L. Turner, president of the Los Angeles County Medical Association, the pledging by medical students of $264,000 toward construction of the new Southern California Medical Center "has no parallel in the history of medical education." The sum was promised by 270 students of the University of Southern California School of Medicine, Los Angeles, who pledged to pay their money within three years after entering practice. Of the freshman and junior classes, 100% pledged. Only 3 of the 270 students in the school did not sign pledge cards, and 2 of these indicated they would do so when they actually entered practice. The average pledge was $1,000.

More Rabies in Animals.—According to a statement by Dr. Malcolm H. Merrill, state director of public health, "The state is now facing the largest and the most geographically extensive reservoir of animal rabies infection that it has experienced in many years, with rabies endemic in 22 counties." A statewide tally of 165 confirmed cases of animal rabies to July 20 disclosed that the city and county of Los Angeles accounted for nearly half of all rabies reported in California. There were 43 diagnosed cases of animal rabies in the city of Los Angeles between Jan. 1 and July 20—more cases than in any similar period since 1948. All rabies cases in Los Angeles were found among dogs; elsewhere in the state, 83 cases were confirmed among other animals, including cows, skunks, foxes, bobcats, and a goat. A statewide meeting on the problem was held recently in Berkeley.

Course in Aviation Medicine.—The University of California Extension will offer a course in aviation medicine Oct. 26-28, 9-12 a. m. and 1-5 p. m., in the Religious Conference Building, 900 Hilgard Ave., Los Angeles. The course, which is open to graduates of approved medical schools, is designed for the doctor who examines the student and private pilot as well as for the doctor who is a flight surgeon. Speakers at a dinner meeting on Wednesday will be Dr. Stafford L. Warren, Los Angeles, and Col. Richard L. Bohannon, M. C., U. S. A. F. In addition to lectures on aviation toxicology, psychology, and otolaryngology, the course will include a field trip to Lockheed Aircraft Corporation, Burbank. Dr. Bruce V. Leamer, Los Angeles, is chairman of the course. The fee of $50 will include one dinner meeting. Applications should be addressed to Dr. Thomas H. Sternberg, Assistant Dean for Postgraduate Medical Education, Medical Extension, University of California, Los Angeles 24.

CONNECTICUT

Hartford Medical Society Fall Lectures.—The first lecture in the Hartford Medical Society fall series, "Metabolic Considerations in Mental Disorders," was delivered on Oct. 3 by Dr. Mark D. Altschule, Waverley, Mass. Lectures for 1955, to be delivered at the Hunt Memorial, 38 Prospect St., Hartford, 8:30 p. m., include:

Oct. 17, Evaluation of Therapy in Disease, Stewart Wolf, Oklahoma City.

Nov. 7, Immunohematology in Clinical Practice, William Dameshek, Boston.

Nov. 21, Diagnosis and Treatment of Tumors of the Soft Somatic Tissues, George T. Pack, New York.

Dec. 5, Poliomyelitis—1955, Louis Weinstein, Boston.

All physicians are invited to attend.

Arthritis Study Unit.—The purposes of the Arthritis Study Unit of Yale University School of Medicine, which is made up of faculty members, are to stimulate teaching and research in arthritis and to hold conferences at which scientific papers are presented. The unit announces the following lectures, 3:30-4:30 p. m., in the Fitkin Amphitheatre, Yale-New Haven Medical Center:

Oct. 20, Significant Clinical Remissions in Rheumatoid Arthritis Resulting from Hypersensitivity Produced by Gold Salt Therapy, Theodore B. Bayles, Boston.

Nov. 17, Distinction Between Rheumatoid Arthritis and Systemic Lupus Erythematosus, Charles Ragan, New York.

Dec. 15, Globulin Factors in the Sensitized Sheep Cell Agglutination Reaction, Morris Ziff, New York.

DELAWARE

State Medical Meeting in Wilmington.—The Medical Society of Delaware will hold its annual meeting at the Delaware Academy of Medicine in Wilmington Oct. 17-18. After welcoming remarks by Dr. Norman L. Cutler, Wilmington, president, New Castle County Medical Society, and Dr. Victor D. Washburn, Wilmington, president, Delaware Academy of Medicine, the presidential address will be delivered by Dr. Lewis B. Flinn, Wilmington, who will serve as moderator for a panel discussion, "Vitamins and Other Nutrition Factors in Clinical Practice," at 9 p. m. Monday; a panel discussion, "Current Concepts of Virus Disease in the Delaware Area," at 10:45 a. m. Tuesday; and a panel discussion at 3:40 p. m. on the management of vascular disease. Out-of-state speakers include: Drs. Robert S. Goodhart, New York; Winslow T. Tompkins, Robert G. Ravdin, Robert Kaye, Joseph Stokes Jr., Werner Henle, John P. Hubbard, Samuel B. Hadden, Charles P. Bailey, and Harry F. Zinsser, Philadelphia; Dorothy M. Horstmann, New Haven, Conn.; and Henry T. Bahnson, Baltimore. A reception, 6:45 p. m. Tuesday, will precede the annual banquet, at which an address will be delivered by Dr. Edward L. Bortz, Philadelphia, Past-President of the American Medical Association, who will have as his subject "Significant Trends in Medical Education." The woman's auxiliary will meet simultaneously at the DuPont Country Club.

GEORGIA

Dr. Pund on Lecture Tour.—Dr. Edgar R. Pund, president of the Medical College of Georgia, Augusta, has been appointed consultant to the surgeon general for a 30 day inspection and lecture tour of medical facilities of the U. S. Army in the Far East. Dr. Pund left Washington, D. C., Sept. 30, and at Camp Zama, near Tokyo, he held a conference with the chiefs of staff. He will lecture at the 406th Medical General Laboratory, 121st Evacuation Hospital, National Institute for Prevention of Infectious Diseases, Seoul National University Medical School, National Chemical Laboratories, 38th Parallel Medical Society, Hiroshima Medical School, Kyoto University Medical School, Tokyo University School of Medicine, and the Japanese-American Society of Pathologists.

ILLINOIS

Annual General Practitioners Meeting.—The eighth annual scientific assembly of the Illinois Academy of General Practice will be held Oct. 25-27 at the Illinois State Armory, Springfield, under the presidency of Dr. Dewey M. Roberts, Alton. Tuesday's program at the Hotel Leland will conclude at 7:15 p. m. with the delegates' dinner. At 11 a. m. Wednesday, during the scientific assembly at the armory, Dr. Charles O. McCormick Sr., Indianapolis, will serve as moderator for a round-table on prolonged labor, which will have as participants Drs. John F. Spahr Jr. and Charles O. McCormick Jr., Indianapolis, and Dr. Robert M. Myers, Kansas City, Mo. On Wednesday and Thursday at 12:15 p. m. there will be a round-table luncheon at the Hotel Leland, with Dr. Dewey M. Roberts, president, and Dr. George S. Schwerin, Chicago, president-elect, as moderators. A clinicopathological conference, 3:45 p. m. Wednesday, will have as participants Dr. William H. Requarth, Decatur, and Dr. Harold M. Feinberg, Chicago, with Dr. Coye C. Mason, Chicago, as

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

moderator. At the banquet Dr. John R. Fowler, Barre, Mass., president, American Academy of General Practice, will discuss "The Good Physician." A panel discussion on the drug treatment of hypertension, 3:15 p. m. Thursday, will have as moderator Dr. Michael Serio, Chicago, and will include presentation of "Clinical Pharmacology of the Newer Hypotensive Drugs" by Dr. Charles W. Crumpton, Madison; "Drugs of Choice in the Treatment of Hypertension Associated with Heart Disease and Impaired Renal Function" by Dr. Alfred D. Dennison Jr., Indianapolis; and "The Drug Treatment of Primary Essential Hypertension" by Dr. James H. Currens, Boston. Presentations by out-of-state speakers include:

A Manikin Demonstration Lecture Covering the Common Obstetrical Maneuvers and the Use of Forceps, John F. Spahr Jr., Indianapolis.
A Study of the Infertile Couple, Charles O. McCormick Jr., Indianapolis.
Office Gynecologic Problems, Robert M. Myers, Kansas City, Mo.
Management of Threatened and Habitual Abortion, Robert B. Greenblatt, Augusta, Ga.
Using the Laboratory in Liver Diseases, William A. Sodeman, Columbia, Mo.
The Diarrheal Syndrome, Jerome Weiss, New York.
Diagnostic Problems in Gouty Rheumatoid Arthritis, Robert L. McClendon, Louisville, Ky.
The Arthritis Problem and the General Practitioner, Kenneth D. Bryson, Cleveland.
Arthritis Problems Discussed, Robert L. McClendon, Louisville, Ky., and Kenneth D. Bryson, Cleveland.

Chicago

University News.—The University of Illinois College of Medicine has announced the promotion of Dr. Harold Shellow from assistant professor of dermatology to associate professor.

Lecture on Noise.—The Chicago Society of Industrial Medicine and Surgery and the Casualty Adjusters Association of Chicago will hold a joint meeting at the Bismarck Hotel Oct. 19, 7:30 p. m. "The Wisconsin Story of the Industrial Noise Problem" will be presented by Dr. Meyer S. Fox of Marquette University School of Medicine, Milwaukee.

Medical History Meeting.—The Society of Medical History of Chicago will hold an open meeting Oct. 19, 8 p. m., at the Institute of Medicine (fourth floor, 86 E. Randolph St.). The program includes:

Nikolai Ivanovich Pirgov—Anatomist, Surgeon, Educator, George Halperin.
The Migration of Diseases, Dieter Koch-Weser.
John Keats, a Medical Truant, Miss Esther Vincent.

All are welcome.

Gynecologic Society Meeting.—The regular meeting of the Chicago Gynecological Society will be held at the Knickerbocker Hotel Oct. 21, 8 p. m. The sixth annual Joseph L. Baer Lecture, "The Management of Cervical Carcinoma," will be delivered by Dr. Joe V. Meigs, clinical professor of gynecology, Harvard Medical School, Boston. The clinical meeting will be held at Passavant Memorial Hospital, 303 E. Superior St., 9 a. m., on the same day.

INDIANA

State Medical Meeting.—The Indiana State Medical Association will hold its 106th annual convention at the French Lick Springs Hotel, French Lick, Oct. 16-19. Dr. Walter L. Portteus, Franklin, will deliver the presidential address Tuesday at 7 p. m. Tuesday round-table discussions, 10:30-12 noon, will be presented on (1) Obstetrics and Gynecology (Dr. Sprague H. Gardiner, Indianapolis, moderator); (2) Daily Dermatological Dilemmas (Dr. Lawrence G. Beinhauer, Pittsburgh, moderator); (3) Fluid and Electrolyte Balance (Dr. William D. Snively Jr., Evansville, moderator); and (4) Management of Hypertension (film from Wyeth Laboratories, Philadelphia). Wednesday round-table discussions, 10:30-12 noon, include (1) Modern Day Burns—Their Treatment (Dr. Harold M. Trusler, Indianapolis, moderator); (2) Medical Treatment—Industrial Cases (Dr. Eli S. Jones, Hammond, moderator); (3) Collagen Diseases (Dr. John G. Rukavina, Ann Arbor, Mich., moderator); and (4) Radioisotopes (Dr. John A. Campbell, Indianapolis, moderator). At the general meeting Tuesday, 2 p. m., traffic accidents will be discussed. Sgt. Elmer Paul, Indiana State Police, Indianapolis, and John O. Moore, director, Indiana-Cornell Automotive Crash Injury Research, Cornell University Medical College, New York, will discuss "How They Are Killed and Injured." "Traffic Accidents—Their Treatment" will be considered at 3:30 p. m. by Dr. Robert E. Slemmer, Cincinnati (Neurological Aspects); Dr. Claire L. Straith, Detroit (Maxillofacial Injuries); Dr. Richard W. Zollinger, Columbus, Ohio (General Surgery); and Dr. George J. Garceau, Indianapolis (Orthopedic Injuries). The meeting of the section on medicine Wednesday, 2 p. m., will include presentation of "Familial Primary Systemic Amyloidosis: A Clinical, Genetic, and Biochemical Study" by Dr. Rukavina. Dr. Brant B. Sankey, Cleveland, Ohio, will speak before the section on anesthesiology, which meets simultaneously. Dr. C. Paul Hodgkinson, Detroit, will serve as moderator for the round-table discussions, 1:30 p. m. Wednesday, during the meeting of the section on obstetrics and gynecology. The section on public health and preventive medicine will hold a round-table in conjunction with the sections on medicine and general practice in the Main Convention Hall, 3:30-5 p. m. Wednesday. The sections on ophthalmology and otolaryngology, general practice, and surgery will also meet at 2 p. m. Wednesday. Dr. Dwight H. Murray, Napa, Calif., President-Elect, American Medical Association, will speak at the annual dinner Wednesday, 7 p. m. The program includes instructional courses from 2 to 4 p. m. Monday and from 8:30-10:30 a. m. Tuesday and Wednesday. The annual golf tournament will be held at 8 a. m. Monday at the French Lick Hill course and the annual trap and skeet shoot, 9 a. m. at the French Lick Springs Trap and Skeet Club. The woman's auxiliary will meet Oct. 17-19.

KANSAS

Dr. Dock to Give Porter Lectures.—The University of Kansas School of Medicine, Kansas City, announces the 1955 course of Porter Lectures to be given by Dr. William Dock, professor of medicine, State University of New York College of Medicine at New York City, Brooklyn. On Oct. 18 at 4 p. m. in the J. R. Battenfeld Jr. Memorial Auditorium, Kansas City, Dr. Dock will present "Clinical Significance of Pulsations Evoked by the Heart Beat." He will discuss "Coronary Disease—The Professor's Friend" in Strong Hall, Lawrence campus, Oct. 19, 11 a. m., and at 4 p. m. the same day he will present "The Production of Sounds by Normal and Diseased Hearts" at the Battenfeld auditorium. Physicians and students are invited.

MASSACHUSETTS

Society of Examining Physicians.—The fall supper meeting of the Massachusetts Society of Examining Physicians will be held at the Harvard Club in Boston, 6 p. m. Oct. 19. A symposium on "The Painful Neck Syndrome" will be presented by Drs. Richard M. Kilfoyle, Boston, orthopedic surgeon; Walter R. Wegner, Boston, neurosurgeon; Albert M. Moloney, Boston, roentgenologist; and Arthur L. Watkins, Boston, consultant in physical medicine. All physicians are cordially invited.

MINNESOTA

Dr. Aldrich Returns to Chicago.—Dr. C. Knight Aldrich, associate professor of psychiatry, University of Minnesota Medical School, Minneapolis, has been appointed chairman, department of psychiatry, University of Chicago School of Medicine. A native of Chicago, Dr. Aldrich served his internship at Cook County Hospital. For five years he was a psychiatrist with the U. S. Public Health Service. He joined the faculty of the University of Minnesota Medical School in 1947. He also has served as a consultant to the Veteran's Administration Hospital, Minneapolis, and to the Family and Children's Service of Minneapolis. He is the author of "Psychiatry for the Family Doctor," the Medical Book Guild's August selection.

MISSISSIPPI

Two Professors Appointed.—The University of Mississippi School of Medicine in Jackson announces the appointment of Dr. Robert D. Sloan, who has been on the staff at Johns Hopkins University School of Medicine, Baltimore, as professor of

MEDICAL NEWS

CALIFORNIA

Students Pledge Financial Aid.—According to Dr. Ewing L. Turner, president of the Los Angeles County Medical Association, the pledging by medical students of $264,000 toward construction of the new Southern California Medical Center "has no parallel in the history of medical education." The sum was promised by 270 students of the University of Southern California School of Medicine, Los Angeles, who pledged to pay their money within three years after entering practice. Of the freshman and junior classes, 100% pledged. Only 3 of the 270 students in the school did not sign pledge cards, and 2 of these indicated they would do so when they actually entered practice. The average pledge was $1,000.

More Rabies in Animals.—According to a statement by Dr. Malcolm H. Merrill, state director of public health, "The state is now facing the largest and the most geographically extensive reservoir of animal rabies infection that it has experienced in many years, with rabies endemic in 22 counties." A statewide tally of 165 confirmed cases of animal rabies to July 20 disclosed that the city and county of Los Angeles accounted for nearly half of all rabies reported in California. There were 43 diagnosed cases of animal rabies in the city of Los Angeles between Jan. 1 and July 20—more cases than in any similar period since 1948. All rabies cases in Los Angeles were found among dogs; elsewhere in the state, 83 cases were confirmed among other animals, including cows, skunks, foxes, bobcats, and a goat. A statewide meeting on the problem was held recently in Berkeley.

Course in Aviation Medicine.—The University of California Extension will offer a course in aviation medicine Oct. 26-28, 9-12 a. m. and 1-5 p. m., in the Religious Conference Building, 900 Hilgard Ave., Los Angeles. The course, which is open to graduates of approved medical schools, is designed for the doctor who examines the student and private pilot as well as for the doctor who is a flight surgeon. Speakers at a dinner meeting on Wednesday will be Dr. Stafford L. Warren, Los Angeles, and Col. Richard L. Bohannon, M. C., U. S. A. F. In addition to lectures on aviation toxicology, psychology, and otolaryngology, the course will include a field trip to Lockheed Aircraft Corporation, Burbank. Dr. Bruce V. Leamer, Los Angeles, is chairman of the course. The fee of $50 will include one dinner meeting. Applications should be addressed to Dr. Thomas H. Sternberg, Assistant Dean for Postgraduate Medical Education, Medical Extension, University of California, Los Angeles 24.

CONNECTICUT

Hartford Medical Society Fall Lectures.—The first lecture in the Hartford Medical Society fall series, "Metabolic Considerations in Mental Disorders," was delivered on Oct. 3 by Dr. Mark D. Altschule, Waverley, Mass. Lectures for 1955, to be delivered at the Hunt Memorial, 38 Prospect St., Hartford, 8:30 p. m., include:

Oct. 17, Evaluation of Therapy in Disease, Stewart Wolf, Oklahoma City.

Nov. 7, Immunohematology in Clinical Practice, William Dameshek, Boston.

Nov. 21, Diagnosis and Treatment of Tumors of the Soft Somatic Tissues, George T. Pack, New York.

Dec. 5, Poliomyelitis—1955, Louis Weinstein, Boston.

All physicians are invited to attend.

Arthritis Study Unit.—The purposes of the Arthritis Study Unit of Yale University School of Medicine, which is made up of faculty members, are to stimulate teaching and research in arthritis and to hold conferences at which scientific papers are presented. The unit announces the following lectures, 3:30-4:30 p. m., in the Fitkin Amphitheatre, Yale-New Haven Medical Center:

Oct. 20, Significant Clinical Remissions in Rheumatoid Arthritis Resulting from Hypersensitivity Produced by Gold Salt Therapy, Theodore B. Bayles, Boston.

Nov. 17, Distinction Between Rheumatoid Arthritis and Systemic Lupus Erythematosus, Charles Ragan, New York.

Dec. 15, Globulin Factors in the Sensitized Sheep Cell Agglutination Reaction, Morris Ziff, New York.

DELAWARE

State Medical Meeting in Wilmington.—The Medical Society of Delaware will hold its annual meeting at the Delaware Academy of Medicine in Wilmington Oct. 17-18. After welcoming remarks by Dr. Norman L. Cutler, Wilmington, president, New Castle County Medical Society, and Dr. Victor D. Washburn, Wilmington, president, Delaware Academy of Medicine, the presidential address will be delivered by Dr. Lewis B. Flinn, Wilmington, who will serve as moderator for a panel discussion, "Vitamins and Other Nutrition Factors in Clinical Practice," at 9 p. m. Monday; a panel discussion, "Current Concepts of Virus Disease in the Delaware Area," at 10:45 a. m. Tuesday; and a panel discussion at 3:40 p. m. on the management of vascular disease. Out-of-state speakers include: Drs. Robert S. Goodhart, New York; Winslow T. Tompkins, Robert G. Ravdin, Robert Kaye, Joseph Stokes Jr., Werner Henle, John P. Hubbard, Samuel B. Hadden, Charles P. Bailey, and Harry F. Zinsser, Philadelphia; Dorothy M. Horstmann, New Haven, Conn.; and Henry T. Bahnson, Baltimore. A reception, 6:45 p. m. Tuesday, will precede the annual banquet, at which an address will be delivered by Dr. Edward L. Bortz, Philadelphia, Past-President of the American Medical Association, who will have as his subject "Significant Trends in Medical Education." The woman's auxiliary will meet simultaneously at the DuPont Country Club.

GEORGIA

Dr. Pund on Lecture Tour.—Dr. Edgar R. Pund, president of the Medical College of Georgia, Augusta, has been appointed consultant to the surgeon general for a 30 day inspection and lecture tour of medical facilities of the U. S. Army in the Far East. Dr. Pund left Washington, D. C., Sept. 30, and at Camp Zama, near Tokyo, he held a conference with the chiefs of staff. He will lecture at the 406th Medical General Laboratory, 121st Evacuation Hospital, National Institute for Prevention of Infectious Diseases, Seoul National University Medical School, National Chemical Laboratories, 38th Parallel Medical Society, Hiroshima Medical School, Kyoto University Medical School, Tokyo University School of Medicine, and the Japanese-American Society of Pathologists.

ILLINOIS

Annual General Practitioners Meeting.—The eighth annual scientific assembly of the Illinois Academy of General Practice will be held Oct. 25-27 at the Illinois State Armory, Springfield, under the presidency of Dr. Dewey M. Roberts, Alton. Tuesday's program at the Hotel Leland will conclude at 7:15 p. m. with the delegates' dinner. At 11 a. m. Wednesday, during the scientific assembly at the armory, Dr. Charles O. McCormick Sr., Indianapolis, will serve as moderator for a round-table on prolonged labor, which will have as participants Drs. John F. Spahr Jr. and Charles O. McCormick Jr., Indianapolis, and Dr. Robert M. Myers, Kansas City, Mo. On Wednesday and Thursday at 12:15 p. m. there will be a round-table luncheon at the Hotel Leland, with Dr. Dewey M. Roberts, president, and Dr. George S. Schwerin, Chicago, president-elect, as moderators. A clinicopathological conference, 3:45 p. m. Wednesday, will have as participants Dr. William H. Requarth, Decatur, and Dr. Harold M. Feinberg, Chicago, with Dr. Coye C. Mason, Chicago, as

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

moderator. At the banquet Dr. John R. Fowler, Barre, Mass., president, American Academy of General Practice, will discuss "The Good Physician." A panel discussion on the drug treatment of hypertension, 3:15 p. m. Thursday, will have as moderator Dr. Michael Serio, Chicago, and will include presentation of "Clinical Pharmacology of the Newer Hypotensive Drugs" by Dr. Charles W. Crumpton, Madison; "Drugs of Choice in the Treatment of Hypertension Associated with Heart Disease and Impaired Renal Function" by Dr. Alfred D. Dennison Jr., Indianapolis; and "The Drug Treatment of Primary Essential Hypertension" by Dr. James H. Currens, Boston. Presentations by out-of-state speakers include:

A Manikin Demonstration Lecture Covering the Common Obstetrical Maneuvers and the Use of Forceps, John F. Spahr Jr., Indianapolis.
A Study of the Infertile Couple, Charles O. McCormick Jr., Indianapolis.
Office Gynecologic Problems, Robert M. Myers, Kansas City, Mo.
Management of Threatened and Habitual Abortion, Robert B. Greenblatt, Augusta, Ga.
Using the Laboratory in Liver Diseases, William A. Sodeman, Columbia, Mo.
The Diarrheal Syndrome, Jerome Weiss, New York.
Diagnostic Problems in Gouty Rheumatoid Arthritis, Robert L. McClendon, Louisville, Ky.
The Arthritis Problem and the General Practitioner, Kenneth D. Bryson, Cleveland.
Arthritis Problems Discussed, Robert L. McClendon, Louisville, Ky., and Kenneth D. Bryson, Cleveland.

Chicago

University News.—The University of Illinois College of Medicine has announced the promotion of Dr. Harold Shellow from assistant professor of dermatology to associate professor.

Lecture on Noise.—The Chicago Society of Industrial Medicine and Surgery and the Casualty Adjusters Association of Chicago will hold a joint meeting at the Bismarck Hotel Oct. 19, 7:30 p. m. "The Wisconsin Story of the Industrial Noise Problem" will be presented by Dr. Meyer S. Fox of Marquette University School of Medicine, Milwaukee.

Medical History Meeting.—The Society of Medical History of Chicago will hold an open meeting Oct. 19, 8 p. m., at the Institute of Medicine (fourth floor, 86 E. Randolph St.). The program includes:

Nikolai Ivanovich Pirgov—Anatomist, Surgeon, Educator, George Halperin.
The Migration of Diseases, Dieter Koch-Weser.
John Keats, a Medical Truant, Miss Esther Vincent.

All are welcome.

Gynecologic Society Meeting.—The regular meeting of the Chicago Gynecological Society will be held at the Knickerbocker Hotel Oct. 21, 8 p. m. The sixth annual Joseph L. Baer Lecture, "The Management of Cervical Carcinoma," will be delivered by Dr. Joe V. Meigs, clinical professor of gynecology, Harvard Medical School, Boston. The clinical meeting will be held at Passavant Memorial Hospital, 303 E. Superior St., 9 a. m., on the same day.

INDIANA

State Medical Meeting.—The Indiana State Medical Association will hold its 106th annual convention at the French Lick Springs Hotel, French Lick, Oct. 16-19. Dr. Walter L. Portteus, Franklin, will deliver the presidential address Tuesday at 7 p. m. Tuesday round-table discussions, 10:30-12 noon, will be presented on (1) Obstetrics and Gynecology (Dr. Sprague H. Gardiner, Indianapolis, moderator); (2) Daily Dermatological Dilemmas (Dr. Lawrence G. Beinhauer, Pittsburgh, moderator); (3) Fluid and Electrolyte Balance (Dr. William D. Snively Jr., Evansville, moderator); and (4) Management of Hypertension (film from Wyeth Laboratories, Philadelphia). Wednesday round-table discussions, 10:30-12 noon, include (1) Modern Day Burns—Their Treatment (Dr. Harold M. Trusler, Indianapolis, moderator); (2) Medical Treatment—Industrial Cases (Dr. Eli S. Jones, Hammond, moderator); (3) Collagen Diseases (Dr. John G. Rukavina, Ann Arbor, Mich., moderator); and (4) Radioisotopes (Dr. John A. Campbell, Indianapolis, moderator). At the general meeting Tuesday, 2 p. m., traffic accidents will be discussed. Sgt. Elmer Paul, Indiana State Police, Indianapolis, and John O. Moore, director, Indiana-Cornell Automotive Crash Injury Research, Cornell University Medical College, New York, will discuss "How They Are Killed and Injured." "Traffic Accidents—Their Treatment" will be considered at 3:30 p. m. by Dr. Robert E. Slemmer, Cincinnati (Neurological Aspects); Dr. Claire L. Straith, Detroit (Maxillofacial Injuries); Dr. Richard W. Zollinger, Columbus, Ohio (General Surgery); and Dr. George J. Garceau, Indianapolis (Orthopedic Injuries). The meeting of the section on medicine Wednesday, 2 p. m., will include presentation of "Familial Primary Systemic Amyloidosis: A Clinical, Genetic, and Biochemical Study" by Dr. Rukavina. Dr. Brant B. Sankey, Cleveland, Ohio, will speak before the section on anesthesiology, which meets simultaneously. Dr. C. Paul Hodgkinson, Detroit, will serve as moderator for the round-table discussions, 1:30 p. m. Wednesday, during the meeting of the section on obstetrics and gynecology. The section on public health and preventive medicine will hold a round-table in conjunction with the sections on medicine and general practice in the Main Convention Hall, 3:30-5 p. m. Wednesday. The sections on ophthalmology and otolaryngology, general practice, and surgery will also meet at 2 p. m. Wednesday. Dr. Dwight H. Murray, Napa, Calif., President-Elect, American Medical Association, will speak at the annual dinner Wednesday, 7 p. m. The program includes instructional courses from 2 to 4 p. m. Monday and from 8:30-10:30 a. m. Tuesday and Wednesday. The annual golf tournament will be held at 8 a. m. Monday at the French Lick Hill course and the annual trap and skeet shoot, 9 a. m. at the French Lick Springs Trap and Skeet Club. The woman's auxiliary will meet Oct. 17-19.

KANSAS

Dr. Dock to Give Porter Lectures.—The University of Kansas School of Medicine, Kansas City, announces the 1955 course of Porter Lectures to be given by Dr. William Dock, professor of medicine, State University of New York College of Medicine at New York City, Brooklyn. On Oct. 18 at 4 p. m. in the J. R. Battenfeld Jr. Memorial Auditorium, Kansas City, Dr. Dock will present "Clinical Significance of Pulsations Evoked by the Heart Beat." He will discuss "Coronary Disease—The Professor's Friend" in Strong Hall, Lawrence campus, Oct. 19, 11 a. m., and at 4 p. m. the same day he will present "The Production of Sounds by Normal and Diseased Hearts" at the Battenfeld auditorium. Physicians and students are invited.

MASSACHUSETTS

Society of Examining Physicians.—The fall supper meeting of the Massachusetts Society of Examining Physicians will be held at the Harvard Club in Boston, 6 p. m. Oct. 19. A symposium on "The Painful Neck Syndrome" will be presented by Drs. Richard M. Kilfoyle, Boston, orthopedic surgeon; Walter R. Wegner, Boston, neurosurgeon; Albert M. Moloney, Boston, roentgenologist; and Arthur L. Watkins, Boston, consultant in physical medicine. All physicians are cordially invited.

MINNESOTA

Dr. Aldrich Returns to Chicago.—Dr. C. Knight Aldrich, associate professor of psychiatry, University of Minnesota Medical School, Minneapolis, has been appointed chairman, department of psychiatry, University of Chicago School of Medicine. A native of Chicago, Dr. Aldrich served his internship at Cook County Hospital. For five years he was a psychiatrist with the U. S. Public Health Service. He joined the faculty of the University of Minnesota Medical School in 1947. He also has served as a consultant to the Veteran's Administration Hospital, Minneapolis, and to the Family and Children's Service of Minneapolis. He is the author of "Psychiatry for the Family Doctor," the Medical Book Guild's August selection.

MISSISSIPPI

Two Professors Appointed.—The University of Mississippi School of Medicine in Jackson announces the appointment of Dr. Robert D. Sloan, who has been on the staff at Johns Hopkins University School of Medicine, Baltimore, as professor of radiology and chairman of the department. Another Johns Hopkins staff member, Dr. Blair E. Batson, will become professor of pediatrics and chairman of that department in Mississippi's four-year school of medicine in the newly built University Medical Center.

NEW YORK

Academy of Medicine Meeting.—The monthly meeting of the Binghamton Academy of Medicine will be held Oct. 18, 8:45 p. m., at Binghamton City Hospital, Binghamton. Dr. G. W. H. Schepers, Saranac Lake, will speak on pneumonoconiosis.

Annual Meeting of Practitioners.—The seventh annual scientific assembly of the New York State Academy of General Practice will convene at the Hotel Statler, New York City, Oct. 17-20. The sessions will open with a welcoming address by Dr. Garra L. Lester, Chautauqua, president of the academy, and felicitations by Dr. Renato J. Azzari, New York City, president, Medical Society of the State of New York. A symposium on pediatric problems is scheduled for Monday afternoon (Dr. Philip M. Stimson, New York City, moderator); on adult malignancies for Tuesday afternoon (Dr. Alton Ochsner, New Orleans, moderator); and on geriatrics for Wednesday afternoon (Dr. Duane M. Carr, Memphis, Tenn., moderator). Dr. G. Lombard Kelly, president emeritus, Medical College of Georgia, Augusta, will open the scientific program at 9:30 a. m. Monday with "Sex Counsel by the General Practitioner." At 11 a. m. Tuesday Dr. Ochsner will discuss "Cancer of the Lung." The annual banquet Tuesday, 7 p. m., will be a benefit for the American-Korean Foundation. Dr. Howard A. Rusk, New York City, chairman, board of directors of the foundation, will be the speaker. A postconvention cruise to Nassau will leave New York City Oct. 21 and return Oct. 28. Reservations are not limited to academy members. For information, write to the convention chairman, Dr. John Hunter Fuchs, 8712—132nd St., Richmond Hill 18, N. Y.

New York City

Tumor Clinic Conference.—Dr. George C. Escher, assistant attending physician, Memorial Center for Cancer and Allied Diseases, will present "Management of Advanced Mammary Carcinoma" at the tumor clinic conference in the Women's Pavilion, Harlem Hospital, Oct. 19, 10:45 a. m.

First Alfred P. Sloan Lecture.—The Sloan-Kettering Institute for Cancer Research announces the first annual Alfred P. Sloan Jr. Lecture, "Cancer, A Crossroads of Biology," to be delivered by Julian S. Huxley, D.Sc., Oct. 19, 8:30 p. m., at Hunter College Playhouse, 68th Street between Lexington and Park avenues.

Conferences on Drug Addiction.—Drug addiction will be discussed in nine monthly conferences at the Bellevue Hospital School of Nursing under the sponsorship of Riverside Hospital and the Welfare and Health Council of New York City. The series will start Oct. 20 with a discussion of "The Adolescent Addict—The Impact on the Community." Other topics include: "Narcotics—Traffic and Control," "The Family of the Addict," "Problem of Drug Withdrawal," "Problems of Patient Management in an Institutional Environment," "Rehabilitation of the Addict," and "The Addict After Discharge from the Institution." Dr. Kenneth W. Chapman, Washington, D. C., chief, neuropsychiatry branch, Public Health Service Division of Hospitals, will be one of the speakers. Riverside Hospital, a division of the city's department of hospitals, specializes in the study and treatment of the use of habit-forming drugs.

NORTH CAROLINA

Dr. Hart Honored.—Dr. Deryl Hart, Duke University School of Medicine, Durham, has completed 25 years as chairman of the department of surgery. On Oct. 20 his former residents will celebrate his anniversary at a banquet, at which time his portrait will be presented to the university. Dr. Wilburt C. Davison, dean of the school since its foundation in 1930, will be the speaker.

OHIO

Pediatric Symposium.—"The First Year of Life" will be the subject of the postgraduate fall symposium, to be presented at Saint Luke's Hospital, Cleveland, Oct. 21-22, with the cosponsorship of the Ohio Academy of General Practice, which will allow 13 hours' credit. Guest speakers will be Dr. John P. Caffey of the Babies Hospital, New York, and Dr. Warren E. Wheeler of Ohio State University College of Medicine, Columbus. Other speakers will be from Babies and Childrens Hospital, the Cleveland Clinic, and St. Luke's Hospital, Cleveland.

OREGON

M and R Conference.—The M and R Research Conference will be held at the University of Oregon Medical School, Portland, Oct. 20-21, under the joint sponsorship of the pediatric departments of the University of Oregon and University of Washington medical schools and under the chairmanship of Dr. Robert A. Aldrich, associate professor of pediatrics at the former school. About 20 biochemists and clinicians from various parts of the United States will discuss problems relating to "Iron Metabolism and Function." The meeting is open to all physicians and others interested.

Pediatric Research Society Meeting.—The annual meeting of the Western Society for Pediatric Research will be held in the library of the University of Oregon Medical School, Portland, Oct. 19, beginning at 9 a. m. Dr. Robert A. Aldrich will preside. Over 60 teaching and research pediatricians who live west of the Mississippi compose the membership of this group. A social hour and banquet is scheduled in the evening at the Columbia Athletic Club. The session is open to all physicians interested in the specialty.

TENNESSEE

Symposium at Vanderbilt on Newer Vitamins.—A Symposium on the Role of Some of the Newer Vitamins in Human Metabolism and Nutrition, made possible by a grant from the National Vitamin Foundation, will be held Oct. 20-21 in the amphitheater of Vanderbilt University School of Medicine, 21st Avenue South, Nashville. At 9:15 a. m. Thursday, Chancellor Harvie Branscomb will deliver greetings, followed by "The History of Vitamin B_6" by Dr. Paul Gyorgy, Philadelphia, and "Vitamin B_6 Deficiency in the Rhesus Monkey with Particular Reference to the Occurrence of Arteriosclerotic Lesions" by Drs. James F. Rinehart and Louis Greenberg, San Francisco. Discussion by Gladys A. Emerson, Ph.D., Rahway, N. J., and Norman Olsen, Ph.D., Nashville, will follow. At 10:50 a. m. presentation of "Experimental Neuropathology of Vitamin B_6 Deficiency" by Drs. Maurice Victor and Raymond D. Adams, Boston, will precede a paper on pyridoxine deficiency and convulsions in infancy by Dr. David B. Coursin, Lancaster, Pa., to be followed by discussion by Dr. Charles D. May, Iowa City. After luncheon, 12:30 p. m., Earle W. McHenry, Ph.D., Toronto, Canada, will consider "Metabolic Effects of Pyridoxine in Vivo" and Dr. Maximilian Wachstein, Brooklyn, N. Y., "Evidence for Abnormal Vitamin B_6 Metabolism in Pregnancy and Various Disease States," with discussion by Dr. William J. McGanity of Nashville. The closing presentations, 3:15 p. m., include "Metabolism of Vitamin B_6 in Human Beings" by Dr. Richard W. Vilter, Cincinnati (discussion: Dr. Henry Sebrell, New York), and "Some Interrelationships of Vitamin B_6 and Vitamin E" by Paul L. Day, Ph.D., and James S. Dinning, Ph.D., Little Rock, Ark. The Friday session, 9-10:30 a. m., includes the following presentations:

Studies on Tocopherol in Infants, Harry H. Gordon, Baltimore (discussion: Dr. Paul Gyorgy, Philadelphia).
Tocopheryl Hydroquinone and Muscle Dystrophy, Philip L. Harris, Ph.D., and Karl E. Mason, Ph.D., Rochester, N. Y.
Effects of Limited Tocopherol Intake in Human Males, Max K. Horwitt, Ph.D., Cecil C. Harvey, Ph.D., G. D. Duncan, and William C. Wilson, Elgin, Ill. (discussion: Grace A. Goldsmith, New Orleans).
Pantothenic Acid Deficiency Induced in Human Adults, William B. Bean, Iowa City (discussion: Dr. Beverly T. Towery, Nashville, and Floyd S. Daft, Ph.D., Bethesda, Md.).

Information may be obtained from the Department of Biochemistry, Vanderbilt University, Nashville, or the National Vitamin Foundation, Inc., 15 E. 58th St., New York 22.

VIRGINIA

State Medical Meeting in Richmond.—The Medical Society of Virginia will hold its 108th meeting at the Hotel Jefferson, Richmond, Oct. 16-19. The presidential address will be delivered by Dr. Carrington Williams, Richmond, Monday, 8:30 p. m. At 3:10 p. m. that day Dr. Richard B. Cattell, Boston, will outline "Advances in Pancreatic Surgery." An obstetric and gynecologic symposium is scheduled for 9:15 a. m. Tuesday and a panel on cardiac surgery for 10:30 a. m. Dr. Robert A. Ross, Chapel Hill, N. C., has been invited to discuss "Omissions and Commissions in Maternal Mortality" Tuesday morning. Tuesday afternoon the guest speaker, Dr. John deJ. Pemberton, Rochester, Minn., will present "Surgical Management of Nodular Goiter." At the banquet Dr. James P. King, Radford, will be installed as president. On Wednesday morning, 9:15 a. m., a panel discussion of the evaluation of laboratory procedures and their values will be presented. At 9:35 a. m. Dr. Martillus H. Todd, Coral Gables, Fla., will report about "Experiences with Bleeding Gastric and Duodenal Ulcer." A symposium on convulsions will be presented at 10:45 a. m. Dr. Williams will preside at a medicolegal session on professional liability insurance, 2 p. m., at which the guest speakers will be Ernest C. Fisher Jr., Aetna Casualty and Surety Company, Richmond, who will discuss malpractice; Robert G. Butcher, attorney, whose subject will be actions for malpractice; and A. Scott Anderson, president of the Richmond Bar Association, who will present "The Doctor as a Witness and His Obligation to the Court."

WISCONSIN

Circuit Programs at Three Locations.—The State Medical Society of Wisconsin will present the following program at the Elks Club, Rice Lake, Oct. 18; Mead Hotel, Wisconsin Rapids, Oct. 19; and the Elks Club, Appleton, Oct. 20:

Treatment of Systemic Arterial Hypertension, James W. Culbertson, Iowa City.
Surgical Emergencies in Children, Kenneth E. Lemmer, Madison.
Abortions and Chronic Diseases Related to OB, William C. Keettel, Iowa City.
Poison Control, Franklin J. Mellencamp, Milwaukee.

Five hours of formal teaching credit will be allowed members of the American Academy of General Practice for each meeting. The cost, $6, includes dinner and a "coffee break" in the middle of the afternoon. Reservations may be made through the State Medical Society of Wisconsin, Box 1109, Madison.

GENERAL

Noise Abatement Symposium.—The sixth annual National Noise Abatement Symposium will be held Oct. 20-21 at Armour Research Foundation of Illinois Institute of Technology, Chicago. The topics to be discussed will be "Noise in Industry (Case Histories)"; "Impact Noises"; and "Novel Methods of Noise Reduction."

Meeting of Neuropsychiatric Association.—The 31st annual convention of the Central Neuropsychiatric Association will be held at the Broadmoor Hotel, Colorado Springs, Colo., Oct. 21-22, under the presidency of Dr. Benjamin Boshes, Chicago, who will deliver an address at 2 p. m. Friday. Twenty-three speakers have been invited to participate in the sessions. The banquet will be held at 6:30 p. m. Friday. A mountain barbecue party will be held Oct. 20 at 5 p. m. There will be a prebarbecue cocktail party (compliments of Smith, Kline & French Pharmaceutical Company). Bus transportation will leave from the entrance of the hotel.

American Academy of Neurological Surgery.—The 17th annual meeting of the American Academy of Neurological Surgery will be held at the Homestead, Hot Springs, Va., Oct. 27-29. Dr. David L. Reeves, Santa Barbara, Calif., will deliver the presidential address, "The Neurosurgeon," on Friday. The scientific session Thursday, beginning at 9:15 a. m., will include presentations of unusual cases: (1) Intracranial Lipomas, Dr. Homer S. Swanson, Atlanta, Ga.; (2) An Unusual Oligodendroglioma, Drs. John R. Green and Harry F. Steelman, Phoenix, Ariz.; and (3) Otorrhea as a Complication of Removal of an Acoustic Neurinoma, A. Earl Walker, Baltimore. The sessions will include the following single author presentations by invited speakers:

Traumatic Intracerebral Hematoma: Review of 16 Successfully Treated Cases, Robert L. McLaurin, Cincinnati.
Therapy in Amyotrophic Lateral Sclerosis, William S. Fields, Houston, Texas.
Pathology of Cervical Whip Lash Injuries, Ernest W. Mack, Reno, Nev.
Alleviation of Experimental Facial Neuralgia by Trauma to the Gasserian Ganglion, Robert B. King, St. Louis.

Prize for Medical Research.—The Joseph A. Capps Prize for Medical Research, founded by Dr. and Mrs. Edwin R. LeCount, is being offered by the Institute of Medicine of Chicago as an annual prize of $300 for the most meritorious investigation in medicine or in the specialties of medicine. The investigation may be also in the fundamental sciences, provided the work has a definite bearing on some medical problem. Competition for 1955 is open to graduates of Chicago medical schools who completed their internship or one year of laboratory work within a period of five years before Jan. 1, 1955, excluding their terms of service in the armed forces. Manuscripts must be submitted to the Secretary of the Institute of Medicine of Chicago, 86 E. Randolph St., Chicago 1, not later than Dec. 31, 1955. The manuscript of the prize paper, as submitted, will become the property of the Institute of Medicine of Chicago.

Correspondence School for Shut-In Children.—The Calvert School, Baltimore, an unendowed nonprofit institution that for almost 50 years has given an elementary school education to children who cannot attend regular schools, provides education by mail for home-bound children throughout the United States. Calvert's courses (from kindergarten through the ninth grade) are accredited by the state of Maryland. Children with heart conditions make up about 20% of Calvert's shut-in students; poliomyelitis patients about 15%; chronic asthma sufferers about 10%; and those with eye, ear, and speech defects about 15%. Muscular dystrophy, cerebral palsy, diabetes, and hemophilia are among the other causative factors affecting Calvert's home-bound students. Although its home-study courses are laid out for 160 "school days," Calvert suits the speed of learning to the capacity of the shut-in child. Parents receive all necessary directions for supervising the home study.

Nutrition Grants.—The National Vitamin Foundation, Inc., announces 16 new grants to American universities and medical centers, totaling $70,766. The foundation gives grants-in-aid for research semiannually throughout the United States and abroad. Recipients of the new grants include the following physicians: Albert B. Eisenstein, St. Louis, for studies of the relationship of pantothenic acid to adrenocortical hormone secretion; George J. Gabuzda, Cleveland, for studies of the metabolism and interrelationship of folic acid, citrovorum factor, and ascorbic acid; Irving P. Graef, New York, for studies of the effect of pantothenic acid deficiency in various disease states; G. Watson James III, Richmond, Va., for studies of vitamin B_{12} growth activity of P. stipitata in human leukemia; and A. Leonard Luhby, New York, for studies of the evaluation of urinary formamido-L-glutamic acid excretion as a clinical test for folic acid undernutrition.

Meeting of Dietetic Association.—The 38th annual meeting of the American Dietetic Association will be held in St. Louis Oct. 18-21. Physicians participating will include:

Carl V. Moore, St. Louis, Absorption of Iron from Enriched Bread and Other Foods.
Morris J. Fogelman, Dallas, Texas, Food Intake and Hypnosis in Surgical Diseases.
Jeffrey H. Fryer, Ithaca, N. Y., Advances in Nutrition.
James M. Hundley, Bethesda, Md., Obesity—A U. S. Problem.
Grace A. Goldsmith, New Orleans, Niacin Deficiency in Man.
Josef Warkany, Cincinnati, Endemic Cretinism in Europe.

The Maternal and Infant Health Session will be opened by Lois Murphy, Ph.D., consultant of the department of child psychiatry of the Menninger Foundation, Topeka, Kan., who will discuss "Psychological Aspects of Infant and Child Feeding." "Newer Findings on Amino Acids" will be the topic of Conrad A. Elvehjem, Ph.D., dean of the Graduate School of the University of Wisconsin, Madison, during the session on current nutrition research.

Cardiovascular Disease.—According to the American Heart Association, deaths from diseases of the heart and blood vessels decreased slightly in the United States during 1954, although these diseases continue to outrank all others as America's leading cause of death and were responsible for 52.3% of all deaths in 1954. Figures provided by the National Office of Vital Statistics show that deaths from disease of the cardiovascular system dropped in 1954 to 773,980 (480.2 per 100,000 population) from a high of 794,120 (501.6 per 100,000) reached in 1953. This drop paralleled a drop in the U. S. death totals from 1,518,600 in 1953 to 1,481,000 last year. Improvement in the cardiovascular death rate is attributed by the association to a sharp drop in the incidence of influenza and pneumonia last year as compared with 1953, the first two months of which were marked by a severe and widespread influenza outbreak. No significant change occurred in 1954 in the number or rate of deaths from arteriosclerotic heart disease, including coronary disease. In the under 65 age group in 1954, cardiovascular diseases took 232,750 lives, or more than double the number claimed in this age group by cancer, second leading cause of death.

Manual for Handicapped Swimmers.—The American Red Cross has published an instructor's manual, "Swimming for the Handicapped," based on experience in a program started in 1945, when the Red Cross cooperated with the armed forces to provide swimming instruction for handicapped veterans and servicemen. Prepared with the assistance of physicians, physical therapists, physical education experts, and water safety instructors, the manual includes information that outlines the general physiological and psychological values of swimming, lists the facilities and equipment needed, and provides explanatory information that will help instructors better understand and teach the handicapped. The detailed section on specific programs for various conditions covers temporary orthopedic disabilities, permanent disabilities due to loss of body parts, paralysis due to injury or disease, permanent disabilities due to heart condition, permanent disabilities due to sight and hearing difficulties, and disabilities due to mental illness. Information concerning the program and the manual can be obtained from local Red Cross chapters or from area offices located in Alexandria, Va.; Atlanta, Ga.; St. Louis; and San Francisco.

National Safety Congress.—The 43rd National Safety Congress and Exposition will convene in Chicago Oct. 17-21 at the Conrad Hilton Hotel. A symposium, "Effective Utilization of the Disabled Employee in Industry," has been scheduled for Tuesday morning; a program, "Atomic Energy Is in Industry," for Wednesday morning; and a symposium, "Public Health Aspects of Home Safety," for 2 p. m. At 12:15 p. m. Wednesday in the Williford Room "B" the American Medical Association, through its Committee on Pesticides and Committee on Toxicology, will be awarded a national home safety Certificate of Commendation for exceptional public service in the prevention of home accidents during the year 1954-1955. Presentations by physicians will include "Medical Services in a Small Plant" by Dr. Kozme F. Kapov, Chicago, Monday, 2:30 p. m., at the Congress Hotel; "Back Injuries" by Dr. Matt A. Connell, Picher, Okla., Monday, 3:30 p. m., Congress Hotel; "Radiation in Industry—Nursing and Health Aspects" by Dr. Eugene L. Walsh, Chicago, Wednesday, 10:45 a. m., Conrad Hilton Hotel; "Health Problems in the Printing Plant" by Dr. Gradie R. Rowntree, Louisville, Ky., Monday, 3:20 p. m., Conrad Hilton Hotel; "Eyes—Facts and Fallacies" by Dr. Hedwig S. Kuhn, Hammond, Ind., Thursday, 2 p. m., Conrad Hilton Hotel; and "Eye Safety in the Halls of Ivy" by Dr. Kuhn, Thursday, 10:25 a. m., Morrison Hotel.

Medicodental Symposium.—The Fourth Naval District will present the sixth annual Military Medico-Dental Symposium for all armed forces of the United States Oct. 17-22 at the U. S. Naval Hospital, Pattison Avenue, Philadelphia. Members of the nursing professions, students, interns, residents, and hospital administrators also are cordially invited. The first general session will hear discussed "The Expanding Horizons of Military Medicine" by Dr. Elmer Hess, Erie, Pa., President, American Medical Association, and Major Gen. Dan C. Ogle, surgeon general, U. S. A. F. Dr. Joseph Stokes Jr., Philadelphia, will moderate a discussion on virus diseases Tuesday, during which "Infectious Hepatitis" will be presented by Dr. W. Paul Havens Jr.; "Poliomyelitis" by Dr. Lewis L. Coriell; and "Diagnosis of Viral Diseases" by Dr. Klaus Hummeler, all of Philadelphia. A clinicopathological conference will be presented Wednesday by Dr. Lorenz E. Zimmerman, Washington, D. C., and Francis H. Adler, Philadelphia. The second general session, Thursday, will hear a panel discussion on civil defense conducted by Commander Paul B. Hartenstein, U. S. N. R. (Ret.), executive director, Philadelphia Civil Defense Council. The joint session on medicine and psychiatry Friday will hear a discussion on chronic alcoholism, drug addiction, and suicide, moderated by Rear Adm. Richard A. Kern, M. C., U. S. N. R. (Ret.), professor of medicine, Temple University School of Medicine, Philadelphia. The section on urology will have a discussion Friday on renal calculi. The Navy-Penn football game will be held at Franklin Field, University of Pennsylvania, Saturday (tickets, $4).

Meeting of Life Insurance Medical Directors.—The Association of Life Insurance Medical Directors of America will hold its 64th annual meeting at the Hotel Statler, New York, Oct. 19-21, under the presidency of Dr. Richard L. Willis, New York. The half-day session Wednesday will consist of a business meeting, followed by "Mortality Studies of Isolated Electrocardiographic T-Wave Changes" by Dr. Charles E. Kiessling, Newark, N. J., Dr. Royal S. Schaaf, Newark, N. J., and Annie Mary Lyle, of the Prudential Insurance Company of America, and "The Development and Treatment of Hypertensive Disease" by Dr. Edgar A. Hines Jr., Rochester, Minn. Thursday morning "Substandard Accident and Sickness Insurance" will be presented by Dr. William H. Scoins, Fort Wayne, Ind., of the Lincoln National Life Insurance Company; "Clinical Evaluation of the Commoner Hepatic Disorders" by Dr. Franklin M. Hanger, Columbia University College of Physicians and Surgeons, New York; and "Coronary Artery Disease" by Dr. Samuel A. Levine, Harvard Medical School, Boston. In the afternoon "Chemical Treatment of Cancer" will be considered by Dr. Joseph H. Burchenal, Cornell University Medical College, New York, and "Prognosis in Peptic Ulcer Disease" by Dr. Henry L. Bockus, University of Pennsylvania Graduate School of Medicine, Philadelphia. The banquet will be held at 6 p. m. The following program is scheduled for Friday morning:

The Altered Prognosis in Diabetes Mellitus, Herbert Pollack, New York.
Present Concepts of Arteriosclerosis, William Dock, Brooklyn, N. Y.
Discussion of the Recent Impairment Study of the Society of Actuaries, Mr. Andrew C. Webster, New York.

Meeting of Heart Association.—The 31st annual meeting of the American Heart Association will convene in New Orleans Oct. 22-28 under the presidency of Dr. E. Cowles Andrus, Baltimore. The scientific sessions and the special community service and rheumatic fever programs will be held in the Municipal Auditorium, and other events, including the meetings of the assembly and of the staff conference of heart associations, will be at the Jung Hotel. This year's scientific sessions will be the first ever held independently of any major medical gathering. A panel on aneurysms of the aorta will be presented Saturday morning. In the afternoon Dr. George A. Perera, New York, will deliver the Lewis A. Conner Memorial Lecture, "Digital Rheoplethysmography." The George E. Brown Memorial Lecture on primary hypertension will be given Sunday morning by Dr. George E. Burch, New Orleans, as will the program of the Council on Community Service and Education on body weight and heart disease. A panel on electrolyte disturbances in cardiac and renal diseases and a program on heart disease and rehabilitation are scheduled for Sunday afternoon. Monday morning will be devoted to a joint program of the councils on rheumatic fever and congenital heart disease and on community service and education, which will deal with prevention of rheumatic fever and the cardiac child in the schools. In the afternoon a panel, "The Role of Hemodynamic Data in Determining Operability," will be presented. Among the social events will be the annual dinner dance of the association, Sunday evening, at which the presidential address will be delivered and the 1955 Gold Heart and Howard Blakeslee awards will be made. An eight day medical tour to Mexico has been arranged, starting from New Orleans on Thursday. Included will be a series of special cardiological programs in Mexico City, arranged by the National Institute of Cardiology.

FOREIGN

Fluorination Abroad.—Cairo, Egypt, with a population of more than 2 million, has announced plans to fluorinate its public water supply. Other countries, in addition to the United States, that have fluorination of some municipal water supplies include: Brazil, Canada, Chile, Colombia, Germany, Holland, Japan, New Zealand, Sweden, and Switzerland.

Prize for Trachoma Essay.—For the fourth time, the Chibret Gold medal for works on the pathology and treatment of trachoma will be awarded during the general assembly of the Anti-Trachoma League, which will be held in Paris, France, in 1956. The paper may deal with any of the following aspects: clinical, social, preventive, medical therapeutics, or surgical therapeutics. It must be written in French, have a maximum of 30 typewritten pages, be presented in triplicate, accompanied by an abstract of two pages in French and so far as possible in English, Italian, and Spanish, and be submitted before Jan. 1, 1956, to the general secretary of the league, Dr. Jean Sedan, 94, rue Silvabelle, Marseilles, Telephone, Dr 37-55.

International Colloquium on Chlorpromazine.—An International Colloquium on Chlorpromazine and the Neuroleptic Agents in Psychotherapy will be held at the Clinique des Maladies Mentales et de l'Encephale, Hôpital Sainte-Anne, Paris, France, Oct. 20-22. The aim of the meeting is to bring together not only those who, in their various countries, have made a special study of these new treatments but also all specialists who are particularly interested. Specialists from Argentina, Austria, Belgium, Brazil, Canada, Colombia, Cuba, England, Egypt, Germany, Greece, Holland, Italy, Lebanon, Luxemburg, Mexico, Peru, Portugal, Spain, Sweden, Switzerland, Turkey, the United States, and Venezuela, as well as the French Union, are expected to attend. The program includes: methods of administration; posology and length of treatments; indications and contraindications of the different methods; uses in connection with other forms of psychiatric treatment; accidents and caution; chlorpromazine and reserpine; neurophysiological and psychophysiological effects; and a hypothesis concerning modes of action. Information may be obtained from Dr. Pierre Deniker, Clinique de la Faculte, 1, rue Cabanis, Paris 14eme.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

1956 Annual Meeting, Chicago, June 11-15.

1956 Clinical Meeting, Seattle, Nov. 27-30.

1957 Annual Meeting, New York, June 3-7.

National Medical Public Relations Conference, Hotel Statler, Boston, Nov. 28. Mr. Leo F. Brown, 535 N. Dearborn St., Chicago 10, Director.

American Academy of Dermatology and Syphilology, Palmer House, Chicago, Dec. 3-8. Dr. James R. Webster, 55 East Washington St., Chicago 2, Secretary.

American Academy of Neurological Surgery, The Homestead, Hot Springs, Va., Oct. 27-29. Dr. Eben Alexander Jr., Bowman Gray School of Medicine, Winston-Salem, N. C., Secretary.

American Academy of Obstetrics and Gynecology, Conrad Hilton Hotel, Chicago, Dec. 13. Dr. C. Paul Hodgkinson, 116 South Michigan Blvd., Chicago, Secretary.

American Association of Blood Banks, Palmer House, Chicago, Nov. 19-21. Miss Marjorie Saunders, 3707 Gaston Ave., Dallas 10, Texas, Secretary.

American Association of Medical Clinics, Curtis Hotel, Minneapolis, Nov. 4-6. Dr. Edwin P. Jordan, Box 58, Charlottesville, Va., Executive Director.

American Association for the Surgery of Trauma, Drake Hotel, Chicago, Oct. 27-29. Dr. James K. Stack, 700 N. Michigan Blvd., Chicago 11, Secretary.

American Clinical and Climatological Association, The Homestead, Hot Springs, Va., Oct. 31-Nov. 2. Dr. M. N. Fulton, 124 Waterman St., Providence 6, R. I., Secretary.

American College of Anesthesiologists, Hotel Statler, Boston, Nov 4-5. Mr. John H. Hunt, 188 West Randolph St., Chicago 1, Executive Secretary.

American College of Cardiology Interim Meeting, Hotel Claridge, Memphis, Tenn., Nov. 10-12. Dr. Philip Reichert, Empire State Bldg., New York 1, Secretary.

American College of Gastroenterology, Hotel Shoreland, Chicago, Oct. 24-26. Dr. Joseph Shaiken, 33 West 60th St., New York 23, Secretary

American College of Surgeons, Conrad-Hilton Hotel, Chicago, Oct. 31-Nov. 4. Dr. Michael L. Mason, 40 East Erie St., Chicago 11, Secretary.

American Dental Association, San Francisco, Oct. 17-20. Dr. Harold Hillenbrand, 222 East Superior St., Chicago 11, General Secretary.

American Heart Association, Yung Hotel, New Orleans, Oct. 22-26. Mr. Irving Hexter, 44 East 23d St., New York 10, Secretary.

American Medical Women's Association, Board Meeting, Netherlands-Plaza Hotel, Cincinnati, Nov. 11-13. Miss Lillian T. Majally, 1790 Broadway, New York 19, Executive Secretary.

American Public Health Association, Muehlebach Hotel and Municipal Auditorium, Kansas City, Mo., Nov. 14-18. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

American School Health Association, Hotel President, Kansas City, Mo., Nov. 14-18. Dr. A. O. DeWeese, 515 East Main St., Kent, Ohio, Secretary.

American Society of Anesthesiologists, Hotel Statler, Boston, Oct. 29-Nov. 3. Dr. J Earl Remlinger Jr., Room 1101, 188 W. Randolph St., Chicago 1, Secretary.

American Society for the Study of Arteriosclerosis, Hotel Sheraton, Chicago, Nov. 6-7. Dr. O. J. Pollak, P.O. Box 228, Dover, Del., Secretary.

American Society of Tropical Medicine and Hygiene, Somerset Hotel, Boston, Nov. 2-5. Dr. John E. Larsh Jr., Dept. of Parasitology, School of Public Health, Chapel Hill, N. C., Secretary.

Association of American Medical Colleges, New Ocean House, Swampscott, Mass., Oct. 24-26. Dr. Dean F. Smiley, 185 N. Wabash Ave., Chicago 1, Secretary.

Association of Life Insurance Medical Directors of America, Hotel Statler, New York, Oct. 19-21. Dr. Henry B. Kirkland, P. O. Box 594, Newark, N. J., Secretary.

Association of Military Surgeons of the U. S., Hotel Statler, Washington, D. C., Nov. 7-9. Colonel Robert E. Bitner, 1726 I St. N.W., Washington 6, D. C., Secretary.

Association for Research in Nervous and Mental Diseases, Hotel Roosevelt, New York, Dec. 9-10. Dr. Clarence C. Hare, 710 West 168th St., New York 32, Secretary.

Association of State and Territorial Health Officers, Hotel Washington, Washington, D. C., Nov. 6-12. Dr. Franklin D. Yoder, State Board of Health, Cheyenne, Wyo., Secretary.

Central Neuropsychiatric Association, The Broadmoor, Colorado Springs, Colo., Oct. 20-22. Dr. Hamilton Ford, 112 North Boulevard, Galveston, Tex., Secretary.

Central Society for Clinical Research, Drake Hotel, Chicago, Nov. 4-5. Dr. Robert H. Ebert, 950 East 59th St., Chicago 37, Secretary.

Congress of Neurological Surgeons, Hotel Statler, Los Angeles, Oct. 27-29. Dr. Philip D. Gordy, 1007 Delaware Ave., Wilmington, Del., Secretary.

Delaware, Medical Society of, Delaware Academy of Medicine, Wilmington, Oct. 17-18. Dr. Norman L. Cannon, 621 Delaware Ave., Wilmington, Secretary.

Eastern Section, American Federation for Clinical Research, Hotel Warwick and College of Physician's Building, Philadelphia, Dec. 2-3. Dr. Charles R. Shuman, Temple Univ. Hospital, Broad and Ontario Sts., Philadelphia 40, Chairman.

Gerontological Society, Sheraton-Belvedere Hotel, Baltimore, Oct. 27-29. Dr. Nathan W. Shock, Baltimore City Hospitals, Baltimore 24, Secretary.

Gulf Coast Clinical Society, Pensacola, Fla., Oct. 27-28. Dr. Barkley Beidleman, 1750 N. Palafox St., Pensacola, Fla., Secretary.

Indiana State Medical Association, French Lick Springs Hotel, French Lick, Oct. 16-19. Mr. James A. Waggener, 23 East Ohio St., Indianapolis 4, Executive Secretary.

Inter-Society Cytology Council, Statler Hotel, Cleveland, Nov. 11-12. Dr. Paul F. Fletcher, 634 N. Grand Blvd., St. Louis 3, Secretary.

Interstate Post Graduate Medical Association of North America, Municipal Auditorium, Milwaukee, Nov. 14-17. Mr. Roy T. Ragatz, 207 Gay Bldg., Madison 3, Wis., Executive Director.

Medical Society Executives Conference, Parker House, Boston, Nov. 27. Mr. H. Martin Baker, 1102 South Hillside, Witchita 17, Kansas, Secretary.

Midwestern Section of American Federation for Clinical Research, Thorne Hall, Northwestern University, and Drake Hotel, Chicago, Nov. 3. Dr. Robert J. Glaser, Barnes Hospital, St. Louis 10, Secretary.

National Association for Mental Health, Indianapolis, Nov. 4-6. Mr. Robert M. Heininger, 1790 Broadway, New York 19, Director.

New England Health Education Association, Boston, Dec. 2. Miss Wyntha Tompkins, Middlesex Health Association, Essex, Mass., Secretary.

Oklahoma City Clinical Society Conference, Oklahoma City, Oct. 24-27. Dr. Charles E. Leonard, 512 Medical Arts Bldg., Oklahoma City 2, Secretary.

Omaha Mid-West *Clinical Society*, Hotel Paxton, Omaha, Oct. 24-27. Mrs. Anne K. Ramsey, 1031 Medical Arts Bldg., Omaha 2, Executive Secretary.

Puerto Rico Medical Association, Santurce, Dec. 7-11. Dr. Luis R. Guzman-Lopez, Box 9111, Santurce, Secretary.

Regional Meetings, American College of Physicians:
Louisville, Ky., Nov. 5. Dr. Sam A. Overstreet, 332 West Broadway, Louisville, Ky., Governor.
Newark, N. J., Nov. 9. Dr. Edward C. Klein Jr., 6 S. Kingsman Rd., *South Orange, N. J., Governor.*
Detroit, Dec. 3. Dr. H. Marvin Pollard, 1313 East Ann St., Ann Arbor, Mich., Governor.
Hot Springs, Ark., Dec. 3. Dr. A. A. Blair, 100 S. 14th St., Ft. Smith, Ark., Governor.
Winston-Salem, N. C., Dec. 8. Dr. Elbert Persons, Duke Hospital, Durham, N. C., Governor.

Society of Clinical Surgery, Hotel Roosevelt, New Orleans, Nov. 11-12. Dr. Frank F. Allbritten Jr., University of Kansas Medical Center, Kansas City, Mo., Secretary.

Southern Medical Association, *Shamrock Hotel, Houston, Texas, Nov. 14-17. Mr. V. O. Foster, 1020 Empire Bldg., Birmingham 3, Ala.,* Secretary-Manager.

Southern Society of Cancer Cytology, Houston, Texas, Nov. 14-17. Dr. J. Ernest Ayre, 1155 N.W. 14th St., Miami, Fla., Secretary.

Southern Surgical Association, The Homestead, Hot Springs, Va., Dec. 6-8. Dr. George G. Finney, 2947 St. Paul St., Baltimore 18, Secretary.

World Congress on Fertility and Sterility, Naples, Italy, May 18-26, 1956. For information address: Prof. G. Tesauro, S. Andrea della Dame, 19, Naples, Italy.

EXAMINATIONS AND LICENSURE

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Oral.* New York City, Oct. 23-27. *Written.* Various locations in United States and Canada, July 20, 1956. Final date for filing application is Jan. 20. Sec., Dr. Curtiss B. Hickcox, 80 Seymour St., Hartford 15.

American board of Internal Medicine: *Oral.* Chicago, Nov. 30-Dec. 1. *Subspecialties. Cardiovascular Disease.* Chicago, Nov. 30. The closing date for acceptance of application for gastroenterology was Feb. 1, and for cardiovascular disease the closing date was June 1. Exec. Sec., Dr. William A. Werrell, 1 West Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* New Haven, November. Oral examinations given in Spring and Fall. Final date for filing application for the Spring examination was October 1; for the Fall examination April 1. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology: *Written Examination and submission of Case Reports. Part I.* Various locations in United States and Canada, and military centers outside of the Continental United States, Feb. 3, 1956. Final date for filing application was Oct. 1. *Oral and Pathological Examinations. Part II.* Chicago, May 11-20, 1956. Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: Written. January 24-26, 1956. *Practical Examination.* San Francisco, June 18-21, St. Louis, Oct. 20-25. Applications for 1957 written examination must be filed before July 1, 1956. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland 9, Maine.

American Board of Orthopaedic Surgery: *Oral.* Jan. 26-27. Final date for filing application was Aug. 15. *Part I. Oral and written.* Various centers, April 1956. Final date for filing application is Nov. 30. Sec., Dr. Harold A. Sofield, 116 South Michigan Ave., Chicago 3.

American Board of Pediatrics: *Oral.* Washington, D. C., Dec. 2-4. Admin. Sec., Mrs. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Physical Medicine and Rehabilitation. *Parts I and II.* Chicago, June 16-17. Sec., Dr. Earl C. Elkins, 200 First St., S. W., Rochester, Minn.

American Board of Preventive Medicine: *Certification in Public Health.* Kansas City, Mo., Nov. 10-12. Sec.-Treas., Dr. Ernest L. Stebbins, 615 N. Wolfe St., Baltimore 5.

American Board of Psychiatry and Neurology: San Francisco, Oct. 17-18; New York City, December, Philadelphia, April 16-18, 1956. Sec., Dr. David A. Boyd, 102-110 Second Ave. S.W., Rochester, Minn.

American Board of Radiology: Chicago, Dec. 4. Final date for filing applications for the fall examination was July 1. Candidates who will complete their training by Dec. 31 will be eligible to appear for this examination. Sec., Dr. B. R. Kirklin, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Part I.* Centers throughout the United States, in Europe and in the Far East, Oct. 26 and March 28. Closing date for the October examination was July 1 and for the March examination is December 1. *Part II.* Chicago, Oct. 27-28; New York City, Nov. 14-15; St. Louis, Dec. 12-13; New Orleans, Jan. 16-17; Los Angeles, Feb. 13-14; San Francisco, Feb. 16-17; Durham, Mar. 12-13; Boston, May 14-15 and Philadelphia, June 4-5. Sec., Dr. John B. Flick, 255 S. Fifteenth St., Philadelphia 2.

MAGAZINE–TELEVISION REPORT

The following list of current medical articles in mass-circulation magazines and forthcoming network television programs on medical subjects is published each week only for the information of readers of The Journal. *Unless specifically stated, the American Medical Association neither approves nor disapproves of the articles and programs reported.*

TELEVISION

Sunday, Oct. 16, 1955

NBC-TV, 2 p. m. EDT. "American Inventory." A dramatization entitled "The Ounce and the Pound" points up the need for developing preventive measures against mental illness.

Monday, Oct. 17, 1955

ABC-TV, 9:30 p. m. EDT. "Medical Horizons" visits the University of Pennsylvania School of Medicine for a report on the training of a medical student.

Wednesday, Oct. 19, 1955

NBC-TV, 11:30 a. m. EDT. "Medical and Health News" with Howard Whitman, a regular segment of the "Home" show.

Monday, Oct. 24, 1955

NBC-TV, 9 p. m. EDT. "Medic," in a story titled "When I Was Young," tells of a woman going through menopause and explains medicine's new methods of dealing with it.

ABC-TV, 9:30 p. m. EDT. "Medical Horizons" shows the rigorous activities of residency training in a presentation from Johns Hopkins Hospital in Baltimore.

MAGAZINES

Look, Nov. 1, 1955 (On newsstands Oct. 18)

"Why Doctors Face So Many Law Suits," by Louis J. Regan, M.D., LL.B.

The author points out that the increased number of malpractice suits against doctors do not "reflect a lessening of efficiency or training or dedication on the part of doctors." He says: "In terms of the many millions of medical cases which are treated each year by the nation's physicians, there has been no increase in *actual* malpractice; there has been, however, a staggering increase in the number of malpractice *claims.*" The article includes an outline of a doctor's legal obligations, a summary of what medical societies are doing to prevent or reduce malpractice cases, and "advice" to patients that, if followed, would cut down the number of unjustified claims.

Prairie Farmer, Oct. 1, 1955

"More Doctors for Rural Communities," by Paul C. Johnson

Ten years ago farm folks were very much worried about the shortage of rural doctors, but this problem is "well on the way to being solved." Mr. Johnson, the editor of *Prairie Farmer,* attributes the progress to "a great surge of interest in rural health by the communities themselves" and "direct attack on the problem . . . by the doctors, working through the American Medical Association and state and county medical societies." The article tells in detail about the work of the American Medical Association's Council on Rural Health.

Harper's Magazine, October, 1955

"Alvarez: Everybody's Family Doctor," by Greer Williams

A profile of Walter Clement Alvarez, M.D., former Mayo Clinic physician who now devotes his time to writing and editing.

The American Weekly, Oct. 16, 1955

"The Sick Mind," by John Gunther

Patients at Creedmoor State Hospital, Queens Village, N. Y., are kept busy with recreation and occupational therapy as a part of their treatment for mental illness.

Saturday Evening Post, Oct. 8, 1955

"Good News for Disabled Wage Earners," by Richard Carter

"With parallel spurts in activity on the part of industry and labor, it is entirely possible that, within the next decade, America's skilled working men and women, its most precious resource, will all be protected by rehabilitation programs." The article reports on efforts of private insurance companies, workmen's compensation boards, and labor organizations to rehabilitate injured workers.

Ladies' Home Journal, October, 1955

"New Hope for Scarred Skins," by Dawn Crowell Norman

Personal experience story of a housewife who had surgical planing treatment for her scarred face. Accompanying the article is a statement by George M. Lewis, M.D., president, American Board of Dermatology and Syphilology, that gives scientific information on the procedure and estimates the cost.

DEATHS

Strong, Robert Alexander, Pass Christian, Miss.; born in New Orleans Nov. 17, 1884; Medical Department of Tulane University of Louisiana, New Orleans, 1907; from 1929 to 1944 professor and head of the department of pediatrics at his alma mater, where he joined the faculty in 1912 as assistant in diseases of children and later became instructor in diseases of children, lecturer and instructor in diseases of children, assistant professor of pediatrics, clinical professor of pediatrics, and professor of clinical pediatrics, resigning at the close of session 1922-1923; from 1929 to 1944 he was professor of pediatrics, faculty of the Graduate School of Medicine of Tulane University, and from 1937 to 1944 was professor of pediatrics in the department of graduate medical studies; specialist certified by the American Board of Pediatrics; past vice-president of the Mississippi State Medical Association and the Association of American Teachers of the Diseases of Children; past-president of the Louisiana State Pediatric Society; chairman of the section on pediatrics of the Southern Medical Association from 1926 to 1927; charter member and fellow of the American Academy of Pediatrics and from 1930 to 1940 Louisiana state chairman for region 2; charter member and past-president of the Aero Medical Association of the United States; member of the board of administrators, New Orleans Child Guidance Clinic, 1930-1932; served during World Wars I and II; formerly on the staffs of the Charity Hospital, Presbyterian Hospital, Touro Infirmary, and the Baptist Hospital; editor-in-chief of the *Journal of Aviation Medicine* when it was organized in 1930 and served as a member of the advisory editorial board; served as editor of the *International Medical Digest,* on the board of editorial collaborators of the *Archives of Pediatrics,* and as a member of the advisory editorial board, *American Journal of Syphilis* and *Journal of Pediatrics;* at one time editor-in-chief, *Orleans Parish Medical Society Bulletin;* for many years member of the editorial board of *Advances in Pediatrics;* author of numerous articles in various medical journals; died Aug. 7, aged 70.

Key, John Albert ⊕ St. Louis; born in Jackson, Miss., April 21, 1890; Johns Hopkins University School of Medicine, Baltimore, 1918; interned at the Massachusetts General Hospital and the Children's Hospital in Boston; in 1921-1922 instructor of applied physiology at Harvard Medical School, Boston; served as professor of clinical orthopedic surgery at Washington University School of Medicine; specialist certified by the American Board of Orthopaedic Surgery; vice-chairman, Section on Orthopedic Surgery, 1939-1940, and chairman, 1940-1941, of the American Medical Association; past-president of the American Orthopaedic Association; member of the American Surgical Association, Clinical Orthopaedic Society, Southern Surgical Association, and the American Academy of Orthopaedic Society; fellow of the American College of Surgeons; served during World War I; on the staffs of the Barnes, St. Louis Children's, St. Louis City and Jewish hospitals, and the Shriners Hospital for Crippled Children; joint author with Dr. H. Earle Conwell of "Management of Fractures, Dislocations and Sprains"; died at his summer home in Wesco, Mo., Aug. 6, aged 65, of coronary thrombosis.

Taylor, Malcolm Cushing ⊕ Cincinnati; born in Boston June 5, 1901; Harvard Medical School, Boston, 1929; specialist certified by the American Board of Psychiatry and Neurology; served in the U. S. Army Air Force from 1942 to 1946; fellow of the American Psychiatric Association; charter member of the New Jersey Neuropsychiatric Society; member of the New England Society of Psychiatry; assistant physician at the New Jersey State Hospital in Greystone Park, N. J., from 1931 to 1939; assistant in neurology at the Vanderbilt Clinic, Presbyterian Hospital, New York City, from 1939 to 1942; consultant in neuropsychiatry at the Morristown Memorial Hospital in Morristown, N. J., from 1939 to 1942; senior psychiatrist at the Columbus (Ohio) State Hospital, 1947-1948; clinical director of the Arizona State Hospital in Phoenix, Ariz., 1948-1949, when he became clinical director of the Norwich (Conn.) State Hospital, serving from 1949 to May, 1955; since May 16, 1955, assistant superintendent of the Rollman Receiving Hospital; died Aug. 22, aged 54, of coronary occlusion.

Randel, Henry Andreas ⊕ Fresno, Calif.; born in Berwick, Pa., April 16, 1902; Northwestern University Medical School, 1929; specialist certified by the American Board of Internal Medicine; served as chairman of the council on rural health of the California Medical Association; member of the House of Delegates of the American Medical Association in 1953 and since 1954 a member of the Council on Rural Health; fellow of the American College of Chest Physicians; member of the National Tuberculosis Association, the American Trudeau Society, and the American Heart Association; served as president of the Fresno County Tuberculosis Association, of which he was director for 12 years; on the staffs of the Fresno Community Hospital, General Hospital of Fresno County, where he interned, and St. Agnes Hospital; died in Morro Bay in August, aged 53.

Kagan, Solomon R., Boston; born in Orany, Lithuania, Dec. 15, 1889; an ordained rabbi; University of Dorpat Faculty of Medicine, Russia, 1917; the next five years he served as government physician in the Crimea and as health officer in Rostov-on-the Don; came to the United States in 1922; practiced medicine in Springfield and then in Roxbury, Mass.; in 1929 appointed a member of the staff of the Jewish Memorial Hospital in Roxbury; held honorary membership in the Eugene Field Society and in the Israel Society of Medical History; author of "Researches in Hebrew Literature," "American Jewish Physicians of Note," "Jewish Contributions to Medicine in America," "Jewish Medicine," "Life and Letters of Fielding H. Garrison," and others; formerly associate editor of "Medical Leaves"; editor of the "Victor Robinson Memorial Volume" and of the "Abraham Levinson Anniversary Volume"; a member of the editorial board of *Clinical Medicine;* associate editor of *The Medical Way;* died in the Beth Israel Hospital July 28, aged 65, of cerebral vascular accident.

Yaskin, Joseph Charles ⊕ Philadelphia; born Aug. 1, 1891; Medico-Chirurgical College of Philadelphia, 1914; professor of neurology at the Graduate School of Medicine of the University of Pennsylvania and assistant professor of psychiatry at the University of Pennsylvania School of Medicine; specialist certified by the American Board of Psychiatry and Neurology; member of the American Neurological Association, American Psychiatric Association, and the Association for Research in Nervous and Mental Diseases; past-president of the Philadelphia Neurological Society and the Philadelphia Psychiatric Society; served during World War I; received citations from two Presidents for his work with the Selective Service System; psychiatric consultant to the Army, Navy, and Veterans Administration; on the staffs of the Philadelphia Psychiatric, Philadelphia General, and Pennsylvania hospitals and the Graduate Hospital, where he died Aug. 10, aged 64, of coronary thrombosis.

Baker, May Davis, Rutledge, Pa.; Howard University College of Medicine, Washington, D. C., 1896; member of the Medical Society of the District of Columbia; died Aug. 22, aged 89, of arteriosclerotic heart disease.

Barrett, Frederick J., Kenmore, N. Y.; University of Buffalo School of Medicine, 1897; formerly practiced in Buffalo, where he was on the staff of the Buffalo Eye and Ear Infirmary; died Aug. 17, aged 81, of arteriosclerotic heart disease.

Belnap, H. Earl ⊕ Sparks, Nevada; University of Illinois College of Medicine, Chicago, 1924; past-president of the Washoe County Medical Society; member of the American Academy of General Practice; formerly on the state board of health; served during World War I; past-president of the Sparks Lions Club; died in Reno June 29, aged 64, of acute myocardial infarction and hypertension.

⊕ Indicates Member of the American Medical Association.

Buchanan, Edwin Porter ⊕ Pittsburgh; Harvard Medical School, Boston, 1917; professor of surgery at the University of Pittsburgh School of Medicine; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; served overseas during World War I; a director of the Pittsburgh Skin and Cancer Foundation; on the staff of the Mercy Hospital; died in Beverly, Mass., July 11, aged 65, of emphysema and congestive heart disease.

Chowning, William C. ⊕ New Smyrna Beach, Fla.; University of Maryland School of Medicine, Baltimore, 1904; died June 24, aged 72, of congestive heart disease.

Christman, Paul William ⊕ Sacramento, Calif.; Johns Hopkins University School of Medicine, Baltimore, 1916; member of the California Society of Pathologists and the Sacramento Society for Medical Improvement; on the staff of Mercy Hospital; died June 23, aged 65, of coronary occlusion.

Dando, George H. ⊕ Hartford City, Ind.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, Chicago, 1905; died June 28, aged 87, of cancer of the stomach.

DiPasquale, Stephen Gaspar ⊕ Buffalo; University of Buffalo School of Medicine, 1929; interned at the Sisters of Charity Hospital, where he was on the staff and where he died June 1, aged 50, of a fracture of the skull.

Duckworth, Milton ⊕ Carolina, R. I.; College of Physicians and Surgeons, Boston, 1900; served as a member of the House and Senate in the Rhode Island General Assembly; town council president, town health officer, state medical examiner, and superintendent of Charlestown schools; died Aug. 26, aged 80, of coronary thrombosis.

Duncan, Isaac Greenwood ⊕ Memphis, Tenn.; College of Physicians and Surgeons, Memphis, 1909; specialist certified by the American Board of Urology; formerly on the faculty of the University of Tennessee College of Medicine; member of the American Urological Association; fellow of the American College of Surgeons; past-president of the Memphis Urological Society; served on the staffs of the Methodist, St. Joseph's, and Baptist hospitals; died July 24, aged 70, of coronary thrombosis.

Goff, Milton Guy, Utica, Mich.; Detroit Homeopathic College, 1905; died in St. John's Hospital, Detroit, June 28, aged 74, of ruptured aneurysm of the abdominal aorta.

Hall, Philip Vought ⊕ Moline, Ill.; Chicago Medical School, 1936; member of the American Society of Anesthesiologists; served during World War II; died in Nanuet, N. Y., June 16, aged 48, of brain abscess.

Haynes, Halbert Andrew ⊕ Chicago; University of Louisville (Ky.) Medical Department, 1898; interned at the Illinois Charitable Eye and Ear Infirmary; served during World War I; specialist certified by the American Board of Ophthalmology; died in St. Petersburg, Fla., July 5, aged 84, of acute cholelithiasis.

Henderson, Abby May, Niles, Mich.; University of Colorado School of Medicine, Denver, 1912; on the staff of Powating Hospital; died July 26, aged 75, of carcinoma of the uterus.

Jones, Charles Bonham, Knoxville, Tenn.; Kentucky School of Medicine, Louisville, 1898; for many years president of the board of Fort Sanders Hospital; at one time on the faculty of Lincoln Memorial University Medical Department; died in the Fort Sanders Presbyterian Hospital Aug. 11, aged 88, of cancer of the prostate and pneumonia.

Kauffman, William Allen ⊕ Marshalltown, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1898; on the staffs of St. Thomas Mercy Hospital and the Evangelical Hospital, where he died July 29, aged 81, of arteriosclerotic heart disease.

Keneipp, Edgar Percy, Sterling, Va.; George Washington University School of Medicine, Washington, D. C., 1909; died July 7, aged 90.

Keyser, Carl Shurz ⊕ Washington, D. C.; Columbian University Medical Department, Washington, 1898; formerly on the staff of the Garfield Memorial Hospital; died July 22, aged 83, of arteriosclerotic heart disease.

Landham, Jackson Wiley ⊕ Atlanta, Ga.; Atlanta School of Medicine, 1911; specialist certified by the American Board of Radiology; member of the Radiological Society of North America, Georgia Radiological Society, and the American College of Radiology; chief roentgenologist, St. Joseph's Infirmary, visiting roentgenologist at the Piedmont Hospital, Grady Memorial Hospital, Georgia Baptist Hospital, and the Crawford W. Long Memorial Hospital, where he died July 1, aged 71, of ruptured duodenal ulcer.

Lester, Harry Sumner ⊕ Streator, Ill.; State University of Iowa College of Medicine, Iowa City, 1898; member of the American Academy of Ophthalmology and Otolaryngology; formerly mayor of Streator; veteran of World War I; for two terms county coroner; for years served on the public school board; on the staff of St. Mary's Hospital; died in Veterans Administration Hospital, Dwight, June 24, aged 84, of cerebral vascular accident and arteriosclerotic heart disease.

Lightstone, Abraham ⊕ New York City; University and Bellevue Hospital Medical College, New York City, 1902; fellow of the American College of Surgeons; taught at New York University and Fordham University; served on the staffs of the Sydenham and Jewish Memorial hospitals; died in Atlantic Beach, L. I., Aug. 6, aged 80, of coronary disease.

Little, George Reed, Wichita, Kan.; Northwestern University Medical School, Chicago, 1907; served on the board of the Wesley Hospital; died near Lamar, Colo., July 13, aged 75, of myocardial infarction.

Londrigan, Joseph Francis II ⊕ Hoboken, N. J.; St. Louis University School of Medicine, 1937; fellow of the American College of Surgeons; served overseas during World War II; member of the Hudson County Mosquito Commission; physician and surgeon for the city fire department; on the staff of the Jersey City Medical Center; interned at St. Mary's Hospital, where he was a member of the staff and where he died Aug. 1, aged 46.

Longenecker, Charles Willard ⊕ Kingman, Kan.; Kansas City (Mo.) Medical College, 1899; veteran of World War I; served as county health officer and coroner; died Aug. 6, aged 83, of arteriosclerosis.

McCarver, William C. ⊕ Vidette, Ga.; Memphis (Tenn.) Hospital Medical College, 1910; on the staff of the Burke County Hospital in Waynesboro; died in the University Hospital, Augusta, July 24, aged 72, of cerebral hemorrhage.

McGrail, Matthew Augustine ⊕ Bradford, Pa.; University of Pittsburgh School of Medicine, 1931; interned at the Allegheny General Hospital in Pittsburgh and the Clearfield (Pa.) Hospital; served in the U. S. Naval Reserve during World War II; on the staff of the Bradford Hospital; died in the Warren (Pa.) General Hospital June 21, aged 52, of acute myocardial infarction.

McIntyre, Douglas, St. John, Wash.; Georgetown University School of Medicine, Washington, D. C., 1901; past-president of the Whitman County Medical Society; formerly mayor and member of the school board; served during World War I; died July 25, aged 79, of chronic pyelonephritis.

Maloney, Arnold Hamilton, Charlotte Amalie, V. I.; Indiana University School of Medicine, Indianapolis, 1929; on the staff of the Knud Hansen Memorial Hospital; formerly on the faculty of Howard University School of Medicine in Washington, D. C.; died in Freedmen's Hospital, Washington, D. C., Aug. 5, aged 67, of myocardial infarction.

Manson, Richard Hawes ⊕ McKenney, Va.; University College of Medicine, Richmond, 1905; died in Petersburg July 3, aged 72, of cerebral hemorrhage.

Mason, David Adams ⊕ Selma, Ala.; Maryland Medical College, Baltimore, 1904; on the staffs of the Good Samaritan Hospital and Selma Baptist Hospital, where he died Aug. 8, aged 73.

Meacham, Hubert Franklin ⊕ El Paso, Texas; University of Illinois College of Medicine, Chicago, 1916; formerly practiced in Chicago, where he was on the staffs of the Bethany and Garfield Park Community hospitals; member of the Illinois State Medical Society; died in La Jolla, Calif., July 29, aged 64, of arteriosclerosis and myocardial infarction.

Meagher, John Ignatius ⊕ Colonel, U. S. Army, retired, College Park, Md.; Fordham University School of Medicine, New York City, 1913; entered the Medical Corps of the U. S. Army Nov. 30, 1920, and retired Sept. 30, 1949, for disability in line of duty; served during World Wars I and II; assistant director of student health, University of Maryland; died in the Walter Reed Army Hospital, Washington, D. C., Aug. 1, aged 65, of myocardial infarction.

Miller, William John, Estacada, Ore.; University of Oregon Medical School, Portland, 1910; died in Gresham April 30, aged 75, of cancer.

Nassar, Naif Easa ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1909; on the staff of the Illinois Masonic Hospital, where he died Aug. 24, aged 68, of bronchiogenic carcinoma.

Nicholson, John Henry ⊕ Hart, Mich.; Detroit College of Medicine, 1897; for 25 years treasurer of the Oceana Hospital, where he died Aug. 6, aged 86, of duodenal ulcer.

Norrel, John W., Indianapolis; Western Reserve University Medical Department, Cleveland, 1898; died June 17, aged 81, of cardiovascular disease.

Owen, James Alexander ⊕ Detroit; Meharry Medical College, Nashville, Tenn., 1916; served as president of the board of trustees of the Wilberforce University in Cleveland; died in the Wayne Diagnostic Hospital July 6, aged 63, of monocytic leukemia.

Pattison, Jean Harwood, New York City; Cornell University Medical College, New York City, 1919; member of the Medical Society of the State of New York; for many years associated with the St. Luke's Hospital; formerly on the staff of Bellevue Hospital; died in Falmouth, Mass., May 31, aged 68, of carcinoma of the pancreas.

Pavlides, Theodosios Demetrios Khadzi-Tolosogleu, Fresno, Calif.; National University of Athens School of Medicine, Greece, 1911; for many years practiced in San Francisco, where he was chief of staff at the Franklin Hospital; died Aug. 23, aged 65.

Perry, Benjamin, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; retired city and federal food inspector; died Aug. 6, aged 78, of coronary occlusion.

Peters, Edgar, Miami, Fla.; Atlanta School of Medicine, 1911; member of the Florida Medical Association; in 1915 president of the Dade County Medical Association; from 1912 to 1915 first health officer for the City of Miami; on the staff of the Jackson Memorial Hospital from 1922 to 1952; died July 16, aged 69, of bronchopneumonia and arteriosclerosis.

Ruddick, Hobart Conway ⊕ Evansville, Ind.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1912; past-president of the Vanderburgh County Medical Society; past-president of the Indiana State Board of Medical Registration and Examination; formerly member of the city board of education; on the staffs of the Protestant Deaconess Hospital, Welborn Memorial Baptist Hospital, and St. Mary's Hospital, where he died July 28, aged 69, of amyotrophic lateral sclerosis.

Russell, Eldon Leo ⊕ Cleveland; Western Reserve University School of Medicine, Cleveland, 1921; interned at the Cleveland City Hospital; for many years physician on the medical staff of the city board of education; member of the Cleveland Academy of Medicine; on the staff of the Evangelical Deaconess Hospital, where he died Aug. 22, aged 62, of leukemia.

Schlesman, Charles Harry ⊕ Allentown, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; an associate member of the American Medical Association; on the staff of the Allentown Hospital and the Sacred Heart Hospital, where he died July 19, aged 84, of ruptured duodenal ulcer.

Schmit, Felix ⊕ Milwaukee; Milwaukee Medical College, 1900; on the staffs of St. Michael, St. Joseph's, and St. Anthony's hospitals; died July 24, aged 82, of chronic myocardial degeneration and arteriosclerosis.

Schneider, Elias ⊕ New York City; University of St. Andrews Conjoint Medical School, St. Andrews and Dundee, Scotland, 1934; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychosomatic Society; served during World War II; formerly a resident in the New York State Psychiatric Institute and Hospital; died in the Mount Sinai Hospital June 20, aged 47, of a heart attack.

Siefert, Carl Fred, Milwaukee; Rush Medical College, Chicago, 1903; served on the staffs of the Deaconess and Mount Sinai hospitals; died in the Milwaukee County Hospital, Wauwatosa, Wis., July 19, aged 76, of bronchopneumonia, cerebral thrombosis with infarction, and arteriosclerosis.

Terrell, Earley Thomas Jr. ⊕ Richmond, Va.; Medical College of Virginia, Richmond, 1929; specialist certified by the American Board of Psychiatry and Neurology; member of the Richmond Academy of Medicine and the American Psychiatric Association; served in the U. S. Naval Reserve during World War II; at one time on the staff of the Eastern State Hospital in Williamsburg; on the staff of the Veterans Administration Hospital, where he died July 17, aged 48, of carcinoma of the stomach.

Thornton, Ross Cook Blakeney, Vale, Ore.; University of Oregon Medical School, Portland, 1931; interned at the Multnomah Hospital in Portland; on the staff of the Malheur Memorial Hospital in Nyssa; died July 25, aged 53, of coronary thrombosis.

Tomlinson, Carlton Hagg ⊕ Indianapolis; Medical College of Indiana, Indianapolis, 1895; for many years county health commissioner; on the staff of the Riverview Hospital in Noblesville, where he died June 20, aged 86, of cardiorenal disease.

Trimble, William Hugh ⊕ Atlanta, Ga.; University of Pennsylvania School of Medicine, Philadelphia, 1927; fellow of the American College of Physicians; specialist certified by the American Board of Internal Medicine; served during World War II; on the faculty of the Emory University School of Medicine; on the staffs of the Emory University, Georgia Baptist and Piedmont hospitals; died July 26, aged 52, of adenocarcinoma of the lung.

Varner, Winter Thomas ⊕ Flushing, Ohio; University of Pittsburgh School of Medicine, 1938; served during World War II; died July 1, aged 42, of a heart attack.

Walsh, Edward Francis ⊕ Castle Point, N. Y.; Fordham University School of Medicine, New York City, 1911; formerly practiced in New York City, where he was on the staffs of the New York Foundling Hospital, Misericordia Hospital, and St. Vincent's Hospital, where he interned; served on the staff of the Mary Immaculate Hospital in Jamaica; chief physician at the Veterans Administration Hospital; died in Beacon June 26, aged 70, of pneumonia.

Williams, Harry George ⊕ Burlington, Vt.; University of Vermont College of Medicine, Burlington, 1906; member of the New Hampshire Medical Society; formerly practiced in Keene, N. H., where he was on the staff of the Elliot Community Hospital; died July 30, aged 71, of cancer of the pancreas and liver.

Wilson, Edmund Winfred ⊕ Larchmont, N. Y.; Tufts College Medical School, Boston, 1907; an associate member of the American Medical Association; for many years assistant superintendent of the Boston City Hospital; formerly affiliated with the medical department of the Metropolitan Life Insurance Company; died in the New Rochelle (N. Y.) Hospital Aug. 14, aged 70, of cirrhosis of the liver.

Wolff, Maurice Wolkowitz, New Rochelle, N. Y.; Albany (N. Y.) Medical College, 1904; resident at the Passaic County Welfare Home (Hope Dell) in Paterson, N. J., where he died Aug. 6, aged 74, of coronary occlusion.

Wonka, Warren Joseph, Sarasota, Fla.; Harvard Medical School, Boston, 1949; served an internship and residency at the Charity Hospital of Louisiana in New Orleans; an officer in the Medical Corps of the U. S. Army Reserve from July 1, 1953, to June 30, 1955, when he was retired for disability; certified by the National Board of Medical Examiners; died in North Hills, N. Y., July 19, aged 31, of carcinoma of the lung and liver.

FOREIGN LETTERS

AUSTRIA

Solitary Pelvic Kidney.—At the meeting of the Austrian Society of Urology on April 27, Dr. Pfeiffer reported on a 35-year-old man who had a solitary kidney on the left side. The patient was hospitalized because of colic-like pains, but his symptoms subsided within a few days. He was subjected to intravenous pyelography, retrograde pyelography, pneumoradiography, and aortography, but none of these examinations revealed a second kidney. He also had spina bifida, testicular atrophy on the left side, and azoospermia. There was no renal decompensation.

Unusual Form of Perinephritis.—At the same meeting Dr. Übelhör told of a 32-year-old patient with severe pains in the right lumbar region of several months' duration that could be suppressed only by narcotics. The pyelograms did not permit a definite diagnosis. Surgical exposure of the kidney showed the entire anterior surface of the kidney to be covered with a sugar-icing-like covering that fluctuated. Puncture revealed a clear ropy fluid, which could be drawn out into a thread. The entire formation could be stripped off of the kidney without much bleeding, because it had a thick, fibrous wall. The patient was free from symptoms during the months following this operation, and there were no changes in the pyelographic pictures.

Effect of Estrogens on the Testes.—At the same meeting Dr. Zehetgruber discussed the step-like progression of the effects of estrogen treatment on the basis of histological sections of testes obtained from patients with carcinoma of the prostate. During the early part of the treatment, interstitial edema develops, which leads to nutritional changes within the tubules. During the next stage immature seminiferous cells slough off into the lumen of the tubules, and the basal membrane becomes increasingly thick. In the terminal stage, after prolonged treatment, fibrosis of the testis, accompanied by hyalinization of the basal membrane, results. The interstitial cells generally remain unchanged. In patients in whom the prostatic carcinoma remained untreated, testicular sections were studied before and after intravenous treatment with phosphorylated diethylstilbestrol. The sections revealed the pronounced effect exerted by this preparation within a short time. The effects produced by cortisone consisted chiefly in changes and disturbances in mitosis; otherwise the changes were similar to those induced by estrogens. The testicular biopsies were obtained by stab incisions into the tunica albuginea. A piece the size of a pea was removed from the parenchymatous material oozing through the stab wound, and the opening was closed. The sections were obtained mostly from material that became available as the result of therapeutic orchiectomies.

Repeated Cesarean Section.—To determine whether repeated cesarean sections are technically more difficult and more dangerous to the patient than the first operation, Araujo and Neme studied the records of 951 patients on whom cesarean sections were performed. Of these patients, 133, or 14%, had had repeated cesarean sections (*An. brasil. ginec.* **20**:253, 1955). In 120 of the 133 patients the operation had been performed twice, and in 13, three times. Pelvic contraction was the indication for operation in 89, cervical dystocia in 17, placenta previa in 6, cephalopelvic disproportion in 4, functional dystocia and difficult presentation in 3, previous tumor and incomplete uterine rupture in 2, and fetal anoxia associated with placenta previa in one. Uterine rupture occurred in only three patients, and the integrity of the uterus was preserved in five patients in spite of the presence of Bandl's ring. In the repeated cesarean sections, spinal anesthesia was used in 71%, while in the first section it was used in 66%. Low transverse section was used in 95.4%, and in 4.6% corporal section was performed because of technical difficulties created by adhesions. While the maternal fatality rate was 3.6% in the first cesarean sections, in repeated sections it was only 0.75%. The fetal mortality rate was 9.4% for the first cesarean sections and 3.7% for the repeated sections. These improved results of repeated sections are attributed by the authors to better care of the patients and the anticipation of difficulties connected with the repetition of the procedure.

High Caloric Value in Parenteral Feeding.—After major operations performed on the esophagus and the stomach and after multiple visceral resections, it is necessary to see that the patient gets enough water, electrolytes, proteins, and calories. Owing to the difficulty of introducing fat directly into the veins to furnish an adequate supply of calories, surgeons are more and more resorting to alcohol as an abundant source of energy. Dr. Fernando Paulino in *Revista brasileira de cirurgia* (**29**:339, 1955) reported a study of this procedure in 200 patients on whom he performed major operations. These patients received intravenously a total of 1,600 liters of solutions containing 10% dextrose, 5% amino acids, 9% alcohol, and electrolytes and vitamins. No serious accidents were observed. The solution yields about 1,000 calories per liter, thus giving the patients an adequate caloric intake without danger of superhydration. A group of 30 patients was studied in regard to water; total nitrogen, sodium, and potassium balance; glycosuria if any; and the nonprotein nitrogen level in the blood. The study revealed that (1) positive nitrogen balance could be maintained by parenteral therapy alone; (2) the intravenous use of alcohol did not interfere with the water, sodium, and potassium balance or the nonprotein nitrogen level; and (3) glycosuria seldom occurred and could be corrected by reducing the speed of the infusion.

ENGLAND

Mental Hospital Reports.—The annual report of the Crichton Royal Hospital, Dumfries, states that electroconvulsive therapy is the treatment of choice in manic-depressive disorders and involutional melancholia and insulin coma therapy is recommended for schizophrenia. Thiopental and succinylcholine are being used increasingly with electroconvulsive therapy. Disulfiram continues to be used in selected patients with alcoholism, but always in conjunction with psychotherapy and such other treatment as insulin and large doses of vitamins, which have been found useful in chronic alcoholism. Modified insulin therapy, carbon dioxide therapy, abreactive therapy, acetylcholine injections, and prolonged narcosis continued to be used in selected patients with neuroses and mild psychoses. During the year 19 standard leukotomies were performed. Fully one-third of those who had this operation have been discharged as socially recovered, and, of these, the majority are gainfully employed. Another third are much improved though still requiring hospitalization. The best results continue to be obtained in those whose preoperative personalities were largely intact and who had well-adapted personalities before their breakdown. In appraising these results it is necessary to bear in mind that with few exceptions the patients operated on were schizophrenics who failed to respond to other methods of treatment and who were otherwise destined to spend the remainder of their lives as severe mental invalids. To date, 491 leukotomies have been performed on 450 patients.

In the department of clinical research, work was continued on the biochemical aspects of the mechanism of action of *d*-lysergic acid diethylamide. In vitro studies of the effect of the drug did not confirm earlier findings that small concentrations of it stimulated cerebral respiration. At high concentrations of *d*-lysergic acid diethylamide, however, the respiration of

AUSTRIA

Solitary Pelvic Kidney.—At the meeting of the Austrian Society of Urology on April 27, Dr. Pfeiffer reported on a 35-year-old man who had a solitary kidney on the left side. The patient was hospitalized because of colic-like pains, but his symptoms subsided within a few days. He was subjected to intravenous pyelography, retrograde pyelography, pneumoradiography, and aortography, but none of these examinations revealed a second kidney. He also had spina bifida, testicular atrophy on the left side, and azoospermia. There was no renal decompensation.

Unusual Form of Perinephritis.—At the same meeting Dr. Übelhör told of a 32-year-old patient with severe pains in the right lumbar region of several months' duration that could be suppressed only by narcotics. The pyelograms did not permit a definite diagnosis. Surgical exposure of the kidney showed the entire anterior surface of the kidney to be covered with a sugar-icing-like covering that fluctuated. Puncture revealed a clear ropy fluid, which could be drawn out into a thread. The entire formation could be stripped off of the kidney without much bleeding, because it had a thick, fibrous wall. The patient was free from symptoms during the months following this operation, and there were no changes in the pyelographic pictures.

Effect of Estrogens on the Testes.—At the same meeting Dr. Zehetgruber discussed the step-like progression of the effects of estrogen treatment on the basis of histological sections of testes obtained from patients with carcinoma of the prostate. During the early part of the treatment, interstitial edema develops, which leads to nutritional changes within the tubules. During the next stage immature seminiferous cells slough off into the lumen of the tubules, and the basal membrane becomes increasingly thick. In the terminal stage, after prolonged treatment, fibrosis of the testis, accompanied by hyalinization of the basal membrane, results. The interstitial cells generally remain unchanged. In patients in whom the prostatic carcinoma remained untreated, testicular sections were studied before and after intravenous treatment with phosphorylated diethylstilbestrol. The sections revealed the pronounced effect exerted by this preparation within a short time. The effects produced by cortisone consisted chiefly in changes and disturbances in mitosis; otherwise the changes were similar to those induced by estrogens. The testicular biopsies were obtained by stab incisions into the tunica albuginea. A piece the size of a pea was removed from the parenchymatous material oozing through the stab wound, and the opening was closed. The sections were obtained mostly from material that became available as the result of therapeutic orchiectomies.

cerebral homogenates and slices was inhibited 15 and 25% respectively. This inhibition was also obtained with the related monoethylamide and when the substrate was pyruvate instead of glucose. In liver preparations a much smaller inhibition of respiration occurred at the high concentration of *d*-lysergic acid diethylamide. In view of the suggestion that a previous injection of nicotinic acid prevented the symptoms of *d*-lysergic acid diethylamide intoxication, thus indicating that the drug might act by inhibiting the pyridine-nucleotide-dependent enzymes, the effect of diphosphopyridine nucleotide on the inhibition by *d*-lysergic acid diethylamide of cerebral respiration was investigated, but with negative results. The observation that the drug affected the metabolism of hexosemonophosphate was reinvestigated, using revised techniques. The hexosemonophosphate changes in vivo were shown to be possibly due to a response in the formed elements of the blood to *d*-lysergic acid diethylamide. Attention has also been directed to 5-hydroxytryptamine, which is reported as having a wide natural distribution in the central nervous system; one of its observed actions (that on smooth muscle) is inhibited by *d*-lysergic acid diethylamide and other structurally related "hallucinogens."

At the Retreat, York, insulin coma is the treatment of choice for schizophrenia as in the Crichton Royal Hospital. During the year this treatment was given to 46 patients, of whom 25 received substantial benefit. Electroshock was the main form of treatment in psychotic depression of the so-called endogenous type. About 66% of this treatment is now given with thiopental and succinylcholine in specially equipped centers. Given by experienced hands the treatment is safe, but the highest standard of safety is best maintained by carrying it out in a properly equipped center where everything is immediately available for even the most unlikely contingency. The treatment may be given to outpatients only if exceptional circumstances make it essential. Complications are fortunately rare, but if they do occur it is better that they occur in the hospital where immediate help is available. During the year 12 or more patients who had begun treatment elsewhere as outpatients were admitted to the hospital. Electroshock ideally should be given to patients in the hospital, at least the first two or three applications, so that reactions can be observed and the patients reassured. Apomorphine has been given to a number of alcoholic patients with some success, though on the whole it has proved disappointing. Chlorpromazine and reserpine have been used to treat states of tension, anxiety, and depression, but so far the results indicate that their use is likely to be limited because, although they produce the kind of effect sought, the effects frequently are not of sufficient strength. *d*-Lysergic acid diethylamide may make a few patients previously immune to psychotherapy more suitable for it, but in some patients it may shorten the course.

An Experimental Health Center.—In April, 1954, a new health center was established in Manchester by the university and sponsored by the Nuffield and the Rockefeller foundations (*J. A. M. A.* **155**:1443 [Aug. 14] 1954). The general practitioner section of the center, which is the only one functioning so far, consists of a central office; four suites, each consisting of a waiting room, examining room, and consulting room; a treatment room; an x-ray room; and a laboratory. The center is administered by a board consisting of the four general practitioners whose offices are in the center, representatives of the university, the city council, the executive committee, and the local medical committee. The combined lists of the four physicians include 13,000 patients. The average attendance at the center has been 3,160 a month. As a result of the experience gained at the center laboratory it was recommended that (1) facilities be provided on the spot for hemoglobin determinations, leukocyte counts, and smears; (2) facilities be provided in every center for practitioners and patients to take their specimens at their convenience for transmission to a central laboratory for more complex tests; (3) results of tests be reported as soon as possible (telephone information is a great help); and (4) if possible a technician should go out with the doctor in his car to take smears or make blood cell counts in the patient's home.

Among the salient points brought out by the laboratory results obtained in this center is the unexpectedly high incidence of anemia that was detected; 50% of the 801 estimations of hemoglobin showed levels of less than 85%, and levels of less than 60% were common. Of 114 throat swabs, only 35 showed any pathological organisms; of these, 4 were penicillin-resistant. The report comments that "it may be questioned whether, even with facilities available, it is worth while doing routine swabs on infected throats." On the other hand, all 60 of the cultures taken from boils and carbuncles grew pathological organisms, of which 20 were penicillin-resistant. The inference drawn from this is that thousands of patients must be receiving penicillin injections for boils that are penicillin-resistant. Of 83 cultures of catheterized urine, 23 were positive and of these, 4 were penicillin-resistant and 4 were sulfonamide-resistant. As these are the two most commonly used drugs in urinary infections, it is suggested that the repeated lapses encountered in practice may be due to failure to determine the drug sensitivity of the organism and the consequent failure to use correct treatment.

This is the only general practitioner health center that has its own x-ray facilities. The work of the x-ray unit is supervised by a radiologist from the local teaching hospital. During the year 1,479 x-ray examinations were made on 1,267 patients, of whom 333 were found to have abnormal findings. Some criticism has been made on the grounds of cost, but the help given to patients and the high percentage of abnormal findings would seem to justify the expense of running this department. Nursing was provided by three nurses from the Manchester District Nursing Institute. By arrangement with the city, they combined the home nursing for the center with the nursing in the center. It is difficult, however, to get nurses for this type of work because of the irregular hours and exposure to inclement weather. On the whole the experiment has succeeded. The team spirit has developed satisfactorily, and the patients have attended in great strength. One of the most important discoveries has been that with all the ancillary help of secretaries and nurses, the work does not diminish and the physicians do not enjoy an easier time.

Epidemic in London Hospital.—Doubt now exists as to whether the epidemic that closed the Royal Free Hospital and that was reported in this section was infectious mononucleosis as was originally suggested. The epidemic has now involved 83 nurses, 5 physicians, 11 of the ancillary staff, 8 students, and 22 of the domestic staff. Doubt is being thrown on the original diagnosis in view of many unusual features that have been observed. The lymph nodes, liver, and spleen are involved, and most of the patients show signs and symptoms of encephalomyelitis or polyneuritis. The disease has usually run a benign course. The incubation period appears to be five to seven days. Most of the victims have been young nurses, but several of those over 40 have been affected. The initial symptom has been vague malaise, followed within one to seven days by mild sore throat; tender enlargement of the lymph nodes, often confined to the posterior cervical region but in some cases generalized; and pain of varying severity under both costal margins and in the neck, back, and limbs. Headache without meningism has been common, but the symptom that seems to be peculiar to this infection, especially in the early stages, is vertigo. Symptoms and signs of encephalomyelitis have appeared in some patients within 48 hours of the onset, but in others the neurological complications have been delayed for as long as three weeks. Cranial nerve palsies, particularly ocular, have been common, and mild paresis of either the pyramidal or lower motor neuron type has been observed, sometimes with painful muscle spasms. Paresthesia, numbness, neuralgic pains, or anesthesia, have appeared either alone or in association with motor manifestations. Coma has not been observed, but a state of drowsiness has been relatively common.

Tenderness of the lymph nodes has been accompanied in some patients by extreme tenderness in the region of the liver and over the spleen. Liver enlargement has been definite, but tenderness has made it difficult to determine the size of the spleen. Even when the infection has been severe, fever has been slight or absent. In certain patients there has been a disproportionate tachycardia, sometimes persisting into convalescence. Total leukocyte counts have varied from 3,000 to 12,000 per cubic millimeter, sometimes with neutropenia and occasionally with an absolute lymphocytosis. Mononuclear cells have not been observed, but morphological changes have occurred in some lymphocytes. The Paul-Bunnell test has not been positive in a single patient. The spinal fluid has been examined in a few patients, but in none was there a pleocytosis or an increase in the protein content.

In an official account issued by the Royal Free Hospital, it is stated that it seems doubtful that this is an outbreak of infectious mononucleosis, for, though the neurological complications encountered have been described in reports of the disease, they were exceptional in other epidemics whereas in the present epidemic they are almost the rule. Furthermore, laboratory tests have failed to support the original diagnosis. On the other hand, in the epidemic variant of infectious mononucleosis hematological and serologic changes typical of this disease are not constant. The high infectivity, the prominence of visceral manifestations, the frequency of sensory neurological signs combined with the predominantly benign course make a diagnosis of poliomyelitis most unlikely. The studies in progress may establish that the infection is due to a known virus or its variants, but it is possible that a new virus is involved.

Caring for the Elderly in Scotland.—In an address to the annual general meeting of the Edinburgh Council of Social Service, Mr. H. R. Smith, Secretary of the Department of Health for Scotland, outlined some of the work that was being done in Scotland for the care of the elderly under the National Health Service. The home nursing service, which all local health authorities are required to provide free of charge, was responsible for 2,915,000 visits in 1954, covering 161,000 patients. About a third of these patients were older people. Under the National Health Service local health authorities can provide domestic help for elderly people, not in need of nursing but requiring more care and attention than they can provide for themselves. At the end of 1954, local authorities employed 780 full-time and 3,200 part-time domestic workers who were called to 18,600 households, and in nearly half of these older people were living. One local authority has provided a clinic to which elderly people, after consultation where desirable with their physician (or sometimes at his suggestion), can go for a special medical examination. Valuable work is also being done by voluntary agencies. There are, for instance, about 200 welfare committees for older people in Scotland that arrange for outings, concerts, home visits, and clubs for the elderly. These organizations have also initiated and expanded meal services for older people, and there are now 47 such services in Scotland. Of the 85 chiropody services now in operation, 74 are provided by voluntary agencies. For older people who can no longer stay in their homes, there are 1,800 places in small modern homes, with another 600 in prospect in homes that are being built or planned, as compared with about 4,500 remaining in the older and larger establishments. These are all provided by local authorities. In addition, just over 4,000 persons are accommodated in voluntary homes for older people.

One of the recent major developments has been the opening of a geriatric unit of 70 beds at Stobhill Hospital, Glasgow. In its first nine months 484 patients were admitted and 124 were discharged home. In the geriatric unit at Maryfield, Dundee, which has now been in operation for several years, results indicate that about 45% of the patients admitted can be restored to a condition in which they can live outside the hospital, either in their own homes or in a hostel. Since the family physician is busy, he often learns of a particular patient only when it is too late for preventive work. He should, however, be not only an agent for treating disease but also the man to whom a patient or a patient's relatives can turn for help and advice in obtaining any of the health, welfare, or voluntary services that can be provided. Coordination is necessary so that everybody who plays any part in the health and welfare services may know what facilities are available in any other part of the field. Although 25 local coordinating committees have been set up in Scotland, made up of representatives of the hospital service, local authorities, and executive councils, it might be better to form small *ad hoc* committees to meet specific problems as they arise. From such committees general practitioners could tell where need existed and learn what help was available.

Accidents in Schools.—A survey of accidents occurring in the schools of Buckinghamshire during a two year period has been made by J. J. A. Reid (*Medical Officer* 94:107, 1955). In a school population of 25,939 boys and 24,065 girls, aged 5 to 15 years, there were during this period 954 accidents, involving 618 boys and 336 girls. This gives an annual accident rate of 1.2% for boys and 0.7% for girls. The rates for both boys and girls showed a general upward trend from the age of entering to that of leaving school. Throughout the entire period, at all ages, the accident rates for boys were substantially higher than those for girls. About 40% of the accidents occurred in the playground. Accidents during sports and physical education classes accounted for 25% of all accidents to boys and 33% of all accidents to girls; accidents in classrooms accounted for 20.5% of accidents to boys and 15.8% of those to girls; and accidents in corridors, cloakrooms, bathrooms, and on stairs accounted for 5.7% of accidents to boys and 8.6% of those to girls. Superficial abrasions and contusions were incurred by 41% of the boys and 40.2% of the girls; lacerations were incurred by 22.6% of the boys and 11% of the girls; fractures, mostly of the arms and legs, were incurred by 18.1% of the boys and 19.9% of the girls; muscle, tendon, and joint injuries were incurred by 9.4% of the boys and 17.3% of the girls; foreign bodies were responsible for 2.6% of the accidents to boys and 3% of those to girls; minor concussions occurred in 1.6% of the boys and 0.9% of the girls; and the rest included dental accidents and burns and scalds. There was only one fatal accident; a boy of 14 sustained an apparently trivial accident in the gymnasium, for which he appeared to be none the worse. He died during the night. The primary cause of death was repeated subdural hemorrhages associated with an old cyst of the arachnoid membrane and an abnormally thin skull. The only other serious injury was a ruptured liver sustained by a boy who fell while sliding down bannisters. Information concerning contributory factors was available in 171 accidents: disobedience to rules (6.8% of accidents in boys and 3.6% of those in girls); rough play or behavior (5.2% of accidents in boys and 2.1% of those in girls); structural defects (3.7% of accidents in boys and 3.6% of those in girls); accidents involving doors (2.4% of accidents in boys and 4.2% of those in girls); and accidents secondary to illness (1.1% of accidents in boys and 2.1% of those in girls). Of the last group, two were caused by falls during epileptic seizures and several were due to fainting. In noting that 22 of these accidents occurred in school gardens, the question is raised as to whether it would not be a wise policy to immunize all school children routinely with tetanus toxoid, because children from 5 to 14 years of age have the highest civilian death rate from tetanus. The most practical way of dealing with this situation might be the administration of a combined diphtheria-pertussis-tetanus injection at child welfare clinics, with subsequent booster doses at school.

Employment of the Cardiac Patient.—The British Council for Rehabilitation has issued a report on the employment of patients with heart disease. In children unwarranted invalidism was found to be common. Half of the children in whom abnormal cardiac signs were reported in school medical examinations were shown to be healthy in a subsequent special examination. It is therefore recommended that each child in whom an abnormal cardiac physical sign is found be reexamined by a physician specially trained in cardiology. Whenever the child is found to be healthy and the presenting sign to be innocent, such information should be conveyed emphatically to the parents, the school medical officer, and the child's family physician. As soon as heart disease is diagnosed, steps must be taken to prevent the patient from growing into a social derelict. It is important that he should not become introspective and resentful but that he should be helped to find an outlet for his energy; his creative powers should be stimulated in a way that is within his physical range of activity so as not to isolate him from others of his own age. Strong exception is taken to the view that the ambulant child with heart disease is suitable for transfer to a special school or hospital, where physically defective children are cared for. Most children with valvular heart disease should attend ordinary schools. Banks, insurance offices, and the post office have been reluctant to employ persons with heart disease, whose disabilities demand a sedentary occupation, because of the danger of their imposing an undue burden on the insurance and retirement schemes. The committee urges that the Ministry of Labor in conjunction with the Ministry of Health propound a scheme that will provide pension facilities for this deserving group in order to prevent their entry, as is now the rule, into occupations entailing heavy manual labor, where a preliminary medical examination is not required. In the case of heart disease in the elderly, the cardiologist's main function is to make an accurate diagnosis in order to avoid unwarranted invalidism, especially in those patients in whom pain in the chest is shown to arise outside the heart, in those with an elevated blood pressure in whom special tests exclude true hypertension, in those with a displaced apex in whom there is no cardiac enlargement, and in those with murmurs that are immaterial, if not innocent.

Mass Radiography.—In the past mass miniature radiography has been used in surveys of students, factory and office workers, or volunteers, in the hope of discovering tuberculosis and other chest lesions. This is now considered wasteful, and the Medical Research Council has suggested that mass miniature radiography would be used more economically and effectively by limiting it to patients referred by general practitioners and surveys of areas where tuberculosis is unduly prevalent. For the last two years the Northern Ireland Tuberculosis Authority has encouraged general practitioners to refer persons over 14 years of age to the mass miniature radiography center in Belfast without previous appointment. Barr and Ritchie have surveyed results of the scheme (*Tubercle* 36:228, 1955). After the reading of the miniature films a letter is sent within 48 hours to the practitioners concerned stating whether the radiograph is satisfactory or recommending further examination. Patients with active tuberculosis are referred immediately to the local chest clinic and those whose disease is inactive to a general practitioner. Other patients are referred to the appropriate specialist (e. g., a thoracic surgeon). Since the inception of the scheme, 15,917 persons have been radiographed. Over half the examinees were in the age group of 15 to 34 years; few were over 60 or under 15 years. The area covered included 500,000 persons, and about 15 in every 1,000 were x-rayed annually. In the past two years 347 patients were diagnosed as having active postprimary tuberculosis—all but 5 for the first time. This represents 2.2% of the total referred for examination and is much higher than the percentage for other groups surveyed by mass miniature radiography. In organized groups in the area this was 0.34% and in individual volunteers 0.71%. The percentage of nontuberculous chest lesions found in the patients referred by general practitioners, namely 18%, was greater than in either of the organized groups (6.5%) or in individual volunteers (11.2%). The lesions included chronic bronchitis, pneumonitis, bronchiectasis, neoplasms, and cardiovascular lesions. Although the numbers discovered were relatively small (0.45% of the men and 0.2% of the women), it was thought that mass radiography could play an important role in the diagnosis of lung carcinoma. The scheme has stimulated the general practitioner to become more interested in case finding. The scheme saves a patient from being sent to a chest clinic unless a lung lesion has been diagnosed, and it speeds diagnosis.

Fomenting of Lawsuits.—According to the annual report of the Medical Defense Union, the working of the Legal Aid Scheme continues to foment lawsuits and to encourage allegations, often baseless, against members of the medical and dental professions. These would not have been made if their authors had known they might have to pay the court costs. These cases cast heavy burdens on the union's finances. Although the injustices to which the scheme not infrequently leads have been admitted and even deplored by the judiciary, there seems no prospect of any effective redress. For example, a general practitioner was asked to treat an elderly man who had sustained an injury to his back. The physician injected 2% Novutox at the site of the injury and was about to withdraw the needle when it broke off. He was unable to extract the retained fragment and sent the patient to a hospital where, on the following day, the retained part of the needle was removed. In due course the patient sued the physician alleging negligence in the administration of the injection and claiming damages for such items as bus fares to and from hospital, new pajamas and a dressing gown worn in hospital, and loss of wages. The total damage claim was $1,220. When the case came to trial the plaintiff admitted that he had not lost any wages because of the breaking of the needle but because he had refused to accept the alternative post that his employers had offered him on his return to work. He also admitted that his claims for certain other expenses could not be justified and that, far from having been caused pain and suffering, he had rather enjoyed his short stay in the hospital. He offered no medical evidence but called a metallurgist who said the problem was a medical one and not a metallurgical one. In giving judgment for the defendant the judge described the case as an abuse of the Legal Aid Scheme. He found that there had been no negligence on the part of the physician and said that even if the plaintiff had been able to satisfy him on this score the damages to which he would have been entitled amounted to only 50 cents. As the plaintiff was an assisted person of small means, no order for court costs was made.

Culpable Contraceptive Cap.—The annual report of the Medical Defense Union also reports a suit brought against a public health officer who, as part of her duties, attended a birth control clinic. She had fitted a patient with a contraceptive cap and demonstrated and taught its use. Many months afterward the patient, who had been complaining of various symptoms, was x-rayed, and the roentgenogram suggested the presence of a cap covering the cervix. She was referred to the clinic where the cap was removed. It had evidently been in position for a long time. The patient said that, being unaware of its presence, she had for a time been using another. She expressed some exasperation that more recently she and her husband had been hoping to have a baby but had been unsuccessful. An action was brought against the physician based on the allegation that the cap had been left in position after its use had been demonstrated to the patient. This was entirely contrary to the practice of the physician and of the clinic, and a check on the appliances used in the clinic did not reveal any as being missing. The patient thereupon abandoned her suit.

Sanatoriums.—According to Dr. Peter Stradling (*Tubercle* 36:150, 1955) the admission of a patient to a sanatorium has no more beneficial effect on the course of his tuberculosis than has treatment by an adequate clinic where domiciliary, hospital, and outpatient treatment are flexibly integrated according to need. This conclusion is based on a five year follow-up of the 64 patients with newly diagnosed pulmonary tuberculosis who were first seen at his clinic between June, 1948, and June, 1949, a time when there was an acute shortage of sanatorium beds. To compensate for this shortage, these patients were admitted in quick succession to clinic beds in Hammersmith Hospital for initiation of collapse therapy. This was followed by long periods of domiciliary maintenance, and some patients were finally transferred to sanatoriums or rehabilitation centers. The follow-up results showed that quiescence was obtained without active treatment in a sanatorium in 47 of the 64 patients. Sanatorium admission severely breaks the continuity of treatment, and the differences of opinion and changes of treatment likely to be inflicted on the transferred patient only bewilder him, undermine his confidence, and make him skeptical of medical opinion and care. All this is avoided by clinic management where close liaison between patient, physician, hospital, clinic, and the sufferer's family encourage a sound evaluation of needs based on knowledge of all the available factors. Another disadvantage of sanatoriums is the fact that they are usually located in the country many miles from the patient's home, which makes visiting difficult and which leads to a sense of isolation. Furthermore, it aggravates the sense of stigma that many patients suffer.

Shotgun Wounds.—Sir Heneage Ogilvie (*Practitioner* 175:304, 1955) divides shotgun wounds into close-range and long-range injuries. In the former, which usually happen at the end of a day's shooting and are often accidentally self-inflicted, the whole charge, including the wad, enters the tissues as a compact mass. These are lacerated and contaminated wounds that must be treated as soon as possible by excision and drainage. Excision implies the removal of all dead and damaged tissues, all dirt, and all foreign matter down to the depths of the wound. Bones may be broken, but they are seldom comminuted. The fracture ends should be cleansed mechanically, the injured part immobilized, and parenteral administration of chemotherapy instituted. It is unwise to attempt primary suture of any shotgun wound, but early secondary closure is essential in order to minimize scar tissue and secure the best possible function. The usual long-range injury consists of a number of scattered holes. Apart from the eye, where penetration may be deep, the pellets are usually stopped by the fascia. They may lodge in the skin over the abdominal wall and penetrate a short distance into the muscles, but they do not enter the peritoneal cavity. These multiple peppered wounds require no treatment beyond cleaning the skin, applying a sterile protective dressing, and administering chemotherapy.

Prevention of Coronary Disease.—In a public address, Sir Macfarlane Burnett, director of Melbourne's Walter and Eliza Hall Institute for Medical Research, suggested a study of identical twins as a line of approach to coronary disease. Although coronary disease has been associated with worry, diet, and excessive smoking, inherited constitution as an important factor could not be excluded. If one identical twin could be found with heart disease and the other were healthy, it could be assumed that environment was the determining factor. If the causative environmental factors were known, coronary disease might be prevented. It is not yet clear whether the tension of modern life or the smoking that is indulged in to ease that tension is an important factor in the production of coronary disease.

FRANCE

New Angiographic Technique.—Angiography has heretofore been only regional. P. and M. Viallet and their co-workers in Algeria have devised a new system of angiography by means of a single intravenous injection according to their report at a meeting of the Medical Society of Paris Hospitals in March. The patient is first given antihistaminics, barbiturates, and ganglioplegics. An intravenous injection of 3-acetyl-amino-2-4-6-sodium triiodobenzoate is then given, using a vein of the cubital fossa in adults and the external jugular vein in children. In the same syringe, surmounting the contrast medium through a difference in density, physiological saline solution is injected to flush out the veins. The combined injection must be given quickly (1 to 2.5 seconds). The segmental venous hypertension caused by the rapid injection momentarily blocks the local venous circulation, thus helping to prevent the dilution of the contrast medium. The authors have performed 320 angiocardiographies by this method with no significant complications. A generalized thermesthesia is usually observed during the injection. The authors apply the same method to the study of the thoraco-cervico-cephalic region. They thus avoid the use of three successive venipunctures. They have been able by this means to obtain a simultaneous cervical, cranial, and facial study including the collateral circulation. This permits a reasonable surgical plan for operations and a more accurate postoperative prognosis. In the same manner, the authors have studied the thoraco-abdomino-pelvic circulations. They avoid by this method the necessity of giving a general anesthetic and the acute pain associated with intra-arterial injections.

Effects of Hormonotherapy.—At the meeting of the Medical Society of Paris Hospitals on May 6, P. Mozziconacci and his co-workers reported their observations on 57 children between the ages of 18 months and 18 years who were treated with corticotropin and/or cortisone; 43 or 77.3% have had minor accidents and 2 or 3.5% have had serious accidents. Most of these accidents occurred in patients with clinical signs of hypercorticalism. The intensity and the duration of the treatment and the familial as well as personal neuropsychological antecedents are predisposing factors. These antecedents, in view of the seriousness of the disease for which the hormones were given and the relative mildness of the accidents incurred, do not constitute a contraindication to the hormonotherapy. The accidents that are more apt to occur at the beginning and at the end of treatment can be explained by the rapid and extensive variations in metabolism. The occurrence of signs of hypercorticalism and anxiety or insomnia might indicate the need to lower the dose or to discontinue treatments.

Colitis Treated by Hydrocortisone Enemas.—At the meeting of the Medical Society of Paris Hospitals on May 20, P. L. Drouet and his co-workers in Nancy reported the treatment of hemorrhagic rectocolitis with a daily retention enema containing hydrocortisone. The dose was 25 mg. for the first 15 days. After a rest of eight days, 50 mg. per day was given in the same way supplemented by 25 mg. given orally twice a day. Even larger doses may be given rectally. When the symptoms have cleared up the enemas are stopped but the oral doses are continued. The results have been excellent. Proctoscopy showed complete healing of the rectal mucosa. Although the cure has been maintained for several months, it is too soon to tell whether or not the disease will recur.

INDIA

Rauwolfia Serpentina.—At the Medical College of Bombay, Lewis and Gaitonde have studied the activity and toxicity of Rauwolfia serpentina. After the isolation of five active alkaloids from this plant, various fractions have been studied and it has been found that the amount of alkaloid contained in a particular extract depends largely on its source. Biological and chemical methods of standardization have been attempted on the crude extracts, but, because some of the alkaloids have a marked vasodilator action, it is necessary to assess both its central and its peripheral action. The peripheral action is estimated by recording the fall in blood pressure in cats with a transsected spinal cord that also receive a continuous infusion of arterenol (nor-epinephrine). The central sedative activity is estimated from the L.D.$_{50}$ for albino rats. Sedative properties are present in both the total and alcoholic extracts, while the residue after removal of ajmaline and serpentine is higher in sedative properties. The hypertension induced by giving epinephrine and ephedrine is lowered by total alkaloids and by serpentine and to a lesser extent by ajmaline. Clinical trials suggest that the central action is of greater importance than the vasodilator action. The authors draw attention to several important limitations of the methods they have used for the assay of peripheral activity and the measurement of the L.D.$_{50}$ and throw some doubt on the assumption that the latter is correlated with central depressor action. Arterenol was infused at a fixed rate in order to maintain the raised blood pressure, and aqueous extracts of R. serpentina obtained from four different sources were used for comparison. Besides this, four partially purified fractions (serpentine, crude oleoresin, and two ajmaline fractions obtained from different sources) were tested. The central action was studied by intraperitoneal injections of various preparations in albino rats varying in weight from 50 to 100 gm. The L.D.$_{50}$ was calculated for each extract and fraction using two groups of 10 animals each at a dose level above and below L.D.$_{50}$ The authors concluded that reserpine has a far greater toxicity or central depressant action than any of the other fractions but hardly any demonstrable immediate peripheral action. Serpentine has the lowest toxicity and central depressant action but a very high peripheral effect. Ajmaline stands between the two as regards its central and peripheral action.

Melanoma.—Agarwal and Ahuja in the *Indian Journal of Medical Research* (43:2 [April] 1955) reported a case of intraocular melanoma arising from the conjunctiva. The patient, a 35-year-old man, complained of a gradually increasing ulcerating mass in the left eye of six months' duration. This growth had destroyed the left eyeball and had involved the temporal margin of the orbit. The microscopic appearance of the tissue showed wide variations. There was marked proliferation of the epithelium overlying the tumor. Some of the epithelial processes extending into the underlying mass had bulbous ends and looked as if they had left a few cell-rests behind. One block showed a single row of proliferated basal cells, with vacuolated cytoplasm and small pyknotic nuclei penetrating the subjacent stroma, and another block showed a whole column of such cells penetrating downward and disappearing into melanoblasts and melanophores. These basal cells appeared to be the origin of the melanotic growth. The stroma consisted mainly of argyrophilic reticulin fibers with a few collagen bundles interspersed in between and many chronic inflammatory cells, chiefly small round cells and plasma cells. In between these cells a number of pigment-laden histiocytes and other groups of large cells containing melanin were seen. The morphology and arrangement of these cells showed marked variation, being epithelial, transitional, or spindle-shaped. The epithelial cells similarly showed polymorphism. The tumor cells are commonly believed to arise from the basal cells over a segment of scleral conjunctiva, and this is supported by their histological appearance.

Tuberculin Testing.—J. P. Karan, of the Tuberculosis Training Center in Patna, has given a tuberculin test to about 631 children under 6 years of age. The results were read on the fourth day after the test, at which time only 62.9% reported for a reading. About 37.9% of the group reporting had positive reactions. A progressive increase in the percentage of tuberculin positivity was seen with advancing age, the maximum being noticed in the age group 4 to 5. Demonstrable lesions were maximal in the age group 2 to 3. Sex had little effect on the percentage of positive reactions or the development of disease. A positive reaction does not necessarily mean active disease even in infancy and childhood, but, if there are symptoms referable to the chest or of a toxic nature, a thorough investigation of these positive reactors should be made. The size of tuberculin reaction is not helpful in diagnosing tuberculosis.

ISRAEL

Hypothalamic Obesity.—In the course of his studies on endocrinologic disturbances, Hermann Zondek (Bikur Holim Hospital, Jerusalem) found a new type of hypothalamic obesity in adolescents, called by him "Z-type." The underlying mechanism of hypothalamic obesity has been clarified by recent experimental investigations. Bilateral electrolytic lesions in ventromedial nuclei cause overfeeding and adiposity. It appears that the hypothalamic feeding centers can be affected, and their balance disturbed, by chemical, thermal, infectious, toxic, mechanical, and psychic factors. To the group with hypothalamic obesity belong patients with the so-called water-salt obesity, most patients with adiposogenital dystrophy, those with pseudo-Froehlich syndrome (genuine Froehlich types without anatomic substrate), and some patients with adrenal cortical hyperfunction (Cushing's syndrome). Zondek's Z-type represents in its symptoms an intermediate stage between the form of pseudo-Froehlich syndrome and adrenal cortical hyperfunction. It includes the following signs and symptoms: voracious, often uncontrollable, hunger and thirst; Cushing's syndrome-like distribution of the adipose tissue, with moon face, purple cutaneous striae, diffuse purple coloring of the skin, especially over the nates and legs; and signs of vasoconstriction (retinal vessels, limbic capillaries, and tibial arteries). Vertical growth is variable, being in most patients advanced for the age but in others normal or even subnormal. Gonadal function and development may be normal or retarded in comparison with chronological age. 17-Ketosteroid excretion is not characteristic and may be low, as in adiposogenital dystrophy, normal, or high, as in adrenal cortical hyperfunction. Metabolic functions (carbohydrate, cholesterol, water, salt, and basal metabolism) as well as vascular functions (pulse rate and blood pressure) frequently show the instability characteristic of hypothalamic disorders. The prognosis in individual patients is uncertain. Patients with type Z obesity can maintain a stationary weight through adult life, can spontaneously revert to normal, or, very rarely, can come to show typical signs of adrenal cortical hyperfunction. Such forms of adrenal cortical hyperfunction are as a rule of benign nature. Among the case reports published in *Harefuah* (49:23, 1955) is that of a 54-year-old woman who during the first period of observation displayed the symptoms of frank adrenal cortical hyperfunction (weight, 244 lb. [110.7 kg.], typical distribution of the adipose tissue with bright red moon face, purple cutaneous striae, hypertension, insulin-resistant diabetes, and mild hirsutism), associated with voracious hunger and thirst. At about the same time neurological abnormalities suggestive of a cerebellopontine lesion and marked bitemporal hemianopsia developed. During a second phase the patient lost her appetite and 81 lb. (36.7 kg.), had a low blood pressure and metabolic rate, and during a third phase again showed ravenous hunger and thirst, a weight gain of about 88 lb. (39.9 kg.), a high metabolic rate, high blood pressure, and latent diabetes mellitus. A tendency toward water and salt retention was present throughout the whole period of observation. The metabolic, vascular, ocular, and neurological manifestations of the first stage disappeared following dehydrative measures. The response to dehydrative therapy suggested cerebral edema—presumably, in view of the selection and nature of the neurological manifestations, a hydrative meningitis cystica serosa of the cerebellopontine angle—as the underlying cause. The instability of the disease process is illustrated by the spontaneous development and regression of the morbid phenomena of the second phase and by the likewise spontaneous occurrence of the opposite phenomena of the third.

Occult Uterine Bleeding.—At the clinical and experimental research meeting of the Hebrew University Medical School in July, Bromberg and Bercovici described a practical method for the detection of minimal uterine bleeding by a modified benzidine test. They demonstrated the presence of occult midmenstrual bleeding in 90% of women during the reproductive period. This unexpected high incidence of midmenstrual bleeding reported in normal women may be explained by the special technique used in demonstrating the presence of minimal amounts of blood in the vagina. This method of blood detection seems to be more reliable than the vaginal smears, since red blood cells may be hemolysed in the vagina by bacteria, lysins of exfoliated cells, and the low vaginal pH. Benzidine tests yield positive results in low concentrations of erythrocytes, which are frequently missed by microscopic examinations. It is believed that the appearance of intermenstrual occult blood is closely related to ovulation. It may be considered as a more common and milder equivalent of the frank midmenstrual bleeding observed in some women and generally accepted as a sign of ovulation. The connection between ovulation and bleeding is proved by the correlative study of endometrial biopsy specimens, benzidine blood test graphs, findings at laparotomies, and controlled conceptions. The results obtained indicate that occult bleeding appears early in the postovulatory phase, most often on the 15th day of the cycle. The phenomenon described resembles the midcycle hemorrhage reported by Hartmann in monkeys and recalls the estrus phenomenon in other mammalian species, sometimes associated with genital bleeding.

Elution of Isoagglutinins.—The existence of A, B, O, and AB groups in thrombocytes, corresponding to those groups in red blood cells, has been reported by Gurevitch and Nelken of the Hebrew University Medical School, Jerusalem. The identity of the A and B antigens in platelets and red blood cells has been proved by platelet agglutination with antiserums, cross adsorption of isoagglutinins with thrombocytes and erythrocytes, inhibition of isoagglutinins with saliva from secretors, and neutralization of antiserums with A and B group specific substances. The authors' last studies dealt with investigation on eluates of antiserums adsorbed with large amounts of platelets, using the Landsteiner and Miller technique. To a platelet sediment prepared from 40 to 50 ml. of blood, 0.5 ml. of isotonic sodium chloride solution was added and the tube shaken at about 6 C to obtain a homogeneous concentrate of platelets. This suspension was added to 0.7 ml. of a high-titered antiserum in a siliconed tube and left for 15 to 20 hours at 6 C. After centrifugation, the adsorbed serum was pipetted off and the platelet sediment washed in isotonic sodium chloride solution to ensure removal of traces of serum. The washed platelet sediment was resuspended in 0.4 ml. of isotonic sodium chloride solution and shaken in a water bath at 56 C for 5 minutes. It was then centrifuged at 56 C for 1 minute and the supernatant eluate immediately removed. Using the above technique, eluates of 15 different A, B, and O serums were prepared and examined for agglutinating capacity against erythrocytes and thrombocytes.

United States Surgeons Confer with Israel Physicians.—A delegation of seven surgeons from the United States who are touring the world on a mission for the International College of Surgeons arrived in Israel recently at the invitation of the Israel section of the college and the Ministry of Health. They participated in a scientific conference held in Jerusalem under the joint auspices of the Hebrew University-Hadassah Medical School and the Israel section of the college. The visiting surgeons included Dr. Max Thorek of Chicago, Dr. Henry W. Meyerding of Rochester, Minn., Dr. Moses Behrend of Philadelphia, Dr. Nolie Mumey of Denver, Dr. W. C. Spiedel of Seattle, Dr. S. J. Carnazzo of Omaha, and Dr. E. Vovan.

Food Technology.—The importance of the new department of food technology at the Technion, the Israel institute of technology, was described by Prof. Joseph Braverman, head of the department. Previously, students wishing to take up this subject had to go abroad to study. Students in the Technion's new division of biotechnology will spend their first two years in the faculty of chemical technology and thereafter will specialize in basic processes of chemical engineering, food technology, quality testing of food, and other such subjects. The number of qualified technologists now working in Israel's food industries is about 100, and the new department plans to graduate about 10 trained food chemists annually.

Number of Medical Students Increased.—The number of students in the two final years at the Hebrew University-Hadassah Medical School is to be increased from 50 to 75. The additional 25 will comprise Israeli students returning from abroad to complete their medical studies in Jerusalem. The change is to be introduced in the academic year 1955-1956, but the classes have already been augmented by 16 Israelis who returned from the United States before the opening of the academic year.

NEW ZEALAND

Anniversary of Otago Medical School.—At a meeting of the graduates of Otago Medical School at Dunedin in February, the dean, Sir Charles Hercus, reviewed (*New Zealand M. J.* 54:120, 1955) the vicissitudes through which the school has passed. This was the second medical school to be established in Australasia, the University of Melbourne having opened its medical school in 1864. Starting with one professor and 2 students in 1875, the school has at present 9 professors, 3 assistant professors, 100 lecturers, over 100 part-time clinical teachers, and 528 students. The school also houses some 47 professorial and technical research workers for the Medical Research Council, the British Empire Cancer Campaign, the Hugh Adams Research Fund, and the Travis Trust.

Postoperative Transient Aldosteronism.—At the same meeting Dr. J. G. Llaurado reported (*Proc. Univ. Otago M. School* 33:19, 1955) on the excretion of the electrolyte-regulating corticoid after surgical trauma. The starting point of this research was the finding that in the first 24 hour collection of urine from a patient after an operation, there is an increased amount of this corticoid, associated with an inversion of the sodium-potassium ratio in the patient's urine. Believing that this corticoid is actually aldosterone, Dr. Llaurado studied 10 patients, subjected to various operations of diverse degrees of severity. In this group increased aldosterone activity (up to eight times the daily level before operation) was found in the urine of patients for several days after operation, during which the sodium-potassium ratio in the urine remained significantly reduced. There was a linear relationship between the aldosterone activity and the logarithm of the sodium-potassium ratio in the urine of patients before and after operation. Aldosterone activity in the urine receded to the preoperative level when the sodium-potassium ratio returned to its preoperative value. The clinical implication of this study seems to be that the changes in the level of aldosterone excretion, assuming that increased excretion means overproduction, are sufficient to explain the striking changes in the sodium and potassium metabolism after operation, although other factors such as protoplasmic breakdown may also account for minor losses. It was suggested that the name postoperative transient aldosteronism should be applied to such a metabolic phenomenon, since this name denotes a temporary occurrence and is consistent with the terms primary and secondary aldosteronism.

PERU

Toxicosis of Infancy.—In commemoration of the 25th anniversary of the foundation of the Peruvian Society of Pediatrics, the second Peruvian Congress of Pediatrics was held at Lima in July. Dr. C. F. Krumdieck of the National University of San Marcos said that of 12,770 infants admitted to his ward in the Children's Hospital of Lima from December, 1947, to April, 1955, 4,438 suffered from diarrhea and of these 1,350 were in a toxic state. The rest (1,214 with enterocolitis, 696 with acute dyspepsia, 266 with mild dyspepsia, and 912 with miscellaneous diseases) had only mild dehydration without significant electrolyte imbalance. Of the infants with toxicosis, only 445, or 32%, could be saved; 561 died within the first 48 hours after their admission to the hospital, mainly because they were moribund or nearly so on admission. Even so, Dr. Krumdieck believes that more infants could have been saved if the hospital had had a well-equipped service dedicated to the emergency treatment of dehydrated infants in toxic condition. Indeed a marked improvement in results has already been noted. On the other hand, most of the infants with toxicosis were poorly nourished, and this was an added factor favoring the high mortality observed. The incidence of toxicosis in infants is always much greater in the summer. Toxicosis as well as acute dyspepsia occurred much more frequently in infants over one year of age. Apart from the functional disturbances of the nervous system shown by the infants suffering from toxicosis, marked underlying anatomic lesions involving both nervous and endocrine tissue were found at autopsy in those infants who died of the condition.

Prof. Anibal Ariztía, of Santiago, Chile, said that in the last five years a marked decrease in the case fatality rate in infants with toxicosis has been obtained in his wards. He attributes this to the fact that, since 1950, emergency management of toxicity in infants has been adopted, so that as soon as the toxicosis is diagnosed specific therapy is started. This emergency therapy is handled by specially trained medical and auxiliary personnel. These successful results have been obtained despite the fact that 80% of the infants of this series were poorly nourished. Although during the last five years small doses of antibiotics have been given to most of the children with toxicosis, the author doubts that this was responsible for the good results obtained. He believes rather that the pediatrician should be cautious in the use of antibiotics because, when they are indiscriminately used, especially in babies, they may cause a severe disturbance of the intestinal flora and an increase in the diarrhea. Every effort should be made to isolate the causative organism and ascertain its drug sensitivity. The replacement of fluids and electrolytes should, if possible, be accomplished by the oral route. Fluids should never be given by vein for more than 24 hours.

Bronchopneumonia Following Measles.—At the same meeting, Dr. Carlos Bazan and his co-workers of Lima reported that, of a series of 1,159 infants suffering from contagious diseases, 337 had measles. Bronchopneumonia developed in 37. In 17 patients it was fatal. The case fatality rate increased as the infant's age diminished. Thirty-four of the infants in whom bronchopneumonia developed entered the hospital in a very poor state of nutrition. The incidence of malnutrition among the infants with bronchopneumonia was much higher than that found among those infants who did not have bronchopneumonia. It was also observed that in the poorly nourished children the measles rash tended to remain longer than usual. Apart from the classic pulmonary physical findings, fever, inspiratory dyspnea, tachycardia, anorexia, vomiting, and diarrhea were the main clinical manifestations found in the infants with bronchopneumonia. Chlortetracycline given alone or with streptomycin was the most effective drug for the control of the bronchopneumonia. Penicillin, chloramphenicol, tetracycline, and oxytetracycline were effective but to a lesser degree. Because the causative organism varies from one epidemic to another and even from patient to patient, no single drug can be recommended for routine use.

Acute Abdominal Disease.—At the same meeting, Prof. Eugenio Cienfuegos of Chile called attention to the fact that in children diverse extra-abdominal processes may simulate the clinical pattern of acute abdominal disease. The pediatrician must be aware of this in order to avoid unnecessary operations. Among such conditions rheumatic fever and pneumonia must be borne in mind. On the other hand, truly acute abdominal disease may remain undiagnosed until laparotomy reveals it to be due to intestinal parasites.

New Febrile Disease.—At the same meeting, Drs. Teodoro Taboada and Manuel Valeriano of Trujillo, Peru, described an apparently new clinical entity that they have observed with relative frequency during the last two years. Its salient clinical features are insidious onset, with slight fever, mild infection of the upper respiratory tract, and marked nervous irritability. The temperature rises to between 100 and 104 F, and hepatomegaly, splenomegaly, and discrete generalized adenopathies are detected on physical examination. Despite this the infant usually looks well. The red blood cell count ranges from 3,500,000 to 4,200,000 per cubic millimeter. There is a leukopenia, sometimes preceded by a transient, slight leukocytosis, with a differential count of 40 to 85% lymphocytes, 10 to 20% monocytes, 2 to 15% eosinophils, and 10 to 40% neutrophils. The authors believe this disease is produced by a lymphotrophic virus because the clinical findings resemble those of acute infectious lymphocytosis, infectious mononucleosis, serum hepatitis, and measles—diseases that are known to be caused by lymphotrophic viruses. None of the patients so far observed have died. Antibiotics prolong or even aggravate the disease and should be used only when intercurrent infection develops.

Congenital Cardiopathies.—Dr. Augusto Mispireta and his coworkers of the Children's Hospital of Lima at the same meeting reported that angiocardiography is the most important test for the detection of the tetralogy of Fallot and that cardiac catheterization with gasometric study is an aid to the conclusive diagnosis of persistent ductus arteriosus. In 31 of 32 children the duct was ligated, whereas, in the remaining one, section of the duct was performed. Two of the children died soon after the operation, one due to an anaphylactic reaction presumably caused by the plasma given during the operation and the other due to an intolerance of the anesthetic. In all the surviving children the clinical results have been regarded as excellent. Some have been observed for eight years following operation. Nine children with the tetralogy of Fallot underwent the Blalock operation and of these one died; this was the first child in the series. Postoperative complications were noted in only one patient in whom a hemothorax developed. Final results were good in four and fair in the remaining four. In both types of operation, antibiotics were given before and after operation.

Cortisone for Bronchitis.—At the same meeting, Dr. Alberto Steeger of Chile said that he has used cortisone as an adjuvant measure in the management of upper respiratory infections with surprisingly good results. He based this treatment on the fact that cortisone diminishes the production of inflammatory secretions and would thus prevent the obstruction of the respiratory tract. It should be given not only during the hyperergic phase of the disease but over a longer period of time whenever the intensity of the infection makes it likely that a diffuse secondary cicatricial process will develop, since cortisone also inhibits fibrosis. If cortisone is used, however, antibiotics in larger doses than usual must be prescribed to counteract the anergic effect of the hormone. If cortisone is contraindicated, antihistaminics should be given. Depressive respiratory drugs, especially opiates, must be avoided. Iodides are contraindicated because of their reflex secretory action on the bronchial mucosa.

Pulmonary Surgery in Infants.—At the same meeting, Dr. R. Matte of Chile reported a series of 138 pulmonary resections and 21 decortications. Seventy-three of the resections were performed in infants with pulmonary tuberculosis. There were eight operative deaths in this group, all of which occurred before 1954. The author believes that any infant with a primary tuberculosis that does not respond to antibiotic therapy or in which complications develop should be treated surgically. Management of the immediate postoperative period is of the utmost importance. Balls of inert plastic material were used with good results in order to prevent the displacement of the unremoved lung toward the opposite side in those patients who underwent pneumonectomy.

Lung Cysts.—At the same meeting, Dr. Simón Tisnado of Peru presented evidence to prove that most lung cysts regarded as congenital are acquired as a result of micrococcic (staphylococcic) pulmonary microabscesses (suppurative pneumonia) generally produced in the neonatal period or early in childhood. If this condition is not corrected it may lead to a pleuroparenchymal process with or without pleural empyema, or, if a bronchial fistula exists, to the formation of a pneumatocele. This latter condition may in turn lead to a pneumothorax.

SWITZERLAND

Peaceful Use of Atomic Energy.—The International Conference for the Peaceful Use of Atomic Energy in Geneva in August included a discussion of the medical problems stemming from the application of atomic energy. Switzerland has purchased an American reactor that will (1) liberate thermal energy from uranium to be used for the production of electricity in large centers, (2) produce currents of neutrons that allow the penetration of matter and the study of its structure, and (3) artificially render elements radioactive. In addition to the use of radioisotopes to determine metabolism and to diagnose and treat tumors, isotopes are now being used in plastic surgery to study revascularization in grafts; in obstetrics to localize the placental and uteroplacental vascularization; and in therapeutics to study the method of action of antibiotics. In addition to P^{32}, I^{131}, and colloidal gold, radioactive yttrium (Y^{90}) is an important therapeutic agent and has been used in the treatment of lung cancer by direct injection of particles of its oxide into the pulmonary artery. In teletherapy, a relatively new agent, radioactive cesium (Cs^{137}), has been used in England for some time. It is a fission product resulting from the combustion of uranium in a pile. Cs^{137} emits the longest gamma rays (half-life 33 years) and can serve as a source of gamma rays without having to be replaced frequently because of a decrease in activity. Already radioactive cobalt (Co^{60}) is beginning to replace roentgen rays. Prof. Tzuzuki of Japan said that blood diseases of the leukemic type continue to develop even now in survivors of the Hiroshima and Nagasaki explosions. It is difficult to ascertain the exact genetic consequences of exposure to ionizing radiations, but they do seem to constitute a significant problem. Hasterlik and Marinelli of Chicago reported the follow-up of four technicians accidently injured by reactors. They noticed changes in the leukocytes in the form of incompleteness, inclusions, and granulations. There were also temporary effects on spermatogenesis and sperm motility but none on the bone marrow, eyes, or frontal cerebral lobe function. The total daily excretion of urinary amino acids varied from 2 to 20 times (average 10 times) the normal. These qualitative and quantitative variations, occurring 12 hours after the accident, demonstrated that aminoaciduria is an early and sensitive indication of irradiation, even though no direct quantitative relationship has been found between intensity of exposure and degree of aminoaciduria.

J. F. Loutit of Harwell, England, said that malignant diseases of the blood, cancer of the skin, and cataract may result from irradiation. In animals, reduced life span and some threat to fertility have been noted. A. V. Lebedinsky of Russia studied the influence of ionizing radiation using Pavlov's method of conditioned reflexes and demonstrated a decrease in internal inhibitory mechanisms. He believes that the pathological changes occurring in the blood are due to alterations in the neuroendocrine forces that make up the general adaptation syndrome. He showed that changes appear early in the electroencephalogram, even after exposure to relatively weak doses of radiation, such as those administered during a course of treatment with P^{32}. In Russia radiotherapy is accomplished by means of a teletherapy apparatus with Co^{60}, which can give out charges of up to 400 curies. Other communications dealt with the radioactivity of air, water, and earth, which has been notably elevated in various parts of the globe during the last few years, exposing an ever-increasing portion of the world population to the harmful effects of radiation.

Dr. Sievert described the attempt made in Sweden to determine the value of natural radioactivity of various parts of that country and to measure the natural radioactivity of living things, especially men. Such studies are indispensable for correct determination later of the increase in general radioactivity. In Switzerland, a committee has recently been set up to curb undue anxiety in the population of Geneva and to study radioactivity of the atmosphere, establish its causes, and specify what dangers it entails. From determinations already made, it would seem that the radioactivity of the earth around Geneva has substantially increased since 1947. The additional radioactive substances would appear to be of atmospheric origin. If the development of atomic energy entails only a feeble artificial radioactivity that is much less than that occurring naturally, the danger can be considered to be negligible. This is not so if the radioactivity produced is equal or superior to that occurring naturally. A significant increase in the present radioactivity of the air, water, and land will probably lead to a greater frequency of natural mutations, causing an increase in the number of hereditary malformations within a few generations. A map of the radioactivity of the earth's surface is needed. The World Health Organization and the International Labor Organization will collaborate in this work.

Fight Against Bovine Tuberculosis.—At the end of 1954, 68.2% of the 162,000 herds in Switzerland were free from tuberculosis. Application of new legislation is expected to eradicate the bovine form of the disease completely by 1958. Prof. G. Fluckiger, director of the Federal Veterinary Office in Bern, estimates that the annual loss caused by bovine tuberculosis is 20 million Swiss francs. Formerly, in Switzerland, 8 to 10% of cases of human tuberculosis were caused by Mycobacterium tuberculosis bovis. It is estimated that the loss to the Swiss economy caused by human tuberculosis varies between 130 and 150 million Swiss francs a year (compared with 780,000 francs lost as a result of bovine brucellosis). Human tuberculosis of the bovine type no longer exists in regions where tuberculosis has been systematically eliminated in the herds, and thus, in the future, a saving of about 12,500,000 francs can be expected in the expenses of the campaign against tuberculosis in human beings. Up to the end of 1954, about 200,000 head of tuberculous cattle were slaughtered. Since the indemnity for each animal that must be eliminated is no more than 80% of its value, the loss to owners of livestock was about 40 million Swiss francs.

Hematological Changes in Gastric Cancer.—While the classic descriptions of gastric cancer include anemia, leukocytosis, and polynucleosis, frequently one or more of these are not present. J. Gelband and his co-workers (*Helvet. med. acta* **22**:156, 1955) studied the hematological changes accompanying gastric cancer in 450 hospitalized patients (257 men and 193 women). There were 444 carcinomas and 6 primary mesenchymal tumors of the stomach. In 335 instances, the diagnosis was verified at autopsy or operation. More often than not there is no reduction of hemoglobin level or there is a discrete anemia, hardly greater than that seen in most subjects past 45 years of age. Pronounced anemia is the exception in gastric cancer. Furthermore, anemia in gastric cancer is less often hypochromic than was believed. The colorimetric index was more than one in 25% of these patients. Less than 18% had an index of less than 0.8. Leukocytosis is less common than was believed, but polynucleosis is the commonest hematological anomaly in cancer of the stomach.

TURKEY

Congenital Osseous Polydystrophy.—In the *Bulletin of Istanbul University Medical Faculty* (vol. 14, no. 1), Prof. I. H. Alantar reported a case of eccentro-osteochondrodysplasia in a 5-year-old boy. The first of his four siblings lived only four days; the second died of miliary tuberculosis; the third, a premature birth, was stillborn; and the fourth died soon after birth. Other members of this family had no somatic abnormalities, but an uncle is undersized. When the patient was 8 months old, he was still unable to move his limbs and he was treated for rickets without benefit. He began moving his limbs when well over a year old. His first attempt at walking was when he was two, and only when he was three was he able to walk slowly and then with difficulty. When he was between 18 months and 2 years of age there was complete arrest of development. On admission he weighed 8,000 gm. (17.6 lb.) and measured 70 cm. (2 ft. 3.6 in.), the normal length of a 10-month-old child; his fontanelles were closed; he had the flattened head of one with rickets; and there was a mild prognathism. He had an intelligent face and answered questions sensibly. There was marked hypotonia. His fingers were short, and his wrists were seemingly without bone. He could easily touch the back of his head with his feet. He had a swaying gait and propped his hands on his knees to prevent falling. Rachitic scoliosis was marked. His extremities were long in relation to his body, and there was bilateral genu valgum. His feet were unusually soft and flat, and he had bilateral dislocation of the hip. He had a few carious teeth; his larynx was underdeveloped; and he had ectopic testes. He had a symmetric rachitic pelvis and deformed extremities. His head was normally formed but had the measurements of the head of a 12-month-old child.

His Pirquet test and serologic tests for syphilis were negative. A roentgenogram showed normal fontanelle sutures, a large hypophysis, and a large sella turcica. The head of the humerus was rarified and partly destroyed; the calcification of the radius, ulna, and the metacarpal phalanges was that of a newborn child. The head and greater trochanter of the femur and the pelvis were underdeveloped, and the acetabulum was deformed. The lower epiphysis of the femur was irregular and contained little calcium. The metatarsal phalanges had the structure of those of a 3-month-old child. There was dorsal and dorsolumbar scoliosis. The vertebral bodies were flattened. In the region of the sternum an ossiferous protuberance was seen. The lower ribs were shovel-shaped and very thin. The patient had normal intelligence. Although he was treated with ultraviolet light, vitamin D_2, and Anteron (a hormone), there was no change in his condition.

Hypochromic Anemia.—In *Klinik* (vol. 9, no. 6) Demirag and Cura reported the results of intravenous iron therapy in 13 children with hypochromic anemia. The patients were 1 to 8 years old. On admission their erythrocyte counts were 1,200,000 to 3,400,000 per cubic millimeter; their leukocyte counts were 2,300 to 5,600 per cubic millimeter; their hemoglobin levels were 2.9 to 6.0 gm. per 100 cc.; their reticulocyte counts were 0.5 to 1.3%; and their hematocrits were 8 to 26. They received a daily intravenous injection of Ferronascine (ferri-dia-dioxy-B1 B dimethyl sodium butyrate) containing 20 mg. of iron. On admission the erythrocyte count of one patient, who had had malaria for two years, was 2,700,000 per cubic millimeter. After six weeks of treatment it was 4,100,000; hemoglobin level rose from 3.2 to 9.7 gm. per 100 cc.; reticulocyte count fell from 4.5 to 2.6%; and the hematocrit increased from 29 to 32. The erythrocyte count of another patient with malnutrition was 3,700,000 per cubic millimeter on admission, and after treatment for five weeks it was 4,800,000; hemoglobin level rose from 5.9 to 9.7 gm. per 100 cc.; reticulocyte count increased from 1 to 14%; and hematocrit increased from 10 to 27. Within 25 days the average increase in erythrocyte count was 1 to 2 million and in hemoglobin level 3 to 4 gm. per 100 cc. Ferronascine did not greatly affect the leukocyte count. In most of the patients it was from 5,400 to 7,600 per cubic millimeter following treatment. Ferronascine was well tolerated, and no untoward side-effects were observed.

CORRESPONDENCE

COBALT AND THYROID FUNCTION

To the Editor:—We wish to take issue with some of the conclusions in the articles concerning the effects of cobalt on thyroid function that appeared in The Journal of Aug. 13, 1955, pages 1347 to 1357. In addition, we wish to describe further experiences since our observations (*J. A. M. A.* 157:117-121 [Jan. 8] 1955) that led us to conclude that cobalt is a goitrogen in man. Our reasons for so concluding are worthy of emphasis. 1. Hyperplastic goiters and hypothyroidism were observed to develop during administration of cobalt. 2. Tests of thyroid function showed evidence of marked suppression of normal activity during drug therapy. 3. Clinical and laboratory recovery occurred after withdrawal of cobalt.

Holly (on page 1349 of the Aug. 13 issue) purports to present "complete investigations in animals and pregnant women." Of the group of 78 pregnant women, 58 patients are apparently the same group already reported by Holly (*Obst. & Gynec.* 5: 562-568 [April] 1955) and presented in Chicago in December, 1954. It is common knowledge that a goiter easily may escape detection if the examiner does not specifically palpate for the organ. Holly states that "no thyroid enlargement was noted in patients receiving cobalt." At the same time, in not a single one of his 78 patients was any thyroid function test reported, thus causing us to wonder if the examiner was "goiter-conscious" at the time the cases were studied. Jaimet and Thode (on page 1353) describe extensive thyroid function studies in 18 children. Of this group, nine patients received cobalt in a dosage below that which had been given in our cases. Of the nine patients who did receive cobalt in dosage comparable to ours, three showed a reduction of thyroid function after an initial course of cobalt therapy, two of them strikingly so. The authors chose to disregard these cases because a second course of therapy failed to cause a similar suppression. We believe the failure to reproduce the suppression of function may be related to the rebound recovery phase of thyroid function that occurs after withdrawal of a thyroid suppressant, and we consider the exclusion of the data on these cases unwarranted. The reduction of iodine uptake that they observed was similar to that which we reported and also to the independent observations of Keitel (*J. A. M. A.* 158:1390 [Aug. 13] 1955).

Both Holly and Jaimet and Thode infer that our observations of goiter in cobalt-treated patients may have been due to coincidence. They should not overlook an important point that we emphasized in our report, viz., not only were goiters observed to develop in patients receiving cobalt but the goiters disappeared when cobalt therapy was discontinued. This observation has been confirmed by Gairdner, Marks, and Roscoe (*Lancet* 2:1285 [Dec. 18] 1954), who reported goiter and failure to thrive in a premature infant receiving cobalt, and McBryde (*A. M. A. Am. J. Dis. Child.* 88:503 [Oct.] 1954), who reported goiter in a premature infant receiving Roncovite, a cobalt-iron preparation. Klinck (on page 1347) reports on 10 patients with thyroid hyperplasia, of whom 5 had been given cobaltous chloride, but he is unwilling to implicate cobalt as a cause of thyroid hyperplasia. The patients were apparently an unselected group from widely separated parts of the country. A statistical calculation of the binomial confidence limits shows, with 95% confidence, that in order for 5 cobalt-treated out of 10 cases of goiter to occur by chance, it would be necessary that a minimum of 18.7% (and a possible maximum of 81.3%) of the population from which these cases were drawn had received cobalt. Such a figure far exceeds prudent estimates of the drug's actual use; we, therefore, view Klinck's findings as strong support of the thesis that cobalt is goitrogenic.

In addition to the reported cases referred to above, we have received communications concerning 14 cases of goiter and/or thyroid dysfunction in cobalt-treated patients. Of these, 10 patients were infants, 4 of whom were premature; 2 patients had renal disease; and 2 had Mediterranean anemia. None of these had sickle cell anemia. We have good reason, therefore, for believing that our findings are not solely and specifically related to sickle cell anemia. Eight of the cases were observed while the patients were receiving Roncovite, thus indicating that the addition of iron to cobalt does not protect against the goitrogenic effect of cobalt. Since hypothyroidism is more injurious to the health of infants and children than to adults, we are of the continuing opinion that indiscriminate use of cobalt salts should be particularly avoided in this young age group. Our caution is especially appropriate in view of the recent communication from the editorial board of *Blood* (10:852 [Aug.] 1955). After interrogation of 17 acknowledged experts in hematology on the use of cobalt preparations, the moderator, William Dameshek, summed up: "It seems well-nigh unanimous from the above comments that cobalt has little if any value in the clinical management of anemia. Even in the anemia of chronic nephritis for which some beneficial results have been claimed, although there may be slight improvement in red cell values, there is probably little if any clinical benefit for the patient. Our experience with cobalt in the treatment of hypoplastic anemia and other instances of bone marrow failure has been almost uniformly disappointing. In iron deficiency, there seems little if any indication for using anything other than iron, which has such striking value. Because of the almost complete unanimity of the panel in this regard and because of possible toxicity of cobalt in some patients, it seems unwise to recommend cobalt alone or cobalt with iron to the medical profession, although of course one might continue its use as an experimental material under certain circumstances."

ADENOMA SEBACEUM

To the Editor:—In the article "The Cardiologist Looks at the Skin" in The Journal, July 9, 1955, page 821, Silverman and Bernstein state that adenoma sebaceum "is a nevoid disorder in which involvement of the sebaceous glands is a feature." We are in disagreement with this statement. Our recent studies at Rosewood State Training School, Owings Mills, Md. (*Maryland M. J.* 3:607-611 [Nov.] 1954) were in agreement with those of Butterworth and Wilson (*Arch. Derm. & Syph.* 43:1-41 [Jan.] 1941). Adenoma sebaceum is a misnomer, since histological sections of this condition are singularly devoid of sebaceous gland hyperplasia; on the other hand, there is evidence of fibrous hyperplasia. Drs. Silverman and Bernstein have, however, done a superb job in their presentation and again stress the adage that "the skin may act as a mirror of internal disease."

CARDIOPERICARDIOMYOPEXY

To the Editor:—In The Journal, Aug. 20, 1955, page 1459, in the Foreign Letters section under France, the abstract of my article has a few errors. The title should be "Cardiopericardiomyopexy." The operative mortality rate in angina pectoris is 5% and not 10% as reported. These operations were performed in New York City, and I believe that it be appropriate to mention it in order not to create the impression that they were performed in France.

MEDICAL FILM REVIEWS

Toxemia of Pregnancy: 16 mm., color, sound, showing time 29 minutes. Prepared by M. S. Assali, M.D., S. T. Gerber, M.D., and R. D. Bryant, M.D., University of Cincinnati College of Medicine and Cincinnati General Hospital. Sponsored by Irwin Neisler Company, Decatur, Ill. Produced in 1955 by and procurable on loan from Mervin LaRue, Inc., 159 E. Chicago Ave., Chicago 11.

Toxemia is defined as an acute vascular complication of pregnancy characterized by generalized arteriolar vasoconstriction, edema or albuminuria or both, and sometimes by convulsions and coma. The vasoconstriction is considered to be humoral rather than neurogenic in origin. The effects of the vasoconstrictor substance on blood vessels and secondarily on the brain, kidney, and uterus are illustrated by animated drawings. This medium is also used to demonstrate the rationale of using a vasodilating drug (Veratrum viride) in the treatment of toxemia. The method of treatment used at the Cincinnati General Hospital is outlined, and the results in the treatment of eclampsia in over 200 consecutive cases since 1930 are given. The film mentions that toxemia accounts for one-third of all maternal deaths in the United States. It should be said that it is one of the three most common causes of maternal mortality along with hemorrhage and sepsis, these three producing about 50% of the deaths. It is not the leading cause of fetal mortality. The impression is given that the eyeground findings are very valuable for diagnosis and prognosis; however, this would be questioned by some. The film gives the authors' concept of vasoconstriction, which not everyone would agree with. Nevertheless, the film should be of considerable general interest. This method of treatment should be considered very carefully before there is widespread adoption of it, because the authors are treating a symptom instead of a disease and this should be clarified. The photography, animation, and narration are very well done.

Too Young to Burn: 16 mm., color, sound, showing time 26 minutes. Prepared by Harry F. Dietrich, M.D., Beverly Hills, Calif. Produced in 1954 by Sid Davis Productions, Hollywood, Calif., for the Federation of Mutual Fire Insurance Companies, Chicago. Procurable on loan from Modern Talking Picture Service, 140 E. Ontario St., Chicago 11, or regional offices of Modern Talking Picture Service.

The purpose of this film is to cause parents to think about safeguarding their children from fire and to cause them, as a result of their thinking, to teach fire safety correctly to their children. It sets forth the concept that the absolute parental protection of children from accidental injury from early infancy must be replaced later through the preschool years by education. This point is illustrated by several scenes in which accidental burns of a minor nature are used by parents as an educational experience. The film contains much negative teaching, which is not too effective, and the pace is too slow to maintain interest, particularly in the first half of it. It would be more effective if the points made were concentrated into approximately half the time. The film is intended primarily for parents of infants and preschool children and would also be suitable for any groups concerned with accident prevention, particularly in the home and in regard to children, and to special groups of upper high school and college age who are studying community problems and accident prevention.

NEW FILMS ADDED TO A. M. A. MOTION PICTURE LIBRARY

Surgical Approaches to the Elbow Joint: 16 mm., color, sound, showing time 37 minutes. Prepared by LeRoy C. Abbott, M.D., University of California. Produced in 1950 by Churchill-Wexler Film Productions, Los Angeles, for the Veterans Administration. Procurable on loan (service charge $3) from Committee on Motion Pictures and Medical Television, American Medical Association, 535 N. Dearborn St., Chicago 10.

This motion picture combines the surgical and anatomic approaches to the elbow joint. Skillful blending of animated drawings with an anatomic review based on demonstration of the parts in the living subject precedes the surgical approach. A desirable educational feature of the film is the reiteration and summarization of the essentials of a given section after they are first pictured and described. (A complete review of this film appeared in the Feb. 24, 1951, issue of THE JOURNAL, page 584.)

Surgical Approaches to the Spine and Sacroiliac: 16 mm., color, sound, showing time 27 minutes. Produced in 1953 by Churchill-Wexler Productions, Los Angeles, for the Veterans Administration. Technical adviser: LeRoy C. Abbott, M.D., University of California. Procurable on loan (service charge $3) from Committee on Motion Pictures and Medical Television, American Medical Association, 535 N. Dearborn St., Chicago 10.

The surgical approach to the joint is demonstrated by use of a cadaver, the steps in the procedure being shown by diagram. The approach to the lumbar aspect of the spine is also illustrated by an operation on a cadaver, with a recapitulation in animation that clarifies the steps in the procedure. (A complete review of this film appeared in the April 23, 1955, issue of THE JOURNAL, page 1580.)

Surgical Approaches to Joints of the Wrist: 16 mm., color, sound, showing time 33 minutes. Produced in 1951 by Churchill-Wexler Productions, Los Angeles, for the Veterans Administration. Technical adviser: LeRoy C. Abbott, M.D., University of California. Procurable on loan (service charge $3) from Committee on Motion Pictures and Medical Television, American Medical Association, 535 N. Dearborn St., Chicago 10.

Animated diagrams depict the bones, ligaments, muscles, tendons, and neurovascular structures with which the surgeon deals in various approaches to the wrist. The sections on anatomy are followed by operations employing approaches to the volar, radiovolar, ulnar, and dorsal aspects. (A complete review of this film appeared in the Nov. 29, 1952, issue of THE JOURNAL, page 1338.)

Disaster Anesthesia: 16 mm., color, sound, showing time 35 minutes. Prepared by Max S. Sadove, M.D., and Lloyd A. Gittelson, M.D., University of Illinois College of Medicine. Produced in 1952 by Scientific Film Company, Berwyn, Ill., for E. R. Squibb & Sons. Procurable on loan (service charge $4) from Committee on Motion Pictures and Medical Television, American Medical Association, 535 N. Dearborn St., Chicago 10.

This is a civil defense training film for teaching dentists and physicians to act as anesthetists for emergency duty in case of disaster. A technique is shown for administering general anesthesia safely and efficiently to huge groups of injured people with improvised equipment and shelter. In general, this film is well planned; however, the subject of resuscitation should be emphasized a little more in detail. In the use of premedication, a warning about dosage should be given so that overdoses will not be administered. This film is recommended for showing to all physicians.

Principles of Respiratory Mechanics: Part I: 16 mm., color, sound, showing time 22 minutes. Prepared by Edward P. Radford, M.D.; Jere Mead, M.D.; Malcolm McElroy, M.D., Department of Physiology, Harvard School of Public Health; and Matilda C. Smith, National Foundation for Infantile Paralysis. Produced in 1955 by Science Pictures, Inc., under a grant from the National Foundation for Infantile Paralysis. Procurable on loan (service charge $1) from Committee on Motion Pictures and Medical Television, American Medical Association, 535 N. Dearborn St., Chicago 10.

This film illustrates the mechanical behavior of the lungs in normal and pathological states. Utilizing for illustration normal subjects, patients with respiratory conditions, and animated drawings, the film deals with such basic concepts as elastic and resistive properties of the lungs and pressure-volume relationships. An unusual feature is the use of a transparent respirator of the Drinker type that should be extremely valuable for purposes of instruction and research. The main value of the film lies in the actual photographs of the volunteer subjects and in the animated diagrams. However, the diagrams may be criticized for portraying the up and down movement of the diaphragm as a succession of jerks and for not showing accurately the movement of the lungs at the costophrenic angles. This film should be of interest to medical students in a course of respiratory physiology and also to students in special courses on the care of patients with poliomyelitis. The color photography, animated sequences, and narration are excellent.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

The Diagnosis of Tricuspid Stenosis. W. Whitaker. Am. Heart J. 50:237-241 (Aug.) 1955 [St. Louis].

The blood pressure records obtained by catheterization of the right side of the heart from one patient with a normal tricuspid valve and from three patients with mitral stenosis and tricuspid stenosis are described. Of the three patients with tricuspid stenosis, two had tricuspid stenosis and sinus rhythm, and their records showed an abnormally high auricular pulse pressure that was not transmitted to the ventricle and a higher diastolic blood pressure in the auricle than in the ventricle. The record of the third patient with tricuspid stenosis showed no auricular pulse, since the patient had auricular fibrillation, but there was an abnormal diastolic blood pressure gradient between right auricle and ventricle similar to those recorded in the two patients with sinus rhythm. A rise in auricular blood pressure of about 5 mm. Hg during ventricular systole suggested that there was also slight tricuspid incompetence in the patient with auricular fibrillation, and this was confirmed at operation, when a stream of blood was felt regurgitating through the stenosed tricuspid valve during ventricular systole. Thus in all three patients with an abnormal tricuspid valve, the auricular blood pressure was higher than the ventricular pressure during ventricular systole. This abnormal pressure gradient across the tricuspid valve appears to be the most valuable sign of tricuspid stenosis. Abnormally high auricular pulse pressures, which were not transmitted to the ventricle and which were present in the two patients with sinus rhythm, were manifested clinically as a giant "a" wave in the jugular venous pulse and as a presystolic hepatic pulsation. The limitations of this clinical sign are, first, that it is lost when auricular fibrillation develops (as occurs in many patients with tricuspid stenosis) and, secondly, that when there are signs of pulmonary hypertension it is impossible to decide whether giant "a" waves are a manifestation of tricuspid stenosis or of pulmonary hypertension. The giant "a" waves are a valuable sign of tricuspid stenosis only when they occur without other signs of complicating pulmonary hypertension, such as a lift over the right ventricular outflow tract, a palpable pulmonary second heart sound, right ventricular hypertrophy in the electrocardiogram, and abnormally prominent pulmonary arteries on radiological examination.

Eisenmenger's Complex. J. W. Brown, D. Heath and W. Whitaker. Brit. Heart J. 17:273-284 (July) 1955 [London, England].

Brown and associates describe observations on seven patients with Eisenmenger complex. This is a clinical rather than an anatomic diagnosis, appropriate for patients with cyanotic congenital heart disease with pulmonary hypertension and an overriding aorta. The symptoms and signs associated with this anomaly are characteristic but not diagnostic of it, since they occur in other forms of cyanotic congenital heart disease with pulmonary hypertension. Breathlessness on exertion, hemoptysis, and chronic cough were the common symptoms. Hoarseness and aphonia did not occur in the present series. The only physical signs common to this group of patients, other than cyanosis, were those of pulmonary hypertension. Cyanosis developed during adolescence except in one patient, in whom it was present from birth. Four patients had no murmurs. A parasternal systolic murmur is not an essential feature. On electrocardiographic examination there was evidence of right ventricular dominance in all patients except one who had also systemic hypertension. On radiological examination there was evidence of right ventricular hypertrophy and dilatation of the pulmonary arteries, which was not of the extreme degree usually considered characteristic of Eisenmenger complex. Angiocardiography was the most important diagnostic investigation, since it demonstrated the overriding aorta. Cardiac catheterization confirmed the presence of pulmonary hypertension. The anatomic components of Eisenmenger complex have been defined as a high ventricular septal defect in the membranous part of the septum, dextroposition of the aorta so that it arises from both ventricles above the septal defect or from the right ventricle alone, absence of pulmonary stenosis with a normal or dilated pulmonary artery, and characteristic changes in the pulmonary vascular tree. The pathological features that may occur in a patient fulfilling the criteria for a diagnosis of Eisenmenger complex in life include at one extreme a ventricular septal defect with pulmonary hypertension, right ventricular hypertrophy, and an overriding aorta and at the other extreme a moderate degree of transposition of the great vessels. Recognizing this, Lev in 1953 subdivided Eisenmenger complex anatomically into Eisenmenger complex with overriding aorta and the Eisenmenger type of transposition, as in one patient of the present series, who had an abnormal origin of the coronary arteries. On histological examination, medial hypertrophy and intimal changes in the pulmonary arteries and arterioles, which occur in other forms of congenital heart disease with pulmonary hypertension, are also characteristic of Eisenmenger complex.

Age and Sex Factors in Coronary Artery Disease. A. A. F. Peel. Brit. Heart J. 17:319-326 (July) 1955 [London, England].

The investigations in the course of which the present observations were made were originally begun to assess the immediate and remote prognosis in patients who have had an acute coronary episode and do not include cases of chronic angina of effort which started so insidiously and progressed so slowly that no definite episode could be recognized. The patients were seen in consulting practice, and the material therefore includes a wider range of severity than series of hospital admissions. Analogous cases referred to the outpatient department or admitted to the cardiac wards of the Victoria Infirmary, Glasgow, Scotland, between January, 1951, and December, 1953, were also studied. The average incidence of coronary attacks was compared in men and women in a series of 865 cases. The overall proportion of males to females was four to one. This ratio varied in different age groups. The youngest male was aged 28, and there were several between this age and 43, which was the age of the youngest female. Below age 50 the ratio of males to females was 7 to 1; between 50 and 59 it was almost 10 to 1. From 60 to 69 the ratio had dropped to just over four to one, while from 70 onwards it was under two to one. Coronary artery disease starts earlier in men, reaches a peak at age 55 to 59 and thereafter falls steeply. In women the rise in incidence is slow and steady from age 40 to age 70; there is no ultimate fall in incidence comparable to that seen in men. The immediate mortality in 276 cases of cardiac infarction, which were treated before anticoagulants were adopted, was analyzed in relation to age and sex. In men the mortality rose steadily from 5% at ages under 44 to 35% at ages over 65; in women the mortality is approximately 25% in all age groups, rising only slightly as age advances. The long-term prognosis was studied in 240 survivors from cardiac infarction and 129 survivors from attacks of cardiac ischemia. The best expectation of life was

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1946 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

found in men aged 50 to 54 who fared better than younger men; the worst expectation was at age 60 to 64. In women the expectation was best at ages below 50 and diminished progressively as the age at onset increased. Information available on deaths showed that almost one third of the deaths occurred in a second or subsequent attack, and these deaths are spread over the ensuing years being only a little more common in the first than in later years. Cardiac failure accounted for nearly another third, but most of the deaths from this cause occurred within the first year. One death in every five occurred quite suddenly while the patient was engaged in his usual daily routine; these deaths again were perhaps a little more common in the first and third than in other years. The author feels that deaths from bronchial carcinoma soon after coronary thrombosis or cardiac infarction seem much too high to be purely accidental. The original coronary thrombosis may have been an early symptom of the developing bronchial carcinoma.

Specific Therapy for Salicylism. G. E. Schreiner, L. B. Berman, J. Griffin and J. Feys. New England J. Med. **253**:213-217 (Aug. 11) 1955 [Boston].

This report concerns studies carried out on two patients poisoned with acetylsalicylic acid (aspirin). The first patient, a man aged 44, was found unconscious in his room. Seven empty aspirin bottles were found, and it was estimated that he had ingested 210 gm. of aspirin. Since the patient's clinical appearance raised considerable doubt as to spontaneous recovery, dialysis on a Kolff artificial kidney was begun seven and one-half hours after admission. After one hour, respiration was more quiet; after two hours the patient was awake, attempting to speak, and able to drink water, and by the third hour he was speaking rationally. The procedure was carried out for a total of six hours, with a mild hypotension (blood pressure of 80/60 mm. Hg) as the only untoward effect. The patient denied any suicide attempt but stated that he had obtained seven bottles of aspirin about eight weeks before admission and had begun to take them for headaches, at first 5 tablets a day, gradually increasing to 50 tablets a day. This gave him a pleasantly drowsy feeling along with blurred vision, diminished auditory acuity, sweating, and occasional headache. On the day before admission he had taken no more than the usual amount but had combined it with Coca-Cola. He had felt faint toward the evening before admission and then remembered no more until he awakened during the dialysis. The second patient was a 19-year-old woman who had a history of an earlier suicide attempt with aspirin. On Sept. 16, she had dissolved "1 bottle" (83 gm.) of aspirin in a glass of water and had drunk about "half." She was seen at another hospital four hours later, and a gastric lavage was performed. She was then discharged. Later that evening she began to complain of difficulty in hearing and was returned to the same hospital at 10:00 a. m. on Sept. 17, awake, hyperpneic, restless, and partially deaf. She was transferred to Georgetown University Hospital, where, on admission, she was drowsy but oriented. Speech was slurred, and she complained of a roaring sound in her ears. Physical examination revealed flushed facies, a hot, dry skin and deep, irregular respirations at 36 per minute. The blood pressure was 110/50 mm. Hg; the pulse rate was 100 per minute and the temperature 99.8 F (37.7 C) by rectum. Because approximately 30 hours had elapsed since the ingestion of aspirin without loss of consciousness, conservative management was considered justified, and intravenous administration of fluids and sodium lactate was started. The course over the next six days was one of progressively severe mental disturbance, including visual hallucinations and maniacal behavior, which reached their peak on the fourth day. She abruptly reverted to normal behavior on the fifth day and was discharged, asymptomatic, one day later. The authors emphasize the value of the artificial kidney in quickly removing salicylates from the body. In an addendum the authors mention two other cases of salicylism due to the ingestion of aspirin (132 gm. in one and 166 gm. in the second patient). The first died on admission nine hours after ingestion. The second patient was admitted 16 hours after ingesting 166 gm. A blood level of 115 mg. per 100 cc. was reduced to 29 mg. by a seven hour dialysis, and the patient awakened and had a complete recovery of reflexes and faculties. However, multiple coagulation defects, with gastrointestinal hemorrhage, developed; she received 10 liters of blood but died five days later with generalized purpura and anuria.

Treatment of Asthma by Corticotherapy: Based on Ninety-Five Cases. P. Vallery-Radot, C. Laroche and G. Lyon. Presse méd. **63**:1043-1045 (July 16) 1955 (In French) [Paris, France].

The authors treated 95 patients with severe asthma with corticotropin, cortisone, or hydrocortisone. The effects of the three hormones are highly similar. Rapid sedation of symptoms was obtained in 80 patients. Of the 15 patients in whom therapy failed or proved unsatisfactory, 4 died. Necroscopic examination showed the usual lesions of status asthmaticus. The long-term results were variable; only 10 patients gained benefit from corticotherapy for more than six months. Prolonged treatment, from two months to three years, was practiced in 16 patients and was successful in 12 of them. There were three complete failures and one fair result. Dosage in these patients ranged from 50 to 100 mg. of corticotropin or cortisone each day. There is no means of judging the individual patient's chances for successful treatment in advance, since the result seems to be independent of age, severity, or duration of disease, and whether the asthma stems from an allergy or a bronchial superinfection.

Incidence of Amebiasis in Healthy Individuals, Clinic Patients and Those with Rheumatoid Arthritis. R. E. Rinehart and H. Marcus. Northwest Med. **54**:708-712 (July) 1955 [Seattle, Wash.].

Comparative studies of the efficiency of various methods of preserving and staining stool specimens for the identification of trophozoites and cysts of Endamoeba histolytica showed that examination of a wet preparation, stained with dilute iodine solution, preferably after concentration, is the most sensitive method for detection of the cystic forms of E. histolytica. One hundred stool specimens obtained from four persons, each of whom had been negative for E. histolytica on at least 12 previous examinations, were examined with the iodine staining method; 2 of the 100 specimens were reported to contain unidentified cysts and 98 as "no parasites found," giving a presumptive false positive rate of less than 2% for a single examination. Thus, in competent hands, the iodine staining method does not give rise to extensive false positive reports. Stool specimens from 146 normal medical students, from 150 clinic patients selected at random but with the exclusion of patients with rheumatoid arthritis, and from 150 patients with rheumatoid arthritis were examined. Results showed that six stool examinations, at intervals of two or more days, will establish the diagnosis in 95% or more of the persons infected with E. histolytica. A single examination will detect from 40 to 60% of those infected. Approximately 30% of normal persons living in Oregon are at any one time subclinically infected with E. histolytica. A similar incidence was found in persons with a wide variety of illnesses. Ninety-five per cent of the patients with rheumatoid arthritis were infected with E. histolytica.

Infection with Drug-Resistant Tubercle Bacilli. F. Beck. Am. Rev. Tuberc. **72**:151-157 (Aug.) 1955 [New York].

Of 600 patients with newly diagnosed pulmonary tuberculosis who had been admitted to the State Tuberculosis Hospital in Ray Brook, N. Y., since 1948, tubercle bacilli were cultured in 480. Drug-susceptibility studies revealed that only 10 of the 480 patients had been infected with drug-resistant tubercle bacilli. The presumptive source of contact could be established in all but two of these. The strains of tubercle bacilli were primarily resistant to streptomycin in eight patients and to streptomycin and aminosalicylic acid (PAS) in two patients. Of these 10 patients, one did well without chemotherapy and 8 made satisfactory recoveries after multiple drug therapy, which included streptomycin. Only the 10th and most recent patient had an unfavorable prognosis. Infection with drug-resistant tubercle bacilli in such a small ratio of patients is not likely to become a serious public health problem. Most of the patients with this type of infection were treated successfully, because of the availability of several effective chemotherapeutic agents.

The Prevalence of Streptomycin- and Isoniazid-Resistant Strains of Mycobacterium Tuberculosis in Patients with Newly Discovered and Untreated Active Pulmonary Tuberculosis. A. D. Chaves, A. B. Robins, H. Abeles and others. Am. Rev. Tuberc. 72:143-150 (Aug.) 1955 [New York].

Between July, 1953, and January, 1955, culture studies were carried out on 24 hour sputum specimens obtained from 898 untreated patients with newly reported active and newly reactivated pulmonary tuberculosis who had been registered from the 23 chest clinics of the state of New York. Mycobacterium tuberculosis was isolated from the sputums of 385 (43%) of these patients. The patient-strains of tubercle bacilli were tested for susceptibility to streptomycin and isoniazid by the direct method. In 342 (89%) of the 385 patients, the strains of Mycobacterium tuberculosis were completely susceptible to both streptomycin and isoniazid. Of the remaining 43 patients (11%) from whom strains were isolated that showed any degree of resistance to either drug, only 6 (1.6% of the total) had strains significantly resistant to streptomycin and only 9 (2.3% of the total) had strains significantly resistant to isoniazid. None of the patients had organisms that were significantly resistant to both drugs. While strains of tubercle bacilli resistant to streptomycin and isoniazid thus were demonstrated in the sputum of a small number of chest clinic patients with newly discovered and untreated active pulmonary tuberculosis, this does not, at present, represent a serious public health problem.

Autoerythrocyte Sensitization: A Form of Purpura Producing Painful Bruising Following Autosensitization to Red Blood Cells in Certain Women. F. G. Gardner and L. K. Diamond. Blood 10:675-690 (July) 1955 [New York].

Gardner and Diamond describe the occurrence, in four women, of an abnormal response to bruising, characterized by local pain, swelling, and extension of bleeding into adjacent areas. The first of the four cases concerned a 44-year-old nurse, who 20 years before had been struck by an automobile and had suffered a fracture of the skull with concussion and a fracture of the pelvis, with multiple abrasions, contusions, and ecchymoses of the lower extremities. Two months later her physician observed that her right knee remained stiff and had a persistent ecchymotic area. The knee joint was explored surgically and a hematoma removed from the patellar bursa. However, the ecchymotic areas around the knee persisted, and the patient began to have painful swelling and ecchymoses around the ankle. At this time, she was seen by one of the authors of this report. Studies on her blood yielded normal results. A wide variety of medical treatments were ineffective. A splenectomy was done in an effort to improve the bleeding tendency and to control the ecchymotic lesions. Following splenectomy the skin lesions were absent for a three year period but then reappeared. Associated with the skin lesions, the patient has had two episodes of cerebral hemorrhage and repeated bleeding from the gastrointestinal and genitourinary tracts without known trauma. Multiple symptoms suggest that the patient may have a diffuse vascular defect as well as an abnormal tissue response to extravasated red blood cells. During the first 15 years of her illness, her painful ecchymotic lesions were initiated by trauma. In later years, "physiologic trauma" appears to have been adequate to initiate the abnormal tissue reaction. The use of whole blood injections to control the painful lesions is of interest, for certainly one would anticipate further sensitization from the procedure, but some "desensitization" and temporary benefit seemed to result. After presenting the histories of the other three patients, the authors describe skin test procedures carried out on the patients and on controls. The observations on the four women patients indicate a tissue sensitivity to extravasated red blood cells. The factor responsible was present in the red cell stroma and was not associated with the hemoglobin. All patients had had an episode of trauma associated with bruising before the onset of the painful ecchymotic lesions. The authors believe that the term "erythrocyte autosensitization" can be used to describe what has occurred here. They suggest that this syndrome may represent another example of autosensitization such as has been suggested for lupus erythematosus, some forms of acquired hemolytic anemia and of thrombocytopenic purpura, and for an increasing number of disease states.

The Mechanics of the "L. E." Cell Phenomenon, Studied with a Simplified Test. I. Snapper and D. J. Nathan. Blood 10:718-729 (July) 1955 [New York].

The discovery of the L. E. cell in heparinized bone marrow preparations of patients with disseminated lupus erythematosus by Hargraves and associates has been repeatedly confirmed. The L. E. cell consists of a neutrophilic polymorphonuclear leukocyte whose nucleus is compressed to the periphery of the cell by the cytoplasmic inclusion of a relatively homogeneous, swollen mass, which takes a pale blue color with Wright or Giemsa stains. All the current methods of detecting the L. E. cell involve the necessity for venipuncture, repeated and bothersome centrifuging, and the talents of a trained technician. The preparation of the smears in which the L. E. cells must be searched for requires hours of work. In some instances, when the diagnosis of disseminated lupus erythematosus is certain on clinical grounds, one may spend several fruitless hours searching for the L. E. cell. For these reasons an extremely simple, inexpensive, and rewarding method using one drop of finger blood has been devised by the authors. With this technique large numbers of lupus cells are formed by positioning one drop of finger blood or ear blood of a lupus patient upon an accumulation of dried, normal polynuclear leukocytes. Thick leukemic smears and perhaps even imprints of various carcinomas or Hodgkin's tissue can also be used as substrates. No false positive results were obtained in a group of control patients. Striking results were obtained with this method in 20 of 21 patients known to have disseminated lupus erythematosus. The remaining patient in whom a single L. E. cell was found by a conventional method to date has yielded no lupus cells by this method. The difference in appearance of the inclusion body of some of these cells from the characteristic Hargraves cell is highlighted. Theoretical considerations of the mechanism of lupus cell formation are discussed and reassessed in the light of the experience with this method. For the formation of L. E. cells it seems necessary that living polynuclear leukocytes, dead cells, and lupus serum be brought together. The lupus serum can depolymerize the desoxyibose nucleic acid of the nuclei of the dead cells but not of living cells. The depolymerized material is then phagocytized by living polynuclear cells and formation of lupus cells results.

The Inheritance of Porphyria. G. Dean and H. D. Barnes. Brit. M. J. 2:89-94 (July 9) 1955 [London, England].

The porphyrias are disorders involving profound disturbances in the metabolism of pyrrole pigments resulting at times in marked increase in the excretion of porphyrins in the urine. The authors investigated porphyria among Europeans in South Africa. The genealogies of 13 porphyric families, all of old stock and almost certainly related far back in South African history, have been traced and a number of other families await investigation. A total of 236 members (121 male and 115 female) had clinical manifestations of porphyria. The family tree of a large porphyric family group is presented. This group is typical of the 12 others that have been investigated. In all these groups porphyria has appeared in its acute form, in its chronic cutaneous form (the "cutanea tarda" type), or as a symptomless porphyrinuria. In many cases one type changed into the other. They are different manifestations of the same inherited disorder. Fifty per cent of the children of a porphyric parent will inherit porphyria and the distribution of the inheritance between the sexes is approximately equal. Porphyria, as it occurs in South Africa, is inherited as a Mendelian dominant characteristic and is not sex-linked. Cutaneous manifestations are more pronounced in men, acute attacks are more common in women. Men are more constantly exposed to the sun and to trauma; women appear more likely to be given sedative drugs or to be operated on for abdominal pain, often under a barbiturate anesthetic. Barbiturates may precipitate an acute attack of porphyria. There may also be endocrine factors. In the latent stage diagnosis may be difficult. The personal and family history is of the utmost importance, and the urine and feces should be examined by a biochemist who is experienced in detecting porphyrins. When a diagnosis of porphyria is made, it is important to trace the genealogical tree and to investigate the other members of the family group. These investigations will usually result in the discovery of many other cases in members of the family group, who could then be warned of the inherent danger.

Carcinoma of the Cecum: Clinical Analysis of 33 Cases. R. C. Lynch, S. B. Hutton and G. D. Johnson. Am. J. Gastroenterol. 24:53-60 (July) 1955 [New York].

During the 10 year period ending Dec. 31, 1952, of 125,000 new patients admitted to the Ochsner Clinic for examination there were 33 with proved carcinoma of the cecum. The authors analyze observations on these 33 patients in an attempt to elucidate early diagnostic features. Fourteen of the patients came to the physician because of pain. Eight patients had noted a definite change in bowel habits, and two complained of passage of blood from the lower bowel. In the remaining nine patients, a group of symptoms, including the presence of an abdominal mass, was the reason for medical consultation. Operation was performed on 32 of the 33 patients. The remaining patient was admitted to the hospital in extremis from intestinal obstruction. Four of the 32 patients operated on died in the hospital. Of the 28 patients who survived surgical treatment, 27 reported for subsequent examination. Of the two patients on whom exploration and biopsy were carried out, one died in the hospital and the other survived for one year. This patient had received several courses of nitrogen mustard therapy. Only one of the five patients on whom palliative ileotransverse colostomy was performed survived a comparable period. In 25 patients resection of the right colon and terminal ileum and ileotransverse colostomy was performed. One of these died shortly after operation, and it has been impossible to trace another. Of the remaining 23 patients, 7 died of recurrent metastasis within 14 months following operation. The remaining 16 are well or without evidence of metastasis for varying periods. From this group of cases it appears that carcinoma of the cecum develops in males at an earlier age than in females. The large number of patients reporting for examination with a long history of abdominal pain and secondary evidence of loss of weight and anemia underscores the necessity of complete examination, repeated, if need be, in individuals that are apt to be considered as psychoneurotic. Once again, the great difference in prognosis following operation for early or fully resectable carcinoma and for advanced lesions is apparent. This recurrent plea for early diagnosis should include advocation of abdominal exploration if there are definite indications of carcinoma without demonstrable roentgenographic evidence.

Experiences with Cortisone Therapy in Virus Hepatitis. L. Heilmeyer, F. Schmid and H. A. Kühn. Deutsche med. Wchnschr. 80:992-999 (July 1) 1955 (In German) [Stuttgart, Germany].

Heilmeyer and associates report on their experience with cortisone and corticotropin therapy in 50 patients (24 men and 26 women) with acute virus hepatitis. The ages ranged between 19 and 68 years. Only relatively serious cases were treated with cortisone, that is, those patients whose serum bilirubin content was above 10% at the time of their admittance to the clinic. In the majority of patients it was much higher, ranging up to 45%, the average being 17.2%. Treatment was usually begun about eight days after the onset of jaundice. The 50 patients of the control group were of about the same age range, and their average bilirubin values were 18.4%. All patients were kept in bed and received a diet of high carbohydrate and low fat content. Heat was applied locally and vitamin B complex and vitamin C, glucose, and levulose were given. In addition to these measures, the group treated with cortisone was given cortisone by mouth, beginning with 150 to 250 mg. per day, then 100 mg. daily for 8 or 10 days, until the patient received a total dose of 1,500 mg. On the last two days of cortisone therapy, corticotropin was given in addition, at first 20, then 30, then 50 units, and after that 30 or 20 units daily, for six days. Some of the patients in coma were given in addition continuous drip infusion containing levulose, total adrenal cortical extract, methionine, and choline. Liver function tests were made at regular (usually eight day) intervals. A surprising improvement in the general condition was the first noticeable effect of the cortisone treatment. Nausea and vomiting usually disappeared on the first or second day, also the asthenia. The appetite and food intake improved. Rapid decrease in serum bilirubin level was the most noteworthy sign of objective improvement. A return to values of 1.5 or 1 mg. of bilirubin in 100 cc. of serum was accomplished in about 56 days in the patients treated with cortisone and in 69 days in the control cases. This difference of 13 days is statistically significant. The other functional tests of the liver, particularly those that are specific for the liver cell, responded much less rapidly, such as the serum iron content and the prothrombin concentration. Death resulted in four patients who were comatose at the time of hospitalization and in four others in whom coma developed during cortisone therapy. One comatose patient responded to the combination of cortisone and the intravenous drip infusion with levulose, total adrenal cortical extract, choline, and methionine.

Laboratory Findings in Epidemic Hemorrhagic Fever. R. W. Speers, S. Katz, T. V. Parran and A. Steer. J. Lab. & Clin. Med. 46:28-40 (July) 1955 [St. Louis].

In 1951, physicians in Korea encountered a disease previously unknown to them, epidemic hemorrhagic fever. The authors report hematological, urinary, and blood chemistry findings in a group of 76 patients. In order to study the prognostic value of this laboratory information, a comparison is made between data from the group of 76, all but 6 of whom survived, and data from a group of 22 patients who died (6 fatalities of the original 76 plus 16 others). The 92 patients had epidemic hemorrhagic fever during an outbreak of the disease between April and July, 1952. Leukocytosis and a leukemoid response occurred in the peripheral blood during the acute febrile phase, and, soon thereafter, a lymphocytic response with the appearance of many atypical lymphoid cells was noted. A decreased number of peripheral blood platelets was observed during the hemorrhagic phase. Proteinuria, microscopic hematuria, granular celluria, oliguria, and azotemia appeared during the first week of illness, and renal concentrating function decreased. During the hypotensive or shock phase hemoconcentration was evidenced by abnormally increased blood hemoglobin and hematocrit values. The onset of diuresis during the second week of illness was usually associated with the onset of convalescence, during which abnormal findings returned to normal. In general, the white blood cell count, erythrocyte sedimentation rate, and renal concentrating function were last to return to normal. Abnormal laboratory findings in patients who subsequently died were of the same type as findings in patients who survived. Abnormalities of greater severity and more prolonged duration, however, occurred more commonly in fatal cases.

Serologic Investigations of Herpes Simplex Virus Infections. H. E. Dascomb, C. V. Adair and N. Rogers. J. Lab. & Clin. Med. 46:1-11 (July) 1955 [St. Louis].

The virus of herpes simplex has been related etiologically to such clinical syndromes as Kaposi's vericelliform eruption, fulminating visceral disease with hepatitis, stomatitis, and fatal or near-fatal encephalitis. Recent investigations have shown that herpes simplex virus may be implicated etiologically in aseptic meningitis about as frequently as mumps or lymphocytic choriomeningitis virus or the leptospiras. This report is concerned with an evaluation of the complement fixation test, which is a simple and rapid procedure for serologic investigations and which may supplement or be a substitute for the more laborious neutralization test. A complement-fixing antigen was employed in which the infectivity was destroyed by exposure to ultraviolet light. The patients selected for study were United States military personnel or their dependents who were treated at a dispensary or hospital for herpetic or nonherpetic disease. Specimens for isolation of virus consisted of fragments of tissue, or body fluids, or swabs of exudate collected from patients during the course of their disease or at autopsy of fatal cases. Attempts to recover the virus in animals or embryonated eggs were performed using specimens freshly collected or stored frozen at -70 C (-94 F) for a few days prior to inoculation. Blood samples were obtained from the patients during the acute phase of their illness and again at variable periods during convalescence. A complement fixation test for herpes simplex employing irradiated noninfectious antigen of chick embryo origin provides a simple, rapid procedure for the specific assay of antibody against herpes simplex virus. The results of the complement fixation test correlate well in the majority of instances with those of the in ovo neutralization test. However, the two procedures presumably measure different antibodies. In certain patients, namely, those with primary superficial mild herpes simplex, neutralizing antibodies appear without associated complement fixation antibodies. Both types of antibodies develop in patients with severe primary herpes. In the recurrent type of disease both types are usually present in the earliest available sample of serum, but in a fair proportion of patients one or the other antibody may increase in titer during convalescence. The complement fixation technique is a valuable diagnostic tool in many types of herpetic infection, especially those involving the central nervous system, but it does not replace the neutralization test or the viral isolation and identification procedure. Studies on the distribution of complement fixation antibodies against herpes in normal population groups of different ages provided data in general accord with the older observations of distribution of neutralizing antibodies. In general, the occurrence of complement fixation antibodies is infrequent in children and young adults, but the majority of persons over 30 have these immune substances. The complement fixation method is useful in serologic surveys designed to detect past infection with herpes simplex.

Aspirin and Ulcer. A. Muir and I. A. Cossar. Brit. M. J. 2:7-12 (July 2) 1955 [London, England].

In 1947 Muir and Cossar started experimental and clinical investigations on the possible harmful effects of aspirin on the stomach, particularly in patients with peptic ulcer. In 20 patients with radiologically confirmed peptic ulceration, three standard caffeine-citrate fractional test meal examinations were performed at intervals of a few days. The first test served as a control. After the removal of the fasting juice during the second and third meals, two bland calcium lactate tablets and two 5 grain (0.32 gm.) aspirin tablets were given, respectively, uncrushed, with a little water. In five patients blood-staining of the specimens was observed during the aspirin test meal alone. In one case it was much greater than had been observed during the calcium lactate test meal; in two it was similar; and in one it was less. The conversion by aspirin of a previously consistently negative test for fecal occult blood to a strongly positive one in three patients also seemed significant. In order to obtain pathological proof of the effect of aspirin on the stomach, two uncrushed 5 grain (0.32 gm.) aspirin tablets were given with a little water to patients two hours prior to gastrectomy for peptic ulceration. Of 20 patients who received ordinary commercial brand aspirin, 12 had macroscopic evidence of mucosal irritation in the form of an acute gastritis. The lesion was always most marked in the pyloric antrum and on the lesser curvature. The picture was typical of an acute erosive gastritis. Of the 20 patients who received specially hard aspirin tablets, only 8 showed acute erosive gastritis, and no severe lesions were seen in this series. These findings were unexpected in view of the frequency with which large portions of residual aspirin were found in the stomach. It was anticipated, as a result of the findings in the first series, that this would increase the more severe type of lesion. However, in almost all cases the residual aspirin was coated in a thick capsule of dense mucus. Of the 20 patients who received soluble aspirin, 18 showed no mucosal reaction. As a preliminary investigation to clinical studies, 300 persons were questioned about aspirin intolerance. About 1 in 20 admitted that aspirin gave them dyspepsia—heartburn, sometimes nausea, and occasionally epigastric discomfort. Then 318 patients with peptic ulcer were questioned, and approximately one-third (110) knew that aspirin could be taken only at the risk of dyspepsia. Some felt that ulcer pain could be aggravated or restarted by taking aspirin. A group of 83 peptic ulcer patients, who had periodic bouts of ulcer pain with long remissions, were questioned to ascertain the factors causing their latest recurrence. Fourteen of 34 gastric ulcer patients and 19 of 49 duodenal ulcer patients admitted to taking aspirin less than 24 hours before the recurrence of their symptoms. The fact that 15 patients with severe dyspepsia who were habitual aspirin takers were cured of their dyspepsia by its withdrawal proves that dyspepsia may be caused by aspirin. Questioning of patients with hematemesis revealed a large number who had taken aspirin within a few hours of their hematemesis. Even if the 11 patients of this series who took aspirin regularly are eliminated, there still remain 43 patients among 166 in whom aspirin seemed at least a precipitating factor of hematemesis. However, only 1 of 31 patients admitted taking aspirin within six hours of acute duodenal perforation. Aspirin should never be given to patients with peptic ulceration or to those who have any gastric intolerance for it. This instruction should be given a prominent place in peptic ulcer advice charts.

So-Called Late Chlorosis with Dysphagia. R. J. H. Kruisinga. Nederl. tijdschr. geneesk. 99:1907-1911 (June 25) 1955 (In Dutch) [Haarlem, Netherlands].

The author believes that the clinical picture under consideration in this paper should not be designated as the Plummer-Vinson syndrome (dysphagia with glossitis, anemia, splenomegaly, and atrophy in the mouth, pharynx, and esophagus), because the description given by these authors is not quite correct, and they were not the first to describe it. The term late chlorosis with dysphagia likewise is not quite suitable, because the anemia does not have the importance attributed to it. Besides the disturbance in swallowing, which was the starting point of the investigation by the present author, the following symptoms may be present: atrophy of the mucosa of the tongue and of the pharyngeal wall, a small mouth, perlèche (desquamation at the labial commissures), falling out of the hair, brittle nails, leukorrhea, gastric achylia refractory to histamine, iron deficiency, and anemia. For a period of one year the author watched for the disorder in question among the new admissions to his outpatient department. All patients who showed signs of the syndrome complained of difficulties in swallowing. After excluding all who did not have a minimum of seven positive signs, there remained nine patients, all women. A table shows the presence or absence of the various symptoms in these nine women. The average width of the mouth in 94 normal women was 11 cm., and in the 9 women with the syndrome in question it ranged from 8 to 9.75 cm. Brittle nails and falling out of the hair were absent in only one patient each; and smooth tongue and perlèche were lacking in two patients each. Changes in the pharyngeal mucosa were absent in three patients, roentgenologic changes in the pharynx in four patients, and esophagoscopic changes in five patients. Anemia and iron deficiency were each found in only two of the nine patients. Studies failed to reveal any endocrinologic disturbances.

Hyperchlorhydria—Can It Be Controlled Medically? E. Boros. Am. J. Gastroenterol. 24:61-68 (July) 1955 [New York].

Hyperacidity frequently resists medical control. The studies described were pursued for the purpose of ascertaining the degree of neutralization possible by the administration of food and alkali. In patients with digestive complaints accompanied by hyperchlorhydria, the fasting gastric contents are obtained on the morning of examination. Immediately thereafter, four ounces of milk is drunk. The patient is intubated in one half hour and one teaspoonful of calcium carbonate is given with a small amount of water. One half hour later, the contents are again withdrawn. This routine is carried out over a three hour period, making a total of seven gastric specimens. A day or so later, the same patients were again intubated. After the withdrawal of the fasting secretion, a meat sandwich with some water was consumed. Thereafter, at one half hour intervals, calcium carbonate in one teaspoonful doses was administered as previously, and prior to each of these doses the gastric contents were withdrawn. A feature of these tests was the use of the Levin tube, which was introduced through the nostril. Tests were made on 20 patients with duodenal ulcer and on 21 with evidence of gastritis or functional disorders, but without a history or signs of peptic ulcer. The fasting contents in most of the ulcer patients were elevated above normal standards. In only 3 of this group of 20 was there a total and complete neutralization of free acid in all of the specimens extracted. The remainder showed varying degrees of hydrochloric acid in one or all of the specimens. Hyperacidity in the nonulcer cases appeared to yield more rapidly to antacids. As an informative test of gastric secretory response, the routine use of alternating milk and calcium carbonate as described offers better prospects of a diagnostic aid and possible therapeutic guide than the solitary Ewald meal extraction or the Rehfuss method of gastric study. The role that hydrochloric acid has assumed in gastric disease requires further clarification.

Cortisone Test in Hyperfunction of Adrenal Cortex. V. Gilsanz, J. M. Segovia and J. Linazasoro. Rev. clín. españ. 58:17-20 (April 15) 1955 (In Spanish) [Madrid, Spain].

The cortisone test is useful in differentiating adrenal hyperplasia from adrenal neoplasm as cause of the syndrome of adrenal hyperfunction. Evaluation of the results is made from the concentration of urinary 17-ketosteroids before and after the test. A dose of 100 mg. of cortisone is given intramuscularly at intervals of 12 hours for five days. According to reports in the literature, a significant fall in urinary 17-ketosteroids during the test indicates adrenal hyperplasia, whereas the lack of diminution of urinary 17-ketosteroids indicates adrenal neoplasm as cause of the syndrome of adrenal hyperfunction. The authors performed the test in three patients. One patient was a boy 9 years old with macrogenitosomia praecox caused by a large adrenal carcinoma. Two patients were adults with adrenal cortical hyperfunction due to adrenal hyperplasia. The adrenal carcinoma and hyperplasic adrenal glands, one in each patient, were surgically removed and examined. The urinary 17-ketosteroids greatly diminished in the course of the test in the patient with adrenal carcinoma, whereas they did not diminish or diminished but very little in the patients with adrenal hyperplasia. The results diminish the value of the cortisone test for the differential diagnosis between neoplasm or hyperplasia as cause of the syndrome of adrenal hyperfunction.

SURGERY

The Selection of Patients with Mitral Stenosis for Valvular Surgery. L. B. Ellis. Am. Pract. & Digest Treat. 6:1149-1155 (Aug.) 1955 [Philadelphia].

The classification of patients with mitral stenosis in four groups as developed by Ellis follows as far as possible the classification of the New York Heart Association, except that the author's classification, instead of describing the momentary condition of the patient at the time of observation, takes into account the course and progression of the disease. Group 1 includes patients without significant symptoms who may go many years without any disability and, therefore, should not be operated on. Patients in group 2 have some symptoms that are not progressive and do not interfere seriously with their productive activities; although operation can be postponed in these patients, those who will not accept the handicap of their disability may be subjected to mitral valvuloplasty with insignificant operative risk. Patients in group 3 are those in whom operation is urgently indicated. These are patients with progressive disability, chiefly pulmonary, consisting of increasing chronic dyspnea or attacks of acute dyspnea or other pulmonary symptoms. Gross hemoptysis may occur and is of serious import. Chronic congestive symptoms of any magnitude have not developed in these patients, most of whom still do light housework or carry on a sedentary occupation, but only with difficulty. Results of valvulotomy are most gratifying in this group and the operative risk is low. Group 4 consists of the patients with a more advanced cardiac breakdown, mostly chronic or recurrent congestive failure. Although many workers felt that such patients are inoperable, the author has always accepted them for operation and the results have often been surprisingly good, but not so striking as in group 3. The operative risk remains high (about 20%). Special features that affect the operative risk, such as mitral insufficiency, auricular fibrillation, calcification of the mitral valve, associated disease of the aortic valve, tricuspid stenosis, active rheumatic fever, associated disease of any type, and peripheral embolization, are discussed. There is no absolute age limit for the operation. Mitral valvulotomy confers a genuine and usually lasting benefit on properly selected patients with mitral stenosis. Proper selection is primarily the responsibility of the attending physician. The patient should be suffering from symptoms truly caused by the altered hemodynamics secondary to the mitral stenosis. It is important to exclude symptoms of functional nature, anxiety neurosis, or neurocirculatory asthenia. Cardiac catheterization may be helpful in evaluating patients of this type if a decision cannot be reached on clinical grounds. Mitral valvuloplasty is not a proper treatment for patients with predominantly functional symptoms and rarely confers any lasting benefit on them. In patients with mitral stenosis, mitral valvuloplasty has a useful place in their treatment, but is a palliative procedure, frequently a lifesaving palliation, not a cure. The valve function may be considerably improved, but the valves are not returned to normal. Patients who have had mitral valvuloplasty, even if they are rendered symptom-free, are still cardiac patients and should be under medical supervision the rest of their lives.

Surgical Management of Lesions of the Thoracic Duct: The Technic and Indications for Retroperitoneal Anastomosis of the Thoracic Duct to the Hemiazygos Vein. L. A. Brewer III. Am. J. Surg. 90:210-227 (Aug.) 1955 [New York].

Brewer's studies revealed that subdiaphragmatic thoracic duct fistulas are not uncommon and may be responsible for leakage of chyle up into the chest or down into the femoral region of the thigh. On the basis of study of 8 personal cases and a review of hospital records on 16 others, a definite plan of treatment for each region has been made. In this series chyle most often formed in the abdominal and combined abdominothoracic regions; next often in the thoracic region alone, and rarely in the neck and femoral region of the thigh. Trauma and malignant tumor proved to be the most common causes of chylous extravasation, although the number of undiagnosed conditions was large. The location of the fistula of the thoracic duct is as important as the cause in determining the treatment. In the cervical and thoracic regions, simple ligation of the duct is generally successful. Below the diaphragm the treatment of chylous fistulas has been generally neglected. The author gives particular attention to the management of abdominal accumulations of chyle. He discusses the indications for the anastomosis of the afferent thoracic duct (and efferent, at times) to the hemiazygos or azygos veins, and he describes his original technique of this retroperitoneal anastomosis of the thoracic duct to the hemiazygos vein. Aspiration of chyle and/or deep x-ray therapy resulted in a high mortality, while ligation and anastomosis procedures have a low mortality (none in the author's series) and a high rate of cure. The author feels that the extension of surgical treatment to lesions below the diaphragm, as outlined by him, should reduce the mortality and improve the rate of permanent cure.

The Significance of Axillary Node Levels in the Study of Breast Carcinoma. J. W. Berg. Cancer 8:776-778 (July-Aug.) 1955 [Philadelphia].

Histological examination of the axillary lymph nodes removed from patients undergoing radical mastectomy shows that metastasis usually progresses by levels corresponding to the locations of the nodes along the theoretical path of axillary lymphatic drainage from the breast to the mediastinum. Level 1 includes nodes lateral and inferior to the pectoralis minor muscle; level 2 includes those behind it; and level 3 includes the few that are medial and superior to it. The material studied was obtained from the records of operable breast carcinomas treated at Memorial Center for Cancer and Allied Diseases, New York, in 1950—the earliest year in which essentially complete histological studies of axillary nodes were made. The 324 cases finally selected all met the following criteria: (1) the primary cancer had been measured; (2) the axillary nodes had been separated into the three standard levels; (3) the described gross involvement of any level was proved microscopically; (4) all nodes were embedded and examined microscopically at any and every level where gross metastases were not recognized; and (5) a three year follow-up was available and the patient was either living or dead of disease. The material was then grouped by primary size and level of axillary involvement (verified in every case by reexamination of the microscopic sections), and the statistical significance of the resulting distributions was determined by the chi-square test. No statistically significant differences were found in the three year mortality rate between tumors of any given size with no positive nodes and those of the same size in which only the nodes in level 1 were positive. The presence of metastases at level 3, however, in carcinomas of equal size was accompanied by a three year mortality rate five times as high as when the axillary nodes were negative. Level 2, with a three year mortality rate twice that of level 1 and half that of level 3, was apparently a true intermediate. The level of axillary node involvement thus seems to be more closely related to the prognosis of a given case than the size of the primary lesion, but both factors must be considered if an accurate evaluation is to be obtained. Carcinomas with level 2 metastases, for instance, had an over-all three year mortality rate of 26%, but, when the primary cancer was less than 4 cm. in diameter, the mortality was only 17%, while for cancers 4 cm. and over in diameter the mortality rate rose to 47%. The comparable figures for primary cancers less than 3 cm. in diameter were 20% for the over-all three year mortality; 7%, if level 1 only was involved, or substantially the same as the 6% rate found when all nodes were clear; and 56% when the level 3 nodes showed metastases. The pattern of metastatic progression shown by these studies can be used in most cases as a guide in evaluating the possible extension of cancer beyond the limits of the operative field. The fact that 11 patients without axillary node metastases had died of their disease within three years shows that there are other channels of extension for breast cancer besides the main axillary pathway.

Clinical Evaluation of Bilateral Adrenalectomy and Oophorectomy for Advanced Mammary Carcinoma. M. Galante and H. J. McCorkle. Am. J. Surg. **90**:180-188 (Aug.) 1955 [New York].

Bilateral adrenalectomy and oophorectomy was performed in 50 patients. Only patients with objectively demonstrated breast cancer that had advanced beyond the possibility of further surgical or radiation treatment were selected. Usually some form of hormone therapy had been tried. Most of these patients had widespread disease, usually in one or more of the following locations: bones; pulmonary, pleural, or abdominal viscera; lymphatics; and/or local recurrence in the chest wall. The operations frequently were performed on patients confined to bed with debility and pain. Two patients died postoperatively. One of these was jaundiced and had extensive liver metastases; the other was debilitated. With one exception patients with jaundice or extensive liver metastases did poorly, and it is now apparent that the procedure is contraindicated in the presence of either. The follow-up period varied from 1 to 34 months. Twenty-one patients died from 1 to 18 months after the operation. Eighteen patients showed objective improvement; 28 improved subjectively; and 15 failed to show any favorable effect. The longest period of improvement was 28 months. The reduction in size of tumor mass, the healing of ulcerations, the roentgenologic evidence of recalcification of an osteolytic lesion, and the disappearance of pleural effusions and abdominal ascites were interpreted as evidence of improvement. Improvement was most dramatic in bedridden patients with widespread osseous metastases. Cessation of pain usually occurred immediately following operation or within the first 24 hours. Paradoxically this also occurred in the presence of objective evidence of progression of the lesions. Substitution therapy is an important part in the management of adrenalectomized patients.

New Physiologic Concepts Related to the Surgical Treatment of Duodenal Ulcer by Vagotomy and Gastroenterostomy. H. A. Oberhelman Jr. and L. R. Dragstedt. Surg., Gynec. & Obst. **101**:194-200 (Aug.) 1955 [Chicago].

Oberhelman and Dragstedt found that failures in the treatment of duodenal ulcer by vagotomy and gastroenterostomy usually occurred in patients with incomplete division of the vagus nerves or in those in whom there was persistent stasis of food in the stomach. Attention was previously directly to the necessity of dividing all, or nearly all, of the vagus nerves to the stomach in order to abolish the nervous phase of gastric secretion. It is the purpose of the present communication to emphasize the importance of an efficiently functioning drainage procedure whenever gastric vagotomy is performed. It has been demonstrated in animals that complete gastric vagotomy may produce a prolongation of the antrum or humoral phase of gastric secretion because of stasis of food in the stomach. A high-lying gastroenterostomy produces stimulation of gastric secretion in experimental animals, but this does not occur if the gastroenterostomy stoma is located in the antrum near the pylorus. Analysis of failures in the treatment of duodenal ulcer by vagotomy alone and by vagotomy combined with gastroenterostomy disclosed that stasis of food in the stomach and a high-lying gastroenterostomy were important factors in many patients. Experimental and clinical evidence presented indicates that the stoma should be placed in the antrum within 4 or 5 cm. of the pylorus whenever a gastroenterostomy is done along with vagotomy in the surgical treatment of duodenal ulcer.

Cushing's Disease: The Surgical Experience in the Care of 46 Cases. O. Cope and J. W. Raker. New England J. Med. **253**: 119-127 (July 28) and 165-172 (Aug. 4) 1955 [Boston].

Since 1935, 46 patients with adrenal cortical hyperfunction (Cushing's disease) have been cared for at the Massachusetts General Hospital. Suppression of the action of the anterior pituitary gland either by roentgen ray irradiation or by the administration of testosterone has proved successful in two patients only. Surgical treatment has emerged as the consistently practical therapy. The disease is one of overactivity of the adrenal cortex, much as Grave's disease manifests itself by overactivity of the thyroid gland. The anterior pituitary gland appears to bear much the same relation to both diseases. When adrenal cortical hyperfunction is caused by a tumor of the adrenal gland, the problem is one of complete removal of the tumor, leaving the contralateral uninvolved gland. A neoplasm was found in 17 of the other 44 patients. In five it was malignant and all of these died of metastatic disease. The other 12 had benign neoplasms. One died before surgical treatment was carried out; 11 survived the operation and were cured by resection. Twenty-seven patients with bilateral adrenal hyperplasia were treated by subtotal resection. To achieve a consistent therapeutic result in patients with adrenal hyperplasia, it has been found necessary to remove at least 90% of the adrenocortical tissue. In two patients the hyperplasia was associated with multiple nodules, a phase of the adrenal change believed comparable to nodular goiter with hyperthyroidism. Of the 27 patients, 2 died before the surgical intervention; of the 4 patients who underwent limited resection, 2 died of active disease and 2 are living with residual disease; 2 others died after surgical relief of the disease; 19 are living and cured. Cortisone administration facilitated an adequate surgical attack, particularly in patients with hyperplasia of the adrenal cortices. In addition to the use of cortisone to offset acute cortical insufficiency, management of the postoperative phase requires an understanding of an acid nutritional need as healing occurs. There is as yet no medical treatment of adrenal cortical hyperfunction comparable to that of hyperthyroidism with antithyroid drugs or radioactive iodine.

Conversion of Billroth II to Billroth I for the Relief of Postgastrectomy Symptoms. C. Mathewson Jr. Am. J. Surg. **90**: 317-324 (Aug.) 1955 [New York].

Most surgeons agree that postgastrectomy symptoms are less severe and of shorter duration after a gastroduodenal anastomosis of the Billroth I type than after a gastrojejunal anastomosis of Billroth II type, but the Billroth I type of gastroduodenostomy has been limited mostly to patients with gastric ulcer and to those with proximal duodenal ulcer without fixation and with a mobile duodenum. Gastrojejunostomy has become the procedure of choice with many surgeons, because it does not limit the amount of stomach that can be resected and continuity can always be established safely. A number of modifications of the original Billroth I type of gastroduodenal anastomosis have been advocated mainly to accomplish gastroduodenal anastomosis at the time of the original gastric resection, but in recent years it has been advocated as a conversion procedure after gastrojejunal anastomosis has been accomplished and has failed. The author presents the histories of two patients in whom he resorted to this conversion of a Billroth II to a Billroth I procedure. The first patient had a bleeding duodenal ulcer, not relieved by two years of medical treatment, that was subjected to an inadequate gastric resection of the Billroth II type. Soon after operation symptoms of recurrent ulcer developed that later caused severe gastrointestinal hemorrhage. Following resection of the marginal ulcer and an adequate gastric resection, gastrointestinal continuity was reestablished by gastroduodenal anastomosis. Postprandial epigastric distress occurred in the immediate postoperative period, requiring frequent small feedings, but the patient gained weight and strength, was relieved of pain, and, after six months, became asymptomatic. When last seen 22 months after the last operation he was well. In the second patient epigastric pain, vomiting, and severe loss of weight developed shortly after gastrectomy of the Billroth II type and were not relieved by medical treatment, cholecystectomy, revision of the Billroth II type of gastric resection with shortening of the afferent jejunal loop, or vagotomy. Conversion of the gastrojejunostomy to a gastroduodenostomy with interposition of a segment of jejunum resulted in immediate relief of pain and vomiting and initiated a prompt and pronounced gain in weight. Neither of these two patients has been watched long enough to eliminate the possibility of recurrent duodenal or jejunal ulcer. Nevertheless, the dramatic relief of symptoms together with the rapid gain in weight and strength, particularly in the second patient, makes this procedure one well worth consideration for the relief of serious postgastrectomy symptoms.

Experiences with 1,356 Cases of Cholecystitis and Cholelithiasis. B. P. Colcock and J. E. McManus. Surg., Gynec. & Obst. **101:** 161-172 (Aug.) 1955 [Chicago].

Colcock and McManus review the clinical records of 1,356 patients operated on at the Lahey Clinic in Boston for disease of the biliary tract over the four years from 1950 to 1953 inclusive. These may be compared in many details with an earlier group of 1,104 patients reported from this clinic in 1947. The authors feel that all but a few patients with biliary calculi will have some symptoms of their disease. A careful history and the use of the cholecystogram provide accurate means of making the diagnosis in these patients. An increasing number of patients over 60 years of age are being operated on for cholelithiasis. Acute cholecystitis and common duct stones, the major complications of cholelithiasis, occur more frequently in patients over 60, and they frequently coexist. A definitive operation for patients with cholelithiasis can be done only by an accurate demonstration of the cystic duct and its junction with the common duct. Careful exposure of the common duct is necessary to evaluate the need for choledochostomy and should result in fewer rather than more common duct injuries. The authors feel that the number of patients who have had an injury to the common bile duct during the course of a cholecystectomy forms an unsightly blot on the record of modern surgery. Over 500 of these unfortunate individuals have been sent to their clinic because of this complication, and many of these patients ultimately will die as a result of cholcystectomy. The mortality in the authors' group of patients was 1.1%. The principal factors responsible for the deaths were the relatively large number of patients over 60 years of age, extensive disease of the biliary tract as indicated by the presence of jaundice, and the number of patients requiring secondary operations upon the biliary tract. If, in most instances, patients with cholelithiasis were advised to have a cholecystectomy (with choledochostomy when indicated) when their stones are discovered, before complications have developed and before they enter the older age groups, the mortality and the morbidity of biliary tract disease would be improved. The authors feel that surgeons should periodically review their experiences with surgery of the biliary tract, to know the operative mortality, the incidence of complications, and the number of, and reasons for, unsatisfactory results following cholecystectomy.

Feasibility of Partial Hepatic Resection Under Hypothermia. W. F. Bernhard, J. D. McMurrey and G. W. Curtis. New England J. Med. 253:159-164 (Aug. 4) 1955 [Boston].

The effect of cooling on the liver parenchyma alone, and the effect of one hour of ischemia on that organ resulting from afferent hepatic vascular occlusion were studied in dogs in which hypothermia was induced by means of an ice-water bath. Normothermic dogs in which temporary hepatic ischemia was produced by afferent hepatic vascular occlusion and dogs in which hypothermia but no afferent hepatic vascular occlusion was produced, served as controls. Microscopic study of the liver of hypothermic animals with and without afferent hepatic vascular occlusion did not reveal marked alteration in liver architecture except congestion and no residual damage as determined by routine techniques. Dogs subjected to hypothermia had negative results from liver function tests. All normothermic dogs with afferent hepatic vascular occlusion for one hour died, a mortality rate of 100%. Preoperative administration of antibiotics did not alter this result. With the aid of hypothermia, vascular occlusion of the hepatic afferent artery for one hour was carried out successfully, with only two deaths in 27 dogs. There were no deaths in the last 20 consecutive dogs experimented on. No antibiotics were administered. During the one hour period of hepatic ischemia in the dogs subjected to hypothermia, it was possible to perform extensive liver resections in a dry field. Individual suture ligations of empty vessels in portal triads were easily accomplished during the resection, and thus massive compression ligatures were largely unnecessary for hemostasis. It is suggested that the surgical indications for the use of hypothermia be extended to include patients with hepatocellular disease requiring anesthesia and surgical treatment, patients with primary or secondary tumors of the liver who might be successfully treated by resection of the liver, and patients with tumors invading the portal vein who might not otherwise be considered capable of surviving operation.

Isolated Lipodystrophy, a Form of Mesenteric Tumor. J. T. Crane, M. J. Aguilar and O. F. Grimes. Am. J. Surg. 90:169-179 (Aug.) 1955 [New York].

Proper management of mesenteric lesions depends on recognition of the differences between true neoplasms and certain nonneoplastic tumorous processes of the mesentery. These latter conditions include Whipple's disease (intestinal lipodystrophy), the systemic variant of Weber-Christian disease (systemic nodular panniculitis), sclerosing lipogranuloma, tuberculous mesenteric lymphadenitis, and traumatic and pancreatic fat necrosis. The authors observed five cases of mesenteric tumor that differed sufficiently from the foregoing to suggest a unique entity. The lesion was found in five adults, all of whom had either no or only slight symptoms relating to the lesion. In four an abdominal mass was palpable. Diagnosis was established at exploratory laparotomy in three patients, and at postmortem in the remaining two. Grossly, the entire small bowel mesentery was thickened and nodular, rubbery firm, opaque, and mottled grey to yellowish orange. Microscopically, there was diffuse involvement of fat cells, most prominent about the periphery of the fat lobules. In the early stages individual fat cells appeared smaller than normal; their cytoplasm was opaque, granular, and faintly basophilic, and the nucleus was centrally situated. Later, a mild focal lymphocytic infiltration and perilobular condensation of fibrous tissue were apparent. Lipogranulomas developed rarely. It is suggested that initial proliferation of mesenteric fat induces a permanent alteration in fat cell metabolism through either vascular or mechanical embarrassment. The fat cells, particularly those of the relatively more ischemic peripheral portions of the lobules, lose their ability to absorb fat and their lipolytic activity is compromised. These cells undergo the aforementioned structural changes; and, as the process progresses, they may break down, liberating fatty acids and exciting focal inflammation and fibrosis. These mesenteric masses bear certain resemblances to Whipple's disease, Weber-Christian disease with systemic involvement, sclerosing lipogranuloma, or traumatic or pancreatic fat necrosis. They must also be differentiated from true fat tumors, lymphosarcoma, tuberculosis, and other less common conditions. In the living patient diagnosis can be made only at operation. Biopsies should be taken not only of the mesentery but also of the bowel and mesenteric lymph nodes. Surgical resection usually is not feasible, as the process tends to surround the major mesenteric vessels. The prognosis apparently is favorable, for the lesion is slowly progressive and probably self-limited.

The Use of Streptococcal Enzymes in the Immediate Closure of Contaminated Incisions. S. W. Smith. Surg., Gynec. & Obst. **101**:173-184 (Aug.) 1955 [Chicago].

This study was undertaken to determine whether instillation of streptokinase and streptodornase into infected, grossly or potentially contaminated incisions would permit immediate closure of these wounds. The method was used in 73 patients divided among the following categories: ruptured appendixes, colon operations, draining sinuses, posterior wounds of abdominoperineal resections, infected amputation stumps, cholecystectomy incisions, secondary closure of infected incisions, and deep abscesses. Closure of an appendectomy incision was performed in the following manner: the peritoneum, muscle layers, and fascia were closed in the usual manner with running or interrupted chromic catgut. A polyethylene tube and small Penrose drain were laid in the subcutaneous fat overlying the fascia, and the subcutaneous tissue was approximated with fine chromic sutures. Skin closure was then done with silk sutures or clips, leaving a short aperture at the dependent or lateral end for drainage. In the earlier cases, a second polyethylene tube was introduced through the fascia layer down to the transversus fascia. Later it was found that the introduction of one tube into the fat was adequate to prevent infection. Contact for four to six hours between enzyme solution and the interstices of the closed incisions is of great importance, as is complete drainage of the solution and its lysed products after the contact. Instillation in concentrations of 10,000 units of streptokinase and 2,500 units of streptodornase per cubic milliliter was used once daily for periods of four to six hours. This treatment was continued for from 3 to 12 days, but an average of from 5 to 7 days was usually adequate. For the purpose of standardization of technique and reduction of variables, no antibiotic drugs were used with the enzymes in this study. It is likely that addition of the proper antibiotic agent would be of definite topical value and augment the parenteral effects. The use of streptokinase and streptodornase after closure of contaminated incisions favorably influenced the uncomplicated healing in most of the patients. Results have been uniformly favorable, and it is believed that the method constitutes a useful adjunct to careful operative technique and antibiotic therapy in achieving immediate closure of wounds that would usually be left open or secondarily closed. Since the liquefying and irritating properties of streptokinase and streptodornase aid in promoting drainage from closed wounds, improved drainage is possibly an important factor in achieving the results obtained in this study.

Arteriovenous Pulmonary Aneurysm in Osler's Disease (Hereditary Hemorrhagic Telangiectasia). G. Dienemann. München. med. Wchnschr. 97:818-820 (June 24) 1955 (In German) [Munich, Germany].

A man, aged 52, was hospitalized in 1954 because of pulmonary symptoms. Frequent attacks of epistaxis (nosebleed) and bluish-red spots in the face had first been noted in 1942. When in March, 1954, he was subjected to roentgen examinations, he complained of cough, headaches, dyspnea, and frequent attacks of epistaxis. Examination showed cyanosis of skin and mucous membranes, numerous reddish-blue areas of telangiectasia and small varicoid nodules on face, lips, ears, scalp, conjunctiva, palate, malar mucosa, tongue, uvula, and particularly on the nasal mucosa. Percussion revealed no differences in resonance, but vesicular breathing could be heard over both lungs; there were no adventitious sounds, not even after coughing. The patient had clubbed fingers and toes, and small areas of telangiectasia could be seen on the fingertips and under the nails. A survey roentgenogram of the thorax revealed streaks of increased density and some veiled opacity in the left lower lobe. The hilus appeared somewhat wider, and, at the edge of the heart near the anterior ends of the fourth to sixth ribs, there was a deep, sharply defined shadow, which seemed connected with the hilus by a streak. Tomography revealed a wide vascular band leading to the tumor; bronchography, however, revealed no signs of a tumor, and so there arose suspicion of an arteriovenous aneurysm. The kymographic examination revealed pulsation of the tumor. After angiography of the pulmonary artery, the existence of an arteriovenous aneurysm was no longer doubted. Operation revealed, however, that the aneurysm was not in the lower lobe but rather in the retrocardial lingula pulmonis, which is a projection of the upper lobe. Ligation of the dilated vessels and ectomy of the lingular segments was accomplished. Roentgenoscopy of the surgical specimen, which still contained contrast medium, disclosed a second aneurysm at the lowest point of the lingula. This one had never been seen during roentgenoscopy, because it was covered by the shadow of the diaphragm. The patient died seven days after operation from cerebral embolism. The author feels that arteriovenous pulmonary aneurysms should be resected. Regarding the concurrence of arteriovenous pulmonary aneurysm with the relatively rare hereditary hemorrhagic telangiectasia (Rendu-Osler-Weber disease), the author says that some or all of the symptoms of Osler's hereditary hemorrhagic telangiectasia have been found in over half of the 165 patients with arteriovenous pulmonary aneurysm reported in the world literature. It is possible that the concurrence of these two diseases is even more frequent, in that in some cases the symptoms of hereditary hemorrhagic telangiectasia may have been too slight to be recognized. It has been suggested that arteriovenous aneurysm of the lung might be one form of hereditary hemorrhagic telangiectasia. The author feels that arteriovenous pulmonary aneurysms should be searched for in all patients with hereditary hemorrhagic telangiectasia.

Hepatic Necrosis Following Celiac Artery Ligation During Gastric Resection in Man. J. S. Clarke. A. M. A. Arch. Surg. 71:171-177 (Aug.) 1955 [Chicago].

Two innovations in surgical therapy, one for cancer of the stomach and the other for portal hypertension, involve ligation of the main arterial blood supply to the liver. Appleby excised the celiac artery during en bloc resection for gastric carcinoma, and others ligated the hepatic, splenic, and left gastric arteries for advanced cirrhosis of the liver with bleeding esophageal varices. The author performed celiac artery ligation in two patients with noncirrhotic livers during gastrectomy for cancer of the stomach and gave penicillin afterward. Focal infarction was present in the livers at death, on the 8th and 24th postoperative days, respectively, but was not extensive enough to cause liver failure. The two cases are of special significance when considered in the light of recent experimental and clinical findings concerning the effect on the liver of ligation of the hepatic artery. A clear distinction must be made between (a) ligation of the celiac artery or of the hepatic artery near its origin, (b) ligation of the distal hepatic artery or its branches near their entrance into the liver, and (c) ligation of both the proximal hepatic artery and its branches or excision of the entire hepatic artery and its branches to the liver. The consensus of experimental and clinical evidence is that ligation of the proximal hepatic artery is innocuous and that ligation of the distal hepatic artery may, but does not always, cause liver necrosis in man. The two patients reported on had histological evidence of severe and rather extensive damage to a previously normal liver following celiac artery ligation with division of the common hepatic artery proximal to its gastroduodenal branch; this method preserved the superior mesenteric-inferior pancreaticoduodenal-superior pancreaticoduodenal-gastroduodenal-hepatic artery collateral route to the liver. The location of the infarcts far from the dome of the liver and the collateral inflow from the phrenic artery branches may thus indicate the pattern of arterial collaterals available to the liver after the celiac artery is ligated. Although the liver may survive hepatic artery excision alone, superadded portal-vein occlusion causes necrosis. Celiac artery ligation may well have merit in extending surgical therapy for gastric cancer, but this should be done with recognition that circulatory alterations may be produced.

Pyloric Stenosis and Gastric Ulcer. S. P. Rigler, H. A. Oberhelman Jr., P. H. Brasher and others. A. M. A. Arch. Surg. **71:**191-195 (Aug.) 1955 [Chicago].

Dragstedt developed the concept that gastric ulcers are usually due to a hypersecretion of gastric juice of humoral or hormonal origin dependent upon hyperfunction or dysfunction of the gastric antrum, whereas duodenal ulcers are usually due to a hypersecretion of gastric juice of nervous origin. Several attempts have been made to study the interrelation of pyloric obstruction, hypersecretion, and gastric ulcer in experimental animals. In the present study, quantitative collections of gastric secretion from Heidenhain pouches in dogs were secured for long periods of time before and after the production of stenosis at the pylorus. Pyloric stenosis was produced by one of two methods. The first method consisted of wrapping narrow bands of cellophane around the duodenum just distal to the pylorus and securing these just tight enough to hold them in place without actually occluding the lumen of the intestine. The second method involved excision of a diamond-shaped portion of the pyloric musculature comprising most of the anterior wall of the pylorus. The defect thus produced was repaired by approximating the muscularis with several interrupted chromic absorbable (gut) sutures. This operation produced marked stenosis at the pylorus. Postoperatively, collections of gastric juice were again resumed after the animals had demonstrated ability to eat and retain the standard laboratory diet. Experimental pyloric obstruction in dogs produced a marked and long-continued hypersection of gastric juice. This hypersecretion occurred in vagus-denervated Heidenhain pouches, indicating that it is of humoral or hormonal origin. Gastric ulcers developed in one animal subsequent to pyloric stenosis with resultant hypersecretion. The authors comment on the frequent occurrence of gastric ulcer in patients with preexisting duodenal ulcers of long standing with partial healing and pyloric stenosis. It is suggested that these secondary gastric ulcers are brought about by a hypersecretion of gastric juice caused by excessive antrum stimulation from contact with food and from hypermotility.

Measurement of Portal Pressure by Liver Puncture. A. Lemaire and E. Housset. Presse méd. **63:**1063-1064 (July 23) 1955 (In French) [Paris, France].

The authors used Le Go's technique of intrasplenic pressure determination for liver puncture to determine portal pressure in 44 persons. A 17/10 mm. needle is thrust into the liver as for a punch biopsy. When the point has penetrated 1 or 2 cm. into the parenchyma, the cartridge is removed and the needle attached to an aneroid manometer graduated in centimeters of water by means of a piece of rubber tubing filled with a citrated solution. In normal persons the pressure varies from 7 to 13 cm.; the average in 19 subjects was 11 cm. Twenty-five cirrhotic patients with portal hypertension had pressures varying from 27 to 45 cm. The intrasplenic pressures were also determined in these 44 persons, and the two sets of figures jibed well. These procedures are simple, give relatively accurate results, and are reasonably inoffensive to the patient. They should be used in association in order to differentiate intrahepatic and extrahepatic blocks and probably also for the recognition of certain portal and segmental hypertensions.

Total Colectomy in Ulcerative Colitis. L. S. Fallis and J. Barron. West. J. Surg. **63:**452-455 (July) 1955 [Portland, Ore.].

It is now widely accepted that, when surgical intervention is indicated in ulcerative colitis, the ultimate goal of the surgeon should be the extirpation of the entire colon and rectum. Under ideal conditions the three-fold operation of ileostomy, removal of the entire colon, and resection of the rectum may be carried out in one stage. On other occasions graded procedures will be advisable. Ileostomy alone often is a lifesaving measure, but it should be considered only as a preliminary step of a plan that ultimately will culminate in removal of colon and rectum. The authors discuss the indications for the various types of operative procedures and the complications likely to arise therefrom. A technical modification is described that accomplishes removal of the colon and rectum through an abdominal incision. This procedure was carried out on 20 patients without a death. It reduces the loss of blood and the trauma incidental to the classic perineal resection. Convalescence was rapid in all the patients, since there was no large perineal wound left to heal in slowly by granulation tissue. All the complications observed were due to difficulties associated with the ileostomy. These problems still persist, but they have been lessened by such steps as using a separate opening with circular skin incision for the ileostomy and immediate suture of the ileal mucosa to the skin margin, as advocated by Brooke and Turnbull, and finally by the application of the Rutzen bag in the immediate postoperative period.

NEUROLOGY & PSYCHIATRY

Etiology of Cerebral Palsy: An Experimental Approach. E. Denhoff and R. H. Holden. Am. J. Obst. & Gynec. **70:**274-281 (Aug.) 1955 [St. Louis].

A detailed study of 100 patients with cerebral palsy was undertaken, and the apparently significant factors in the history were isolated. The following significant obstetric and neonatal factors were selected for study: midforceps delivery, breech delivery, prolonged pregnancy, prolonged labor, prematurity, the need of oxygen or transfusion, the existence of cyanosis, hypertonicity, and listlessness. These findings were statistically of a significantly greater incidence in the histories of the 100 children with cerebral palsy than in the histories of 504 consecutive ward-births at the Providence Lying-In Hospital in 1949. Utilizing the significant findings previously listed as presumptive causes of brain damage, all the infants in the group of 504 whose histories indicated any of them were chosen for study. There were 36 infants whose histories (prenatal, obstetric, or neonatal) contained one or more of the previously mentioned "significant" findings. Each of these infants was visited by district nurses every three months for a period of two and one-half years. Only 15 of this group could be followed completely throughout the 30 month period. This group of 15 children is designated the "suspicious" group. Each child in this group was studied individually and intensively with a variety of testing instruments and conditions. A random sample of 17 children, closely matched with the 15 for sex, date of birth, and socioeconomic status, served as a control group. They differed from the "suspicious" group only by the absence of any "significant" finding in their history. The suspicious and control histories were compared with those of 20 children with cerebral palsy. Only four (27%) of the suspicious group had abnormalities in physical, psychological, and/or social development when studied at the end of 30 months. Three (18%) of the control group had similar findings. The only factor common to the abnormal children in both groups was a history of previous abortion in the mother. This seems even more striking in view of the fact that abortion is also found in a high percentage (28%) in mothers of children with cerebral palsy. The authors conclude that one important field of research in the etiology of cerebral palsy involves further investigation of reproductive physiology.

Treatment of Children in the Iron Lung. K. Stenger. Klin. Wchnschr. **33:**654-665 (July 15) 1955 (In German) [Berlin, Germany].

Stenger presents observations on 20 children with poliomyelitis who required treatment in the iron lung. The respiratory disturbance was of central origin in one child; 9 children had a purely peripheral respiratory disturbance; and in 10, bulbar, pontine, and encephalitic symptoms were combined. Division into these diverse groups is essential for the proper selection of patients for treatment in the iron lung. The bulbar forms of poliomyelitis are characterized by disturbances in swallowing, which result in the accumulation of viscid sputum in the posterior pharynx, which in turn causes obstruction of the upper air passages. Respiratory disturbances produced in this way may be confused with those that are centrally produced, but clinical examination will reveal their true nature, and measures should be taken that will keep the airway free. The respiratory disturbances of purely central origin often are an ominous sign. The involvement of the substantia reticularis and of the respiratory centers in medulla, pons, and hypothalamus produce severe arrhythmia; breathing may remain superficial despite cyanosis. Spinal paralysis of the respiratory muscles causes rather erratic symptoms, involving at times expiratory and at times inspiratory muscles and, occasionally, sparing certain segments or large groups of muscles. Life is threatened not only as the result of the defective gas exchange but also because inadequate pulmonary ventilation produces atelectasis, with its adverse effects on the circulation, particularly the right side of the heart. Oxygen deficiency results, which produces hypoxemia and cyanosis and gradually leads to disturbances in consciousness, since the myocardium and nervous system are highly susceptible to oxygen deficiency. Insufficiency of the respiratory musculature also involves deficient elimination of carbon dioxide. In describing the technique of treatment with the iron lung, the authors discuss the dangers produced by aspiration, by hypoventilation, and by hyperventilation. The following tests have proved helpful in checking the condition of the patient in the iron lung: determination of carbon dioxide in the alveolar air and of the blood pressure, electrocardiography, and measurement of oxygen saturation of the tissues and of carbon dioxide pressure in the blood. No definite rules can be made with regard to level of negative and positive pressures and frequencies in the iron lung, and various models of the iron lung require individual adjustments. At the onset of iron lung treatment, the authors administer the phenothiazine derivative, Megaphen. This drug facilitates adjustment to the rhythm of the iron lung. Tracheotomy should be done if the muscles of deglutition are paralyzed. In these cases positive pressure breathing by way of the trachea accomplishes about as much or perhaps more than iron lung treatment. In spinal respiratory paralysis, however, the iron lung method is the procedure of choice. Strophanthin is given to patients in the iron lung to prevent cardiac failure, and nikethamide (Coramine) is given for circulatory collapse of central origin.

Electroencephalographic Observations on an Alkaloid of Rauwolfia (Serpasil). S. Colombati and P. Benassi. Gazz. med. ital. **114**:69-72 (April) 1955 (In Italian) [Milan, Italy].

A comparison was made of the electroencephalograms of five healthy persons and 15 patients with epilepsy before and one hour after the intravenous administration of 3 to 5 mg. of Serpasil. A depression of the bioelectric rhythms was found after the administration of the drug in the electroencephalograms of both groups, but it was more marked in those with epilepsy. The alpha rhythm became more evident in the normal persons, whereas in the epileptic patients the altered rhythms were less sharp and more concentrated in foci. The hypersynchronism, which was especially evident in the tracings of patients with psychomotor epilepsy, tended to disappear and in the tracings of these patients the activity of the focal theta rhythms became especially evident. The activity of the drug became manifest on the electroencephalograms 15 to 30 minutes after the intravenous injection, concurrently with the clinical effects. With regard to these, a 5 mg. dose of Serpasil induced in the patient a sense of torpor and a decrease in his state of vigilance. The same dose had also the paradoxical effect of inducing a state of insomnia that was prolonged for several hours but was not accompanied by manifestations of psychic or motor reactions. The variations of the morphology of the bioelectric potentials depended on the modifications in the state of consciousness, which was disturbed by the drug.

Carotid-Artery Ligation in Surgery of the Head and Neck. O. Moore and H. W. Baker. Cancer **8**:712-726 (July-Aug.) 1955 [Philadelphia].

Ligation of either the common or the internal carotid artery may have serious and often fatal sequelae. The major hazard is the occurrence of cerebral damage, which supervened in 40 (45.4%) of 88 consecutive patients subjected to ligation of either the common or the internal carotid artery or both in the course of treatment for various lesions of the head and neck during the period from 1926 to 1952, inclusive. Cancer was the primary disease in 78 (89%); 2 had large, rapidly expanding cavernous hemangiomas, 1, an extensive schwannoma, and the other 7, carotid-body tumors. Carotid-body tumors, which were formerly considered malignant, are now believed to be benign in the great majority of cases, so that excision of the carotid bulb is not justified. Carotid ligation for these tumors has not been performed by the head and neck service of Memorial Center for Cancer and Allied Diseases, New York, since 1948. Complications and deaths following carotid ligation have shown a steady decrease throughout the years, falling from 60% and 55%, respectively, in 20 patients operated on from 1926 to 1937 to 31% and 11% in 35 patients operated on from 1948 to 1952. The importance of thrombosis and embolism as a cause of cerebral complications seems, on the basis of the autopsy findings in this series, to have been greatly overestimated. The three factors upon which every carotid ligation depends for its success are an anatomically efficient collateral pathway through the circle of Willis, the absence of abnormal segmental or diffuse arteriospasm, and the maintenance of sustained normal arterial pressure and blood volume flow. The records of these patients show that hypotension during or after the operation was the one common factor in a significant number of patients suffering major cerebral complications and that, conversely, it occurred in but a small number of those who survived carotid ligation without ill-effect. Only four patients had a significant fall in blood pressure without showing evidence of serious brain injury. More effective prevention of hypotension is believed to be chiefly responsible for the reduction of the over-all mortality from carotid ligation to 11.4% during the last five years covered by this report. Stabilization of the blood pressure at or near the patient's normal level should be accomplished before ligating either the common or the internal carotid artery whenever possible. Relative cerebral hypotension should also be avoided by keeping the patient in a recumbent position until the blood pressure is well stabilized and the danger of fainting has passed. Gradual rising under supervision may have prevented hemiplegia in at least two of these patients.

Oral Metrazol Therapy in Senility (A Preliminary Report). W. B. Suter. Dis. Nerv. System **16**:211-217 (July) 1955 [New York].

Suter was induced to use pentylenetetrazol (Metrazol) in a selected group of 15 senile patients, because of the success that Chesrow and others had reported in 1951 with the oral use of this drug in aged and confused patients. This drug is a restorative, potent analeptic, and central nervous stimulant. Its action is primarily on the higher centers, cortex, thalamus, and medulla, but all parts of the cerebrospinal axis are stimulated to some degree. Metrazol acts particularly on the respiratory, vasomotor, and vagal centers when these centers are depressed either physiologically or by drugs. It stimulates reflex activity of the spinal cord, seems to enhance autonomic activity directly and in response to afferent stimulation, and stimulates nerve impulse transmission across the ganglionic synapses. The 15 men, ranging in age from 67 to 83 years, were selected because all showed marked senile mental disturbances. Nearly all of them were disoriented, confused, often restless, untidy, and quarrelsome. They had been in the institution for years without changes in their personality, so that changes following any form of therapy might be assumed to be the result of the inaugurated treatment. Generally, two tablets of 1.5 grains (0.09 gm.) each were given three to four times a day. Twelve of the 15 patients were definitely improved even after so short a time as four to five weeks. Usually improvement occurred within 10 to 14 days after the therapy was started. Two patients became definitely more alert mentally—one of them even requested permission to go home and was later discharged. Ten became more amenable to ward care, so that restraint could often be dispensed with and the constant aimless wandering about the ward ceased. What can be achieved with Metrazol therapy in mentally less confused patients remains to be seen. Judging from the results so far, it reduces the nursing difficulties inherent in the care of senile patients.

Experiences in Surgical Treatment of Lumbar Disk Herniation. O. Svaar. Acta chir. scandinav. 109:97-105 (No. 2) 1955 (In English) [Stockholm, Sweden].

Svaar presents observations on 157 patients in whom herniation of a lumbar disk had been treated by surgical extirpation. The periods of postoperative observation ranged from six months to seven years. Four of the patients were operated on a second time, from 12 to 30 months after the first operation, three for herniation of another disk and the fourth because cicatricial tissue caused pressure on a nerve root and recurrent radicular pain. As regards the indications for operation, the author says that most patients had a long history of frequent recurrences that had not responded to conservative treatment in the form of prolonged bedrest or the wearing of supports. In three patients the onset had been sudden with nerve root pain, which was followed within a few days by paralysis of muscle groups; it is generally agreed that prognosis is unfavorable in these cases, unless surgery is carried out promptly. The author always carried out Abrodil myelography prior to operation. Intradural tumors of the cauda were found in 2% of the positive myelograms. Myelography is also important for the detection of multiple herniations. Furthermore, the author is convinced that, owing to the routine use of myelography, he has avoided surgery in many patients who should not be operated on. Normally he resorts to surgical treatment two or three days after the myelography. Exposure of the prolapse was usually carried out by partial hemilaminectomy or arcotomy, that is, extirpation of the ligamentum flavum and chiselling off of a small part of the upper and lower edges of the arches. In a few cases total laminectomy was performed. Extradural removal was carried out in all but eight of the patients. After removal of the herniation, the disk was scraped and all degenerated pulpal tissue was removed; this is important in order to avoid recurrence. Thorough hemostasis before closure of the wound is important to prevent subsequent cicatricial root compression. The author never performed spine fusion in connection with the operation. In the follow-up, 27 patients were reexamined by the author, and 120 answered a questionnaire. The results obtained were excellent in 74.8% and good in 13.7%; improvement was obtained in 5.4%; and only 6.1% of the patients are still partially or completely disabled. In view of these results the author feels that lumbosacral fusion is not necessary in all cases of lumbar disk herniation but should be reserved for those few patients in whom the spine fails to stabilize after the disk operation.

Skin Temperature in Relation to Nerve Injuries in Man. H. Shapiro and E. K. Stoner. Angiology 6:227-252 (June) 1955 [Baltimore].

When a peripheral nerve is sectioned, changes occur in both the sudomotor and the vasomotor control of the area the innervation of which has been interrupted. The validity of the use of the skin temperature as a measure of blood flow in the skin has been analyzed by other investigators. The authors of this report studied 25 patients with peripheral nerve injuries of the upper and lower extremities, using skin temperature as an indicator of vasomotor control. The patients were all young men. It was found that vasodilatation may exist for many months after peripheral nerve injury or after surgical sympathectomy. When a peripheral nerve has been completely severed, the cutaneous vessels supplying the autonomous zone are generally dilated as compared with the normally innervated area. Such dilatation exists because of the interruption of the action of the normal vasoconstrictor fibers. These fibers are carried in the major nerve trunks, along with sensory and motor fibers of the voluntary nervous system. In patients in whom all vessels are dilated, the separation of the injured zone from normal zone vessels may be achieved by a cold immersion test, using contralateral extremities. A severe crushing injury may result in motor weakness, yet leave much of the autonomic vasomotor control unimpaired. The change in deep body temperature (as measured with a suitably designed rectal thermocouple) required to bring about vasomotor activity may be as small as 0.1° C (1.8° F). The authors feel that these data are in agreement with the view that the control of peripheral vessel caliber is mediated through autonomic fibers whose activity induces vasoconstriction and that vessel dilatation is largely due to the inhibition or hypofunction of these vasoconstrictor fibers. Sensory loss (to touch and deep pressure) may be coexistent with normal vasomotor response in the affected area.

GYNECOLOGY & OBSTETRICS

Cervical Pregnancy. R. C. Cummin. Lancet 2:68-69 (July 9) 1955 [London, England].

The first pregnancy of a 20-year-old woman had terminated in a normal confinement 20 months before. When she was hospitalized on Oct. 10, 1954 because of vaginal bleeding, she stated that she had had her last menstrual period on July 12, 1954. She had not felt well during this pregnancy owing to continuous vague lower abdominal pain. She had severe backache and nausea in the early hours of the morning before admission. Some four hours later at about six o'clock, during micturition, she passed several large blood clots per vaginam. The bleeding persisted, and arrangements were made for her transfer to hospital. On inspection of the abdomen there was a swelling rising from the pelvis and reaching to the level of the umbilicus. This appeared to be bilocular. The lower swelling was symmetrical resembling a distended bladder and was softer than the upper mass to which it appeared to be attached. Fetal parts were not detected and movements had not been felt. A vaginal examination revealed the cervix to be very full, effaced, and one-finger dilated. In the anterior fornix there was a soft tender swelling and, above and to the left, a firmer mass that resembled an ovarian cyst. The findings pointed to an inevitable abortion with a possible torsion of an ovarian cyst. The woman was treated with Pethidine and Ergometrine and carefully observed. The following day there was a recurrence of abdominal pain. The bleeding was minimal and no products of conception were passed. It was decided to examine the patient under anesthesia and to perform a laparotomy, if necessary. The cervix was found to be two-fingers dilated. The softer pelvic tumor appeared to be the pregnant uterus to which was attached a much firmer swelling that resembled a fundal fibroid. A finger was introduced into the cervical canal and digital evacuation commenced. The placenta was found to be occupying the ballooned-out anterior portion of the cervix. During separation of the placenta the membranes ruptured and a fetus was extracted. At this stage the true nature of the placental implantation was detected. The cervix formed a roughly spherical cavity approximately the size of an orange, with an opening admitting the tip of the finger at its summit. This opening was the internal os with the body of the uterus above it. A blood transfusion was given, and the patient was discharged on the eighth day after operation. Three months later she stated that she had been well and that menstruation had returned. A cervical pregnancy is an unusual example of an ectopic gestation. Nearly all cervical pregnancies terminate in abortions before the 12th week of gestation, but this is not invariable and cervical pregnancies have been carried beyond the 20th week and almost to term. Hemorrhage can be most alarming and sometimes fatal. The condition is seldom recognized prior to operation and no doubt many abort spontaneously and pass unnoticed.

Idiopathic Epilepsy in Pregnancy: Summary of the Literature and Clinical Study of Twenty Patients. J. H. McClure. Am. J. Obst. & Gynec. 70:296-301 (Aug.) 1955 [St. Louis].

During the period 1950 to 1954, when there were a total of 7,379 deliveries, the authors found 20 mothers with typical grand mal attacks and without demonstrable organic changes. In addition to these 20 women, 9 others were seen with grand mal seizures in whom there was an insufficient history and diagnostic work-up for satisfactory evaluation. All patients were seen by a neurological consultant, and all received active treatment immediately upon diagnosis. Six of the 20 patients had their first medical work-up for seizures when they were seen in pregnancy. Treatment consisted of phenobarbital and diphenylhydantoin (Dilantin) sodium. Those patients in whom diphenylhydantoin caused intoxication without control of the convulsions were given either 3-methyl-5,5-phenylethylhydantoin

(Mesantoin) or an experimental anticonvulsant drug with amphetamine. The 20 women were observed during a total of 28 pregnancies. Seven of the women had one or more relatives with convulsions. The frequency of convulsive attacks increased during pregnancy in 11, remained unchanged in 5, and decreased in 4 of the women. Only one of the 28 deliveries was by cesarean section; this was done at eight months' gestation after 12 hours of status epilepticus controlled only by constant intravenous sedation, and after Pitocin infusion and rupture of the membranes had failed to induce labor. Both mother and infant survived. A patient with identical electroencephalographic findings, and also with grand mal seizures well controlled with phenobarbital and diphenylhydantoin, developed uncontrollable status epilepticus at seven and one-half months' gestation and was delivered in a moribund state by cesarean section after induction of labor had failed. She regained consciousness 48 hours later and survived, but her infant died. Idiopathic grand mal epilepsy is without effect on pregnancy except in the patient with status epilepticus; the effects of pregnancy on idiopathic epilepsy are unpredictable. The majority of women in this group had more frequent convulsions during pregnancy.

Influence of a Substance with Ganglioplegic Action (Hexamethonium Bitartrate) on Course of Labor. M. Boscaro and A. Russo. Minerva ginec. 7:410-418 (June 15) 1955 (In Italian) [Turin, Italy].

Hexamethonium bitartrate (Esonium) was administered intravenously by drip infusion in doses of 50 to 125 mg. diluted in a 5% glucose solution to 20 pregnant women at term taken at random, mainly from primigravidas who were admitted to the gynecologic clinic of the University of Turin. The influence of the drug was evaluated on the basis of modifications induced on the uterine contractions, on the length of the dilatation and expulsion stages, and on the arterial pressure. The drug had little effect in the women who received it in the prodromal stage of labor. It did have a favorable effect on the uterine contractility of women in whom labor had already begun at the time the drug was given; in these the stage of dilatation was accelerated. In women with simple or spastic inertia the basal uterine tonus was lowered, the rhythm became regular, the intensity or frequency of the contractions was increased, and a quick delivery followed. Systematic readings of the arterial pressure often revealed a parallelism between the hypotensive effect of the drug and its favorable action on the contractility of the uterus. Hypotension was never so marked as to induce fetal anoxia. The drug did not have a harmful effect on the fetus, nor did it affect the mother's cardiac activity, except for a mild sinus tachycardia, which was shown by electrocardiograms. The drug had no analgesic effect. The administration of 2 units of Pituitrin together with the ganglioplegic was especially favorable in influencing the uterine contractility, very likely because of a synergistic action of the two substances. This combination may make it possible to administer oxytocic hormone of the posterior lobe of the hypophysis even in cases, such as gestosis, in which eventual hypertensive crises could be dangerous. In such instances, the hypertensive action of the hormone would be compensated by the ganglioplegic-induced hypotension.

Heparin-like Action of Follicular Fluid of Human Ovary. G. Vecchietti. Minerva ginec. 7:327-343 (May 31) 1955 (In Italian) [Turin, Italy].

Studies made on samples of fluid taken from apparently healthy or microcystic graafian follicles or from luteofollicular cysts in 63 patients indicated that the fluid of the first two had a high anticoagulant activity. Sometimes this activity was present also in the fluid obtained from the luteofollicular cysts; fluid from these, however, could coagulate spontaneously, or, less frequently, it showed a moderate coagulation-accelerating activity. The studies revealed also the high protein content of the fluid, some electrophoretic characteristics, and the presence of fibrinogen and other coagulation factors. Numerous tests indicated that the anticoagulant activity of the fluid is of a heparin-like type; the intensity varied from patient to patient, and no particular relationship was noted between the intensity of the anticoagulant power and the various phases of the menstrual cycle. The follicular fluid had spontaneous fibrinolytic activity only in some cases of hemorrhagic luteofollicular cyst. The anticoagulant activity of the fluid was found to be the same as that of solutions containing up to 320 gammas of heparin per cubic centimeter. Protamine sulfate inactivated this anticoagulant activity, whereas toluidine blue and thionine potentiated it. An explanation for this peculiar behavior has not been reached. The follicular fluid behaved like heparin in preventing or rendering reversible the erythrocyte agglutination caused by protamine sulfate and in decreasing the platelet adhesiveness. Histochemical studies of the ovary showed a certain parallelism between the intensity of zone chromotropy, the number of mast cells, and the anticoagulant activity of the follicular fluid.

Microbial Flora in Pyosalpingitis. F. Ferraris and G. Papotti. Minerva ginec. 7:436-437 (June 15) 1955 (In Italian) [Turin, Italy].

The authors studied the bacterial and mycotic flora of 18 cases of pyosalpingitis that had been treated at first by prolonged administration of sulfonamides, antibiotics, and nonspecific proteins, and subsequently treated surgically. They found bacteria in eight cases: Micrococcus (Staphylococcus) aureus in two instances, Micrococcus albus in one, diplostreptococcus in one, hemolytic streptococcus in one, Escherichia coli in two, and Mycobacterium tuberculosis in one. M. aureus was found together with Esch. coli in one instance only. Gonococcus, which together with Esch. coli was in the past the commonest finding in this condition, was not found. Nor were there any mycotic micro-organisms.

PEDIATRICS

Epidemic Nephritis at Red Lake, Minnesota. C. R. Reinstein. J. Pediat. 47:25-34 (July) 1955 [St. Louis].

Acute glomerulonephritis, like rheumatic fever, is considered a nonsuppurative complication of infection by the beta hemolytic streptococcus, group A. Whereas rheumatic fever occurs in a relatively constant incidence of about 3%, regardless of serologic type or clinical manifestations of the antecedent infection, nephritis is characterized by an extremely variable attack rate. Although usually sporadic, nephritis may appear from time to time in widespread epidemics, in localized outbreaks, and in families. Investigators have found evidence to suggest that differences in epidemiologic features between rheumatic fever and nephritis may be explained by variations in bacterial factors. It is thought that, although most, perhaps all, types of group A streptococci can produce rheumatic fever, only a few may be nephritogenic. This report is concerned with an outbreak of nephritis on the Red Lake Indian Reservation in northern Minnesota during the summer and fall of 1953. The clinical aspects of this epidemic, which involved 63 cases, were described previously. This paper is concerned with epidemiologic studies in 56 of the patients who had classical acute glomerulonephritis. In six of the seven patients not included in this study the symptoms were subsiding and in the seventh patient, the disorder was complicated by hepatitis. The ages of all but two of the 56 patients ranged from 1 to 8 years, the average being 4 years. In 80% of the patients a unique type of pyoderma was also present. Scarlet fever preceded some cases. To determine the etiological agent, nose and throat cultures were taken from 350 individuals: 216 at Red Lake Reservation (51 nephritic patients, together with contacts and suspects, and a control series of 134 first-grade school children [63 from Red Lake and 71 from Cass Lake]). Pyodermatous lesions of 26 individuals, including 12 with nephritis, also were cultured. Beta hemolytic streptococcus was found in 22.4% of the 216 subjects at Red Lake and in 24.2% of the 63 first-grade school children at Red Lake, but in only 12.7% of those from Cass Lake. Cultures of the pyodermatous lesions showed beta hemolytic streptococci, group A, in 53.8% of the patients. All group A organisms were untypable against known antiserums. Over 70% of the Red Lake population was given prophylactic treatment to control the epidemic. Benzathine penicillin was administered by injection, in a single dose of 600,000 units to each subject less than 15, and 1,200,000 units to those of 15 years or older. Previous to injection, nose and throat cultures were taken from about 500 of the persons who were to receive prophylaxis. A new culture test was made one month later in as many as possible, and 381 paired cultures were thus available. Cultures were positive for the beta hemolytic streptococcus in 20.7% before prophylaxis, and, on reculture, only 1.3% were positive. All positive cultures at the first sampling were negative at the second. Of cultures before prophylaxis, 10.8% were group A, untypable; after prophylaxis, untypable strains of group A were present in only 0.3%. Mass prophylaxis with benzathine penicillin aborted, within two weeks, an epidemic of nephritis apparently caused by a previously unidentified strain of the beta hemolytic streptococcus, group A, with strongly nephritogenic properties. Acute glomerulonephritis, therefore, is a preventable disease.

Electroencephalographic Studies Following Pertussis Immunizations. N. L. Low. J. Pediat. **47**:35-39 (July) 1955 [St. Louis].

The author reviews earlier reports on severe neurological reactions to pertussis vaccine, pointing out that the main neurological symptoms are changes in consciousness varying from marked drowsiness to deep coma and convulsions. Considering the large number of babies that receive active immunizations for pertussis every year, the number of affected children is small but the outlook for these children is so bad that this problem needs more study. The case of a 6-month-old girl infant is presented in whom a convulsion developed 12 hours after she was given 0.5 cc. of alum-precipitated DPT into the right deltoid area. When she was brought back for her second injection one month later she appeared normal and her mother failed to mention the convulsion after the first injection. Twelve hours after the second injection had been made into the left deltoid region, convulsions started for which she was hospitalized. Despite treatment a state of decerebrate rigidity and convulsions continued, and the child died. A study was undertaken to ascertain whether evidence of changed cerebral physiology due to pertussis vaccinations could be found more often than clinically recognizable symptoms. Electroencephalograms were recorded before and after pertussis immunizations in 83 children between the ages of 2¾ and 16 months. Forty-three children had been injected with plain pertussis vaccine containing 30 billion organisms, and the remainder received material containing 15 billion organisms with diphtheria and tetanus toxoid. One of the babies showed marked diffuse slowing after the injection, which disappeared after one week; another showed less marked slowing with fever as the only symptom. This study shows that mild, but possibly significant, cerebral reactions occur in addition to the reported very severe neurological changes. The author feels, however, that the risk of serious neurological complications from pertussis is infinitely greater than the risk from preventive immunizations, so these injections should not be abandoned, but the material should be made safer.

Infants with Organic Heart Defect. C. Bruins. Maandschr. kindergeneesk. **23**:181-191 (June) 1955 (In Dutch) [Leyden, Netherlands].

Bruins reviews the various syndromes resulting from organic heart defects on the basis of observations on 78 children who entered his clinic before they had completed their first year of life. Of this number 38 are alive and 40 are dead. Bruins recommends periodical control examinations with telecardiography and electrocardiography for all infants with a definite precordial murmur. If changes occur or if the child shows signs of cardiac incapacity, a more thorough examination should be made. Sometimes phonocardiography is an adequate means of diagnosis, otherwise angiocardiography or arteriography may be of great help, but these drastic procedures should be kept to a minimum. However, early diagnosis may depend on these examinations, and their prognosis is better than that of a thoracotomy. Provided the anesthesia is in capable hands, infants usually tolerate these examinations well. Early operation is rarely necessary in infants with pulmonary or aortic stenosis. However, if coarctation is associated with considerable cardiac enlargement, preponderance of the left side in the electrocardiogram, and cardiac failure, then early surgical treatment is advisable. When the pulmonary circulation is overburdened and there is no cyanosis, a septal defect is usually present, and early diagnosis and treatment is advisable, particularly when the heart is enlarged, with a big pulmonary conus, pulmonary hyperemia, and hypertension. Infants with a systolic precordial murmur and with impaired ventilation of the left lung are apt to have a large patent ductus arteriosus. Early closure of it may prevent progressive obstructive changes in the arteries of the lung. In the group of children with reduced pulmonary circulation with cyanosis, that is, in those with pulmonary stenosis and septum defect, early operation is indicated only if there are alarming attacks of paroxysmal dyspnea; otherwise it is better to postpone the operation until the children are older. Anoxia with paroxysmal dyspnea may be precipitated in the first months of life by closure of an originally patent ductus. In such cases one may be sure that a pulmonary artery of good caliber is present. The type of operation (anastomosis) depends on the presence of a right-sided or left-sided aortic arch. Increased pulmonary circulation with cyanosis is caused by a variety of anomalies, usually involving transposition of the great vessels. These severely incapacitated children require early examination and diagnosis.

Melena Neonatorum: An Experimental Study of the Effect of the Oral Administration of Blood on the Stools. L. Apt. J. Pediat. **47**:1-5 (July) 1955 [St. Louis].

Many obstetricians and pediatricians believe that grossly bloody stools passed by a newborn infant in the first or second day of life might be the result of the ingestion of maternal blood during labor. In order to determine whether blood introduced into the stomach of a newborn infant could produce grossly bloody stools the author gave to normal infants by gavage from 15 to 40 ml. of blood, taken from adults or the cords of newborn infants. The blood was collected in bottles containing either dry oxalate salts or anticoagulant acid citrate dextrose Solution A (1.2 ml. for each 10 ml. of blood). A relatively large amount of blood (35 to 40 ml.) was necessary to produce grossly bloody stools in the majority of infants. The grossly bloody stools were noted as early as 9 hours and as late as 30 hours after the introduction of blood into the stomach. Grossly bloody stools were passed for 12 to 45 hours. Occult blood (guaiac test) was detected in stools within 7 hours and was present for as long as 87 hours after blood had been given. A similar study was made in older newborn infants who had evacuated their meconium. The amount of blood given was 10 to 20 ml. Much less blood (10 ml.) produced grossly bloody stools. Both grossly bloody stools and occult blood appeared as early as two and one-half hours after the administration of blood. The passage of grossly bloody stools continued for as long as 15 hours. A positive guaiac test for occult blood persisted for a period up to 46 hours. The guaiac test for occult blood was performed on all the stools passed by 35 normal newborn infants during their five day hospitalization. In all instances the test was negative. Although the number of infants in the study was too small to enable one to draw definite conclusions, the results may be of help to the clinician who may assume that the persistence of grossly bloody stools and a positive chemical test for blood indicate that there is continuing hemorrhage into the digestive tract of a newborn infant. The evidence presented indicates that this may not be true.

Protection of Children of Tuberculous Parents. M. Graffar and M. Asiel. Acta tuberc. belg. **46**:182-206 (June) 1955 (In French) [Brussels, Belgium].

A study was made of 166 children from Brussels families in which at least one of the parents had pulmonary tuberculosis. Eighty children had been protected by isolation or hospitalization of the affected parent. The former procedure (Grancher's method) was generally unsuccessful because of the parents' unwillingness to be separated from their children. Only 22 children had had this method applied correctly, and they had received adequate protection from tuberculosis. In 1954, when the average age of the 80 children was 8 years, 65% of them had positive reactions to tuberculin; 12% had had benign tracheobronchial adenopathy; 15% had had primary infections

(Mesantoin) or an experimental anticonvulsant drug with amphetamine. The 20 women were observed during a total of 28 pregnancies. Seven of the women had one or more relatives with convulsions. The frequency of convulsive attacks increased during pregnancy in 11, remained unchanged in 5, and decreased in 4 of the women. Only one of the 28 deliveries was by cesarean section; this was done at eight months' gestation after 12 hours of status epilepticus controlled only by constant intravenous sedation, and after Pitocin infusion and rupture of the membranes had failed to induce labor. Both mother and infant survived. A patient with identical electroencephalographic findings, and also with grand mal seizures well controlled with phenobarbital and diphenylhydantoin, developed uncontrollable status epilepticus at seven and one-half months' gestation and was delivered in a moribund state by cesarean section after induction of labor had failed. She regained consciousness 48 hours later and survived, but her infant died. Idiopathic grand mal epilepsy is without effect on pregnancy except in the patient with status epilepticus; the effects of pregnancy on idiopathic epilepsy are unpredictable. The majority of women in this group had more frequent convulsions during pregnancy.

Influence of a Substance with Ganglioplegic Action (Hexamethonium Bitartrate) on Course of Labor. M. Boscaro and A. Russo. Minerva ginec. 7:410-418 (June 15) *1955* (In Italian) [Turin, Italy].

Hexamethonium bitartrate (Esonium) was administered intravenously by drip infusion in doses of 50 to 125 mg. diluted in a 5% glucose solution to 20 pregnant women at term taken at random, mainly from primigravidas who were admitted to the gynecologic clinic of the University of Turin. The influence of the drug was evaluated on the basis of modifications induced on the uterine contractions, on the length of the dilatation and expulsion stages, and on the arterial pressure. The drug had little effect in the women who received it in the prodromal stage of labor. It did have a favorable effect on the uterine contractility of women in whom labor had already begun at the time the drug was given; in these the stage of dilatation was accelerated. In women with simple or spastic inertia the basal uterine tonus was lowered, the rhythm became regular, the intensity or frequency of the contractions was increased, and a quick delivery followed. Systematic readings of the arterial pressure often revealed a parallelism between the hypotensive effect of the drug and its favorable action on the contractility of the uterus. Hypotension was never so marked as to induce fetal anoxia. The drug did not have a harmful effect on the fetus, nor did it affect the mother's cardiac activity, except for a mild sinus tachycardia, which was shown by electrocardiograms. The drug had no analgesic effect. The administration of 2 units of Pituitrin together with the ganglioplegic was especially favorable in influencing the uterine contractility, very likely because of a synergistic action of the two substances. This combination may make it possible to administer oxytocic hormone of the posterior lobe of the hypophysis even in cases, such as gestosis, in which eventual hypertensive crises could be dangerous. In such instances, the hypertensive action of the hormone would be compensated by the ganglioplegic-induced hypotension.

Heparin-like Action of Follicular Fluid of Human Ovary. G. Vecchietti. Minerva ginec. 7:327-343 (May 31) 1955 (In Italian) [Turin, Italy].

Studies made on samples of fluid taken from apparently healthy or microcystic graafian follicles or from luteofollicular cysts in 63 patients indicated that the fluid of the first two had a high anticoagulant activity. Sometimes this activity was present also in the fluid obtained from the luteofollicular cysts; fluid from these, however, could coagulate spontaneously, or, less frequently, it showed a moderate coagulation-accelerating activity. The studies revealed also the high protein content of the fluid, some electrophoretic characteristics, and the presence of fibrinogen and other coagulation factors. Numerous tests indicated that the anticoagulant activity of the fluid is of a heparin-like type; the intensity varied from patient to patient, and no particular relationship was noted between the intensity of the anticoagulant power and the various phases of the menstrual cycle. The follicular fluid had spontaneous fibrinolytic activity only in some cases of hemorrhagic luteofollicular cyst. The anticoagulant activity of the fluid was found to be the same as that of solutions containing up to 320 gammas of heparin per cubic centimeter. Protamine sulfate inactivated this anticoagulant activity, whereas toluidine blue and thionine potentiated it. An explanation for this peculiar behavior has not been reached. The follicular fluid behaved like heparin in preventing or rendering reversible the erythrocyte agglutination caused by protamine sulfate and in decreasing the platelet adhesiveness. Histochemical studies of the ovary showed a certain parallelism between the intensity of zone chromotropy, the number of mast cells, and the anticoagulant activity of the follicular fluid.

Microbial Flora in Pyosalpingitis. F. Ferraris and G. Papotti. Minerva ginec. 7:436-437 (June 15) *1955* (In Italian) [Turin, Italy].

The authors studied the bacterial and mycotic flora of 18 cases of pyosalpingitis that had been treated at first by prolonged administration of sulfonamides, antibiotics, and nonspecific proteins, and subsequently treated surgically. The evidence presented indicates that this may not be true.

Protection of Children of Tuberculous Parents. M. Graffar and M. Asiel. Acta tuberc. belg. **46**:182-206 (June) 1955 (In French) [Brussels, Belgium].

A study was made of 166 children from Brussels families in which at least one of the parents had pulmonary tuberculosis. Eighty children had been protected by isolation or hospitalization of the affected parent. The former procedure (Grancher's method) was generally unsuccessful because of the parents' unwillingness to be separated from their children. Only 22 children had had this method applied correctly, and they had received adequate protection from tuberculosis. In 1954, when the average age of the 80 children was 8 years, 65% of them had positive reactions to tuberculin; 12% had had benign tracheobronchial adenopathy; 15% had had primary infections severe enough to necessitate a long period of bedrest; and 12% had lesions of secondary or tertiary tuberculous dissemination. Two children were dead of tuberculous meningitis. Half this group had spent time in preventoriums or sanatoriums amounting to more than a year per child. The second group, i. e., 86 children, had been given BCG vaccination. It was strictly comparable to the first group with regard to socioeconomic background, environment, and chance for tuberculous contact. For purposes of comparison, the 140 children from the entire group who had not reached the age of 10 were chosen. Of these, 85 had been vaccinated and 55 had not. Tuberculous morbidity was four times less in the vaccinated children than in the nonvaccinated. If only those lesions severe enough to require a long period of bedrest are considered, the morbidity was seven times less. No secondary or tertiary lesions were found among the BCG-vaccinated children, while in the control group 9% had miliary or meningeal tuberculosis. Thus it is once again proved that BCG confers remarkable protection, especially from the severer forms of tuberculosis. This protection is not absolute, and other precautions for the safety of children in contact with tuberculars must not be abandoned.

Endocardial Fibroelastosis. *E. G. St. John and T. A. Cope Jr.* Am. J. Roentgenol. **74**:39-45 (July) 1955 [Springfield, Ill.].

Endocardial fibroelastosis is one of the common types of fatal heart disease in infants, but its cause is unknown. It seems to be congenital rather than inflammatory and is probably based on anoxia. The clinical features fall into two principal patterns. The first is found in infants, usually less than 6 months of age, who have apparently been in good health until a sudden attack of severe dyspnea, cough, vomiting, and tachycardia appear. Those in the second group have episodes of mild dyspnea, with refusal to take food, vomiting, failure to gain weight, and recurrent pulmonary infections. Murmurs are usually absent. The fatal attack in these children commonly occurs within two years. Cyanosis is not a constant finding, except in patients in whom the aortic valve is affected. Involvement of the aortic valve is an ominous sign. Cardiac enlargement, often of a globular type, has been found in almost all the reported cases, almost always on the left side and principally in the left ventricle. The responsibility for early diagnosis rests heavily on the roentgenologist, but it should be remembered that the diagnosis can seldom be established with certainty during life. The characteristic cardiomegaly and the hyperplasia of the fibrous and elastic components of the endocardium were shown in the roentgenograms and demonstrated at autopsy in two infants studied at the Binghamton City Hospital. Their clinical course was marked by attacks of dyspnea and cyanosis, eventually ending in death.

Escherichia Coli O 127:B_8, a Pathogenic Strain Causing Infantile Diarrhea: I. Epidemiology and Bacteriology of a Prolonged Outbreak in a Premature Nursery. *C. S. Stulberg, W. W. Zuelzer, A. C. Nolke and A. L. Thompson.* A. M. A. Am. J. Dis. Child. **90**:125-134 (Aug.) 1955 [Chicago].

Bacteriological, epidemiological, and clinical data are presented on an extensive epidemic of diarrhea of newborn infants that occurred in the premature nursery of the Children's Hospital of Michigan and was caused by a newly described pathogen Escherichia coli O 127:B_8. The epidemic, which involved a total of 60 cases over a period of four months, was characterized by a cyclic series of flare-ups. Because stool specimens and daily cultures of the predominant organisms were systematically saved from each infant until the identity of the causative agent could be established, it became possible, with a specific antiserum, to make a complete study of the epidemic, using this organism as an etiological tracer. The bacteriological basis for the cyclic pattern of the epidemic then became apparent. Each cycle began with a build-up period during which cross infections and incubation stages were occurring. The incidence of diarrhea increased slowly at first and then rose sharply to a peak. Each sick infant exhibited virtually pure cultures of E. coli O 127:B_8 in its stools. Treatment of the sick infants with neomycin resulted in prompt individual improvement and in a sharp decline of the outbreak, which coincided with the disappearance of E. coli O 127:B_8 from the stools. With the cessation of the antibiotic treatment, a new cycle began. There was an almost immediate resurgence of the pathogenic organisms in the stools, resulting invariably in asymptomatic carriers, a few clinical relapses, and an increase in new diarrhea cases. Control of the epidemic was not accomplished until all infants, whether they had diarrhea or not, were simultaneously placed on neomycin therapy, thus eliminating the organisms from the nursery. Regarding control of pathogenic coli infections on infant units of any type, it is evident that adequate bacteriological diagnosis is a prerequisite. Rapid identification of the offending organism either by the institutional laboratory or by a centralized service such as a public health laboratory is essential. For the strains thus far shown to be associated with diarrheal disease, polyvalent serums can provide a rapid screening test, which can be followed by exact identification with type-specific serum and bacteriological analyses. When an as yet unknown strain is involved, the preparation of an antiserum against the predominant organisms and the preservation of current stool specimens is imperative. At the same time a trial with a suitable antibiotic is clearly indicated but should not be restricted to the obviously affected patients. Every patient in the unit should receive prophylactic treatment either until discharge or until bacteriological identification and control of the organisms has been achieved. Diarrhea caused by pathogenic E. coli should be made a reportable communicable disease.

Ulcerative Colitis in Children: Observations in Selected Patients. J. B. Kirsner, H. F. Raskin and W. L. Palmer. A. M. A. Am. J. Dis. Child. **90**:141-152 (Aug.) 1955 [Chicago].

Ulcerative colitis in children is not uncommon and follows a course similar to that in adults. The disease should be suspected in patients with unexplained fever, anemia, and abdominal pain, with or without bloody diarrhea. Four selected cases in two boys and two girls between the ages of 10 and 16 years are described in detail, illustrating certain psychiatric and therapeutic aspects, as well as various complications such as rectovaginal fistula, electrolyte disturbances, and amyloidosis with adrenal insufficiency. The clinical course in these patients again emphasizes the importance of prolonged, comprehensive medical treatment, skillful psychotherapy, the adjunct value of steroid therapy, and, in one patient, the lifesaving role of surgery.

Insufflated Pulmonary Tuberculous Cavitation in Infants. J. Albós Martínez and O. Cassassas. Med. clín. **24**:352-354 (May) 1955 (In Spanish) [Barcelona, Spain].

Streptomycin and isoniazid when administered simultaneously to infants with pulmonary tuberculosis and cavitation cause complete elimination of parenchymal or intracavitary exudates. However, the combined treatment may transform the lesions or cavities into pulmonary air cysts with extremely fine walls. The fatal complications that follow the development of air cysts are insufficient arterialization of blood, acute displacement of the mediastinum, and cachexia. The subjects of this report were two infants 8 and 9 months old respectively. They were admitted to the hospital with acute bronchitis that was controlled with penicillin. The Mantoux test became positive and tubercle bacilli were identified in the gastric contents. One of the patients had a tracheobronchial adenopathy. A few months after the patients had been discharged from the hospital, they were brought back with bronchopneumonia that did not respond to penicillin or sulfonamides. Roentgen examination of the chest of the patients showed exudative pulmonary lesions in one and pulmonary cavitation with an insufflated cavity in the other. The combined streptomycin-isoniazid treatment was promptly followed by apparent clinical improvement and cleaning of exudates from lesions and of cavities, all of which became transformed into air cysts. The insufflated cavity of one of the patients became so large an air cyst that it caused displacement of the spleen and acute deviation of the mediastinum. The large air cyst suddenly ruptured into the pleura causing acute spontaneous pneumothorax. The general state of health rapidly deteriorated after appearance of air cysts in both patients. Both patients died and the necropsies showed multiple air cysts of various sizes of typical aspect with thin layers of epithelium and also minimal parenchymal spots of miliary tuberculous lesions.

Deforming Osteochondrosis of the Tibia (Blount) in Children. J. E. Enklaar. Maandschr. kindergeneesk. 23:235-238 (July) 1955 (In Dutch) [Leyden, Netherlands].

Enklaar is concerned with the tibial osteochondrosis that causes bowlegs, pointing out that Blount and Langenskiöld studied this disorder under the term tibia vara in 17 cases. The author objects to this term, because it might create the impression that the lesion is always in the medial half of the knee, whereas lateral localization is possible, and this would lead to the development of genu valgum (knock knee). He observed two children with knock knees in whom roentgenography revealed the typical picture of osteochondrosis in the lateral half of the proximal ends of the tibia. He feels that, depending on the localization of the osteochondrotic process, the terms medial or lateral osteochondrosis of the tibia should be used. No evidence of tuberculosis or rickets is found in children with this disorder, but obesity generally exists and the defect usually becomes evident between the first and second years of life, soon after the child begins to stand and to walk. The author presents the history of a 3-year-old girl with nonrachitic bowlegs. He stresses the importance of roentgenologic examination, since without it the bowlegs may be assumed to be of rachitic origin. Children between 1 and 6 years of age, who have knock knees or bowlegs should always be subjected to roentgen examination so that the osteochondrotic process will be discovered and proper therapeutic measures may be taken. In children under 6 years of age, progressive correction with conservative measures is generally preferred, except when the tibial deformity is severe, in which case osteotomy may be necessary. In children over 6 years of age this operation is usually necessary.

Studies on Agammaglobulinemia: II. Failure of Plasma Cell Formation in Bone Marrow and Lymph Nodes of Patients with Agammaglobulinemia. R. A. Good. J. Lab. & Clin. Med. 46:167-181 (Aug.) 1955 [St. Louis].

Clinical, pathological, and hematological studies in human beings have provided evidence that links plasma cell formation to the elaboration of gamma globulin and the synthesis of antibody. Patients have been observed whose principal abnormality is a deficiency of both antibody and gamma globulin production and whose disorder has been designated as agammaglobulinemia. This disease occurs in a congenital, sometimes familial, form, which probably represents an inborn error of metabolism transmitted as a sex-linked recessive trait, or it may occur in an acquired form that may appear at any age and in either sex. The author compared the bone marrow and lymph nodes of four patients with agammaglobulinemia with similar tissues from normal persons and found a deficiency of plasma cells in the tissues of patients with agammaglobulinemia. Normal children showed plasmacytosis of the bone marrow and regional lymph nodes after stimulation with antigens, and there was evidence that plasmacytosis of the draining node in normal children is greater during the anamnestic reaction than during the primary response to antigen. Lymph nodes of patients with agammaglobulinemia tend to be small and poorly developed and have a relatively thin cortex with few germinal centers. Evidence is presented indicating that lymph nodes and bone marrows of patients with agammaglobulinemia are characterized by failure to develop plasma cells and secondary follicles in response to both primary and secondary antigenic stimulation. The author feels that these observations support the concept that plasma cells are directly involved in the sequence of events resulting in the formation of antibodies and gamma globulin and the liberation of these proteins into the circulating blood.

DERMATOLOGY

The Significance of a Positive L. E. Phenomenon. R. S. Weiss and S. Swift. A. M. A. Arch. Dermat. 72:103-112 (Aug.) 1955 [Chicago].

The authors studied the blood of 350 patients. They found L. E. cells only when lupus erythematosus was the leading or a possible diagnosis, but they also observed certain other changes in some of these bloods, such as the so-called tart cell, a histiocyte that has engulfed a dead or damaged white cell. The latter is usually a lymphocyte, and it retains some of its nuclear outline and chromatin pattern. It is often difficult to distinguish between tart cells and true L. E. cells. The difference lies in the fact that the true L. E. cell is a homogeneous smoky body, completely without nuclear structure, while the inclusion body in the tart cell retains an outline and some chromatin network (nucleophagocytosis). The authors gained the impression that these tart cells may be precursors or perhaps abortive forms of L. E. cells. While the presence of these cells should not be regarded as evidence of the L. E. phenomenon, they are suspicious, and repeated tests should be made. The authors found no L. E. cells in blood specimens from patients with penicillin hypersensitivity, although, since lupus erythematosus is regarded as possibly a hypersensitivity phenomenon, L. E. cells might be found in severe and long-standing penicillin reactions. The production of the L. E. phenomenon by hydralazine (Apresoline) is highly interesting. The L. E. phenomenon was observed in 3 of 16 blood preparations made in patients receiving hydralazine, in whom some symptoms had developed in response to the drug. L. E. cells and other stigmas of the L. E. phenomenon were found in patients with rheumatoid arthritis often enough for this disease to be considered as a possible manifestation of lupus erythematosus. Although discoid lupus erythematosus can become disseminated, the authors found L. E. cells in only 2 of 55 patients with discoid lupus erythematosus. They feel that reports about the discovery of L. E. cells in fungus diseases may be due to the fact that nucleophagocytosis (tart cells) were mistaken for L. E. cells, they themselves having done this before a strict differentiation had been made between the two. They conclude that, while positive tests have been reported in a number of other diseases, the presence of clumping rosettes and the typical L. E. cell may be taken as conclusive evidence of systemic lupus erythematosus. The test is practically always positive at some time during the course of lupus erythematosus. Its value, however, is greatest in the borderline cases, and, if the L. E. cell is found in certain rheumatic states, the burden of proof lies on him who would say that the condition is not systemic lupus erythematosus. All patients with rheumatoid arthritis should have frequent L. E. tests performed, especially if they show symptoms suggestive of lupus erythematosus such as mild bouts of fever, pain, reversal of the albumin/globulin ratio, microscopic evidence of kidney involvement, and increased sedimentation rate. The fact that the authors found one or two L. E. cells in the blood of patients who did not seem ill, coupled with the fact that the hydralazine syndrome seems to be reversible, makes them think that perhaps lupus erythematosus is not always a fatal disease.

Aminopterin for Psoriasis. R. B. Rees, J. H. Bennett and W. L. Bostick. A. M. A. Arch. Dermat. 72:133-143 (Aug.) 1955 [Chicago].

Aminopterin (4-amino-pteroylglutamic acid) is known to exert a favorable effect on the lesions of psoriasis, but it is a dangerous drug, since the range between beneficial and toxic doses is narrow. The authors used moderate doses of Aminopterin in 171 ambulatory patients with psoriasis, hoping to clear or improve the lesions of psoriasis without producing too high an incidence of toxic effects. All of the patients had received one or several forms of conventional therapy, usually over a period of many years. The patients were not selected, except that treatment was not given during pregnancy, because the drug has an abortifacient effect. The group included 94 males and 77 females. The average duration of the disease was 10 years. Several treatment schedules were tried. It was found that when Aminopterin was used in a dose of 0.5 mg. daily by mouth, not exceeding 6 mg. over a period of 12 to 20 days, clearing or great improvement of psoriatic lesions occurred in approximately 80% of the patients with an 8% incidence of toxic reactions. The toxic effects were slight and transitory on this schedule. Relapses, however, were frequent, and usually occurred within from two weeks to two months. It remains to be determined whether the lesions of psoriasis can be completely suppressed by repeating the small doses of Aminopterin from time to time and also whether this repeated administration will have toxic effects. There is no evidence of ill-effect, hematological or otherwise, in a few patients treated with from 30 to 50 mg. over a six months' period with the aforementioned dosage schedule. When more than 0.5 mg. is given daily, the toxic effects are more frequent and severe.

Developments in Rotary Abrasive Technics for Removing Acne Scars and Other Cosmetic Defects. J. J. Eller. New England J. Med. **253**:11-14 (July 7) 1955 [Boston].

According to Eller the following types of rotary abrasives have been used for the removal of pitted acne scars and of other cosmetic defects: heatless stones, steel burrs, steel-wire brushes, and diamond and ruby fraises powered by high-speed rotary motors. He previously reported observations on 200 patients in whom he used rotary steel-wire brushes with a velocity of 12,000 rpm under ethyl chloride refrigeration anesthesia in which good cosmetic results were obtained. This technique had certain disadvantages. Recently he has been using the Schreus high-speed apparatus (30,000 rpm) with heatless stones, steel burrs, and diamond and ruby fraises in hundreds of cases, with most satisfactory results. He found that the heatless stone and diamond and ruby fraises, powered by a high-velocity motor capable of 30,000 rpm, gave a much smoother grinding, a more satisfactory dermal abrasion, and better cosmetic results than the steel-wire brushes, driven by lower-velocity motors of 12,000 rpm. When the high-speed (Schreus) grinders are used it is not necessary to harden the skin, and therefore it is possible to use procaine-Cobefrin local anesthesia. With this anesthetic the field is always visible and not disguised as by freezing, which is most advantageous when small lesions, facial contours, linear scars, pigmentations, and tattoo marks are being abraded. In cases of dermal abrasion in which refrigeration anesthesia is desirable, Freon Mixture is preferable to ethyl chloride, since it is nonexplosive and nontoxic.

UROLOGY

Bilateral Total Adrenalectomy in Diabetics with Degenerative Vascular Disease. J. W. Headstream and J. T. Wortham. J. Urol. **74**:1-7 (July) 1955 [Baltimore].

Patients with diabetes mellitus have a tendency to premature development of arteriosclerosis. Microaneurysms of the retinal arterioles are usually the earliest manifestations of diabetic vascular degeneration. Later, the changes are often greatest in the kidneys. One stage of this renal vascular deterioration was defined by Kimmelstiel and Wilson as intercapillary glomerulosclerosis. The advanced stage of renal deterioration is characterized by hypertension, vascular accidents, nitrogen retention, proteinuria, hypercholesteremia, eventual renal failure, and death. Previous publications provide evidence that altered adrenal cortical function resulting from complications of diabetes may well be responsible for arteriolar degeneration. There is evidence that insulin hypoglycemia is a stimulant of adrenal cortical secretion, but rapidly rising blood sugar content also stimulates the adrenal cortex. It may be assumed that, when the blood sugar fluctuates widely, the adrenal cortical secretory functions also fluctuate greatly. The authors have felt that diabetic patients with vascular disease might benefit by stabilization of their adrenal cortical functions. Since this cannot be accomplished by medical means, bilateral total adrenalectomy followed by constant maintenance doses of the vital adrenal cortical steroids was attempted. Seven diabetic patients were studied before and after bilateral adrenalectomy. After baseline studies and regulation of the diabetes, all patients were prepared with 300 mg. of cortisone acetate for three days prior to surgery, and no vascular collapse or shock resulted during or after operation. After the surgical intervention the cortisone dose was gradually reduced. The results obtained suggest that vascular deterioration of the type seen in diabetes may involve abnormal adrenal cortical function. "Brittleness" and increasing insulin requirements point to functional impairment of the adrenals. If adrenalectomy is to be successful, it should be done fairly early in the arteriolar degenerative processes. There is evidence that it is a practical and hopeful therapy in properly selected patients.

The Results of Ureteral Transplantation to a Rectosigmoidal Pouch. W. F. Melick and J. J. Naryka. J. Urol. **73**:47-58 (July) 1955 [Baltimore].

Melick and Naryka combine ureteral transplantation into a rectosigmoidal pouch and proximal colostomy in an effort to produce a fecal-free urinary reservoir as a substitute for the bladder. Melick had participated in a preliminary report on this method. In this paper the authors present the histories of six patients in whom they employed the method successfully. It proved to have the following advantages: urinary continence is preserved by utilizing the rectal sphincter; urinary obstruction and infection are eliminated by the diversion of the fecal stream; and the danger of fecal fistula has been eliminated. Technically the procedure is easier than in other described "surgical artificial bladders" and more quickly performed, which should result in a lower operative mortality. Hyperchloremic acidosis has been no problem except in one patient in whom there was a preexisting chronic pyelonephritis and when there is incomplete emptying of the rectosigmoid. The only disadvantage is that the patient does have a colostomy that requires specialized daily care. The authors feel that from the esthetic point of view, one might question whether it is better to have a colostomy with urinary control or fecal control with a Rutzen bag constantly collecting urine. Both groups of patients have to make adjustments and concessions to their altered physiology and many in each group have done so and returned to their jobs.

Methods for the Elimination of Errors in Serum Acid Phosphatase Determinations. M. B. Ozar, C. A. Isaac and W. L. Valk. J. Urol. **74**:150-157 (July) 1955 [Baltimore].

The authors show that, since the introduction of serum acid phosphatase determinations in 1938 by Gutman and Gutman, much has been written as to the specificity and value of the tests. Many modifications in the technique of determining acid phosphatase have been made in an attempt to improve the accuracy and specificity of the procedure. Initially, urologists felt that they had a laboratory test that when positive was pathognomonic of metastatic carcinoma of the prostate. When reports appeared in the literature of elevated serum acid phosphatases in the absence of carcinoma of the prostate, many clinicians became disillusioned and some lost complete faith in this very valuable procedure. Reviewing the factors leading to erroneous results in acid phosphatase determinations, the authors found that hemolysis, previous endocrine or roentgen therapy, time and temperature, prostatic manipulation, certain electrolytes, spontaneous hydrolysis of the substrate, extraneous sources of acid phosphatase, human error, and the age of the patient should be considered in evaluating the significance of serum acid phosphatase levels. Available corrective measures are discussed. Approximately 10% false positive tests were obtained in patients with benign prostatic hypertrophy when total serum acid phosphatase values were interpreted. Only 2% false positive reactions were elicited in the same group of patients with benign prostatic hypertrophy when L-tartrate-inhibited "prostatic" serum acid phosphatase levels were used as an index. Patients with untreated carcinoma of the prostate and skeletal metastases uniformly showed elevated total as well as "prostatic" serum acid phosphatase values. In patients with carcinoma of the prostate previously treated, an elevated total or "prostatic" serum acid phosphatase is significant and usually indicates relapse. The nonspecific nature of L-tartrate inhibition of serum acid phosphatase was again demonstrated by its effect on the serum acid phosphatase values of prepuberal males and females. The authors conclude that the serum acid phosphatase determination is a valuable aid in the management of carcinoma of the prostate if the possibilities of error are known.

Local Injections of Hydrocortisone as a New and Effective Treatment for Strictures of the Urethra and Meatus. C. D. Bonner, M. K. Lyons and D. Shields. New England J. Med. **253**:130-134 (July 28) 1955 [Boston].

Excellent results were obtained in 8 patients with urethral and 10 with meatal strictures treated with local injections of hydrocortisone and dilatation. The average number of injections needed was three, but good results were sometimes obtained with one or two. Only two patients required more than three. The hydrocortisone, in an aqueous suspension, was injected directly into the stricture at two clock positions, five and seven, or three and nine. No anesthesia was required in patients with meatal strictures, and the injections, for which a 2 cc. syringe and a 22 gauge needle were used, were given directly without the aid of urethroscopy. Local, spinal, or general anesthesia was used as required in the patients with strictures of the anterior and posterior urethra; the strictures were located and visualized through the McCarthy foroblique panendoscope; and the injection was given with an endoscopic needle passed through the panendoscope and inserted into the stricture under direct vision. The most important feature of this insertion was to get the needle well under the mucosa and into the tunica propria before the hydrocortisone was injected. The initial dose of 6.25 mg. of hydrocortisone injected into each of the two sites chosen was later increased to 12.5 mg., and the number of injections, as well as the interval between them, was varied to suit the individual case. All the patients received prophylactic chemotherapy during cortisone administration. The success of the treatment did not appear to depend on the duration of the stricture, since a definite change, consisting of softening and easy distensibility, occurred in every case after the first injection, subsequently progressing to the point where no stricture could be felt. These results have been maintained for from 4 to 14 months without change in the clinical picture. The treatment described therefore seems to meet the requirements of an effective regimen for the control of meatal and urethral strictures. It is simple and relatively inexpensive, can be completed in a short time, and has so far proved completely effective. Its applicability to other genitourinary conditions is now under investigation.

Contribution to the Functional Study of Myelomatous Nephropathy. B. Magnani and V. Bonomini. Gior. clin. med. **36**: 557-571 (May) 1955 (In Italian) [Bologna, Italy].

Marked alterations of the kidneys are seen quite often in patients with myelomatosis. The clinical elements that might suggest an eventual renal impairment are, however, mild when they are not absent. Bence-Jones proteinuria is not by itself an index of the impairment of the glomerular filter because the Bence-Jones protein is so small in size that it escapes readily through the membrane of the glomerular capillaries. The renal functional damage varies in patients with myelomatosis according to the phase of the condition. As a consequence of the dysproteinemia, there may be an early alteration of the glomerular membrane with a secondary abnormal filtration of protein micelles and their passage into the tubular sections. In this phase the azotemia and the power of concentration are still within normal limits and the values of clearances are not significantly depressed. Later there is damage to the tubular cells, presumably because of phenomena of protein thesaurosis. The Volhard tests are altered and functional tests reveal a deficiency of the tubular section (reduction of the maximum tubular excretory capacity), which is greater than the concurrent reduction of the glomerular filtrate volume and the renal plasma flow. Thereafter, albumin-like masses in the lumen of the tubules cause the functional exclusion of the entire kidney. When more than two-thirds of the parenchyma is impaired, a condition of unmistaken renal insufficiency sets in. The functional tests are in this phase markedly depressed with an over-all reduction of the glomerular filtrate volume, the renal plasma flow, and the maximum tubular excretory capacity. The circulatory and tubular impairment is generally greater than the glomerular damage. The authors performed renal functional tests on three patients with myelomatosis. The results indicated a marked depression of the various test values in the following sequence: renal blood flow, renal plasma flow, maximum tubular excretion of *p*-aminohippuric acid, and, last, glomerular filtrate volume.

THERAPEUTICS

Chronic Bromide Intoxication. F. Norheim. Tidsskr. norske lægefor. 75:454-456 (June 15) 1955 (In Norwegian) [Oslo, Norway].

Patients with severe bromide intoxication often present such marked psychic symptoms that they are admitted in psychiatric departments. Milder cases may be overlooked. Not all physicians are attentive to the dangers in long-continued bromide treatment and to the symptoms in chronic bromide intoxication. Diagnosis can be made in vague cases, if the possibility of bromide intoxication is borne in mind. The sedative effect of bromides is good. Danger of habituation is slight, but all who prescribe bromides must be alive to the handicaps and dangers associated with their prolonged use. Bromides should not be prescribed in large amounts or with many reiterations. If it becomes necessary to give bromides for more than a relatively short time, the patient should be kept under close medical supervision. Special care is called for in the use of bromides for patients on salt-free diet, patients with impaired renal function, and older and asthenic patients. Four cases of chronic bromide intoxication are reported.

Influence of Alcohol as Contraindication Against Morphine. O. Naalsund. Tidsskr. norske lægefor. **75**:489-492 (July 1) 1955 (In Norwegian) [Oslo, Norway].

Two cases of acute morphine intoxication in chronic alcoholics, one case fatal, are reported mainly to illustrate the violent symptoms that, because of the synergism between alcohol and morphine-scopolamine, can occur on the use of morphine in therapeutically allowable doses in patients affected by alcohol. Influence of alcohol must be considered an absolute contraindication for the use of morphine. The symptomatology in acute morphine intoxication is seen in the first case: deep coma; insufficient or suspended respiration with periods of apnea, sometimes of Cheyne-Stokes type; and marked cyanosis with miosis. The combination of cyanosis and miosis is stressed as helpful in differential diagnosis. Since the introduction of N-allylnormorphine as a specific antidote in acute morphine intoxication, it is especially important to have the symptomatology in mind so that diagnosis can be made as soon as possible and treatment started. In the first case a condition threatening life was entirely changed in about a minute by the intravenous injection of N-allylnormorphine hydrobromide (Lethidrone).

Comparison of Two Regimes for the Treatment of Enterobiasis with Piperazine Citrate. R. W. Sappenfield, C. Swartzwelder, J. H. Miller and F. Martinez. J. Louisiana M. Soc. **107**:276-278 (July) 1955 [New Orleans].

The object of this study was to ascertain the efficacy of piperazine citrate for the treatment of patients with pinworm infection through a comparison of two schedules of therapy. The usual dosage schedule employed consists of anthelmintic therapy for two alternate weeks (treatment for seven days, rest seven days, treatment for seven days). The fact that some investigators observed that eggs of Enterobius vermicularis were demonstrable in Scotch tape anal swabs, taken on some patients during the seven day rest period, seems to indicate that autoinfection may occur during treatment with this regime. In the present study this schedule of therapy was compared with a straight 14 day course of medication. The daily dosage in both groups of patients was computed on a basis of 30 to 35 mg. per pound of body weight, up to a maximum of 2 gm., and was divided in two equal doses. Enterobius vermicularis was eliminated in 30 of 33 patients treated for 14 consecutive days with piperazine citrate and in 26 of 27 patients in whom the same anthelmintic was given with a treatment-free interval of one week intervening between the two weeks in which the drug was given. The authors feel that the difference between the therapeutic results with these two regimes is not statistically significant. Complaints during therapy were infrequent and mild in both groups of patients. Treatment for 14 consecutive days offers some practical and theoretical advantages over therapy for two alternate weeks.

Jaundice After Discontinuance of Chlorpromazine. G. C. Kohl, F. R. Maddison and R. E. Davis. Northwest Med. **54**:716-718 (July) 1955 [Seattle, Wash.].

Reviewing the literature for cases of jaundice occurring after cessation of chlorpromazine therapy, the authors found three papers that indicate a total of four cases in patients in whom jaundice developed after the drug had been discontinued. Duration of the jaundice in these patients varied from a transient day or two to several months. An additional case is described in a 54-year-old obese woman with refractory vertigo, nausea, and vomiting, who received treatment with chlorpromazine for 16 days in doses varying from 25 mg. given intramuscularly four times daily to 25 mg. given intramuscularly two times daily or given orally two times daily. Jaundice developed five days after the drug had been discontinued. Jaundice subsided after a duration of 32 days. The patient had been asymptomatic for four and a half months at the writing of the authors' paper. For the diagnosis of jaundice caused by chlorpromazine, which mimics closely, laboratory-wise and often clinically, obstructive jaundice and, therefore, requires differentiation from a surgically correctible jaundice, the following possible aids are offered: (1) a high index of suspicion; (2) current, or previous, administration of chlorpromazine; (3) jaundice occurring with laboratory findings suggestive of the obstructive type of jaundice, and (4) transient peripheral eosinophilia, which has not always been reported but was present in the authors' patient. In the final analysis the correct diagnosis will depend, as it always does, on careful evaluation of the total clinical picture.

Drug Evaluation in Angina Pectoris: Khellin, Heparin, Peritrate. R. C. Kory, A. S. Townes, R. E. Mabe and others. Am. Heart J. **50**:308-321 (Aug.) 1955 [St. Louis].

Three drugs, 5,8-dimethoxy-2-methyl-6,7-furanochromone (Khellin, Visammin), heparin sodium, and pentaerythritol (Peritrate) tetranitrate were given a therapeutic trial in 18 men between the ages of 33 and 76 years with a typical history of angina pectoris of from two months' to 12 years' duration. All of the patients had arteriosclerotic heart disease, six were hypertensive, and one patient had syphilitic aortic insufficiency. All patients were hospitalized. Subjective evaluation of the efficacy of the drugs was carried out in each patient by a daily record of each anginal attack throughout the study period. This was supplemented by objective evaluation with the anoxemia test. Six patients were tested with Khellin. In these patients the initial anoxemia test was followed by a two-week period on an identically appearing oral placebo, which in turn was followed by a second anoxemia test. Then after two weeks on 50 mg. Khellin given three times daily, a third anoxemia test was done. Of the six patients, five had positive results of the anoxemia test after Khellin administration or reverted to negativity after the placebo period. One patient reverted to negativity after Khellin administration but did not show any subjective improvement. One of the five patients with a persistent strongly positive response to the anoxemia test had a striking and sustained subjective improvement after Khellin administration. Khellin, though of definite therapeutic value in a limited number of patients with angina pectoris, is not generally useful because of the high incidence of side-reactions. Fifty milligrams of heparin given daily to 11 of the 18 patients produced subjective and objective benefit in only one, and this benefit was not sustained. This drug appears virtually ineffective in angina pectoris. Pentaerythritol tetranitrate in doses of 60 and 90 mg. daily provided impressive and sustained subjective improvement in two of six patients but failed to alter the patients' positive response to the anoxemia test. Although the general usefulness of therapeutic agents in angina pectoris can best be established by statistical compilation of "double blind placebo" subjective data as described by Greiner and co-workers [*J. A. M. A.* **144**:1025 (Nov. 18) 1950] and by objective testing, the therapeutic value in an individual patient may be amply demonstrated by alternate long periods on drug and placebo with a favorable response after the administration of the drug and failure of response after administration of the placebo. Since angina pectoris itself may vary greatly from patient to patient, it seems quite plausible that a drug might be quite effective in a limited number of patients but when averaged over a whole series of patients might appear ineffective. It would seem, therefore, that certain drugs, though of little general usefulness in angina pectoris, may be highly effective in an occasional patient.

Combination of Serpasil and Doriden in Treatment of Pain of Chronic Peripheral Arteriopathies and in Preoperative and Postoperative Sedation. D. Noceti and A. G. Nasta. Gazz. med. ital. **114**:82-85 (April) 1955 (In Italian) [Milan, Italy].

Serpasil and Doriden, a nonbarbiturate, hypnotic sedative, were given to 10 patients with chronic peripheral arterial disease and to 10 in the preoperative and 10 in the postoperative course to study the action of the combined administration on pain in the first group, its sedative and preanesthetic action in the second, and its sedative and calming action in the third. From a minimum of 0.25 mg. of Serpasil and 500 mg. of Doriden to a maximum of 0.75 mg. of Serpasil and 1.5 gm. of Doriden was given daily to the patients of the first group for 2 to 50 days. Those of the second and third group were given during the 48 hours preceding and following surgery, respectively, 0.75 mg. of Serpasil and 1.5 gm. of Doriden. The results revealed a decisive action of the combined therapy in the patients with chronic peripheral arterial disease in whom pain was eliminated or notably decreased without resort to morphine and its derivatives. Anxiety was greatly decreased in the patients who received the combined therapy preoperatively, and the patients who received it postoperatively were benefited by its analgesic and sedative action. Relatively large doses of the drugs were given without causing intolerance or side-effects. The authors conclude that this combined therapy should be considered an analgesic and sedative for the pain of chronic arterial disease in general, a preanesthetic means, and an excellent adjuvant in the therapy of painful states of the postoperative period.

Chloroquine Therapy in Rheumatoid Arthritis. R. E. Rinehart. Northwest Med. **54**:713-715 (July) 1955 [Seattle, Wash.].

The high incidence of amebiasis in patients with rheumatoid arthritis, which was reported by the author in a previous paper, suggested that an aggravating, if not causal, relationship between the two conditions might exist in some patients. Consequently, combined treatment with two highly effective amebicides, chloroquine phosphate and diiodohydroxyquin (Diodoquin), was given a trial in several hundred patients with rheumatoid arthritis. The dose employed was 0.65 gm. of diiodohydroxyquin given three times a day and 0.25 gm. of chloroquine given two times a day for from 3 to 12 weeks. Appreciable antirheumatic effects were being manifested with a minimum of toxic reactions and side-reactions when these drugs were administered in combinations. Further observations revealed that most of the antirheumatic effects, and most of the side-reactions, were caused by chloroquine. The most remarkable effects of the administration of chloroquine in rheumatoid arthritis were noted in children and young adults. Eight of 11 patients between the ages of 3 and 22 years with rheumatoid arthritis obtained major improvement or had a complete remission of the rheumatoid state when treated with amebicides. Eight of 14 patients between the ages of 38 and 72 years with rheumatoid arthritis obtained a lesser degree of over-all improvement with similar treatment. Actually, because of the age and disability of these patients, the improvement was more striking than in the younger group. A therapeutic trial with chloroquine is indicated for all patients with rheumatoid arthritis. Despite the high incidence of amebic infection in patients with rheumatoid arthritis and the pronounced improvement in the arthritis that followed amebicidal therapy, a causal relationship in individual cases was not proved. Years of experience on a much larger scale will be necessary to determine the exact relationship.

Local Use of Hydrocortisone Acetate in Orthopedic Conditions. M. Makin and T. Wiznitzer. Harefuah 48:253-255 (June 15) 1955 (In Hebrew with English and French summaries) [Jerusalem-Tel Aviv, Israel].

Nineteen patients with active rheumatoid arthritis were given 41 intra-articular injections of hydrocortisone acetate. This drug exerts a nonspecific local anti-inflammatory effect, inhibiting tissue reaction to noxious stimuli. A reduction of local pain, diminution of local inflammatory reaction, and increased range of motion suggested marked improvement of the condition in all these patients. Intra-articular injections of hydrocortisone are indicated in rheumatoid arthritis (1) before the correction by manipulation, stretching, or physiotherapeutic measures in patients with joint contractures; (2) when only one or two major joints are affected; and (3) in patients in whom general specific therapy with corticotropin (ACTH) and cortisone is contraindicated because of untoward reactions to the general therapy, associated complications such as hypertension or diabetes, and unsatisfactory response to general therapy. A total of 152 intra-articular injections was given to 103 patients with monoarticular osteoarthritis. Most of these patients had degenerative osteoarthritis of the knee joint. Ninety-six (93%) of these patients showed pronounced improvement of their condition for several weeks; improvement continued for several months in two patients. Hydrocortisone exerts only a temporary effect on the arthritic process, and its use is mainly indicated to abort acute exacerbations and to quiet the activity of the disease process. Thirty-two patients with stenosing tenovaginitis (Quervain's disease and trigger finger) were treated with local hydrocortisone that was injected into the involved area. Twenty-seven of these patients were cured within a brief period, most of them by a single injection of 25 mg. Local hydrocortisone injections were used also in isolated cases of gouty arthritis, tennis elbow, and frozen shoulder with varying success.

Hypertension Treatment with Alkaloids of Veratrum Viride and Veratrum Album Alone or in Combination with Hexamethonium Salts. D. Brunner, S. Altmann and L. Schindel. Acta med. scandinav. 151:487-498 (No. 6) 1955 (In English) [Stockholm, Sweden].

Of 87 patients with hypertension who were treated with simple psychotherapy, salt-poor diet, rice diet, and various hypotensive drugs at one of the medical departments of the Government Hospital in Jaffa, Israel, 55 were treated with the alkaloids derived from Veratrum viride in the form of alkavervir (Veriloid) or Veradine (an Israeli proprietary preparation) and with the alkaloids derived from Veratrum album in the form of Protoveradine, an Israeli proprietary preparation of protoveratrine. Of the 55 patients, 49 were followed for from three months to two years. Thirty-one patients received Veratrum preparations alone with good results, and 24 required additional oral administration of hexamethonium. This combined treatment made it possible to use smaller doses of each of the drugs (12 to 14 mg. of Veriloid or Veradine, or 3 to 4 mg. of Protoveradine daily, and not more than 2,000 mg. of hexamethonium daily); thus undesirable side-effects could be prevented and parenteral administration avoided. Results were good in 39 patients and fair in 16. Eleven patients did not respond to this nor to any other method of treatment. Results were evaluated according to the level of the blood pressure when the patient resumed his work and not according to that during rest. Of four illustrative cases reported on in detail, one was a 66-year-old woman with malignant hypertension associated with macroscopic hematuria, renal failure, and papilledema who was treated with protoveratrine alone, and one was a 49-year-old man with hypertension of 10 years' duration and serious hypertensive encephalopathy who was mentally disturbed and was treated with protoveratrine and hexamethonium bromide. The woman showed a good response to protoveratrine; the papilledema and the hemorrhages of the fundi disappeared, and the level of the blood urea was restored to normal. The mental state of the man improved, the blood pressure was reduced from 230/120 mm. Hg to 180/110 mm. Hg, and he was able to work in an office. Although both patients had severe dyspeptic disturbances shortly after treatment with protoveratrine was started, they got accustomed to the drug. Protoveratrine is a powerful hypotensive agent that may cause various undesirable side-effects. It does not, however, influence kidney function and this may be used in cases of renal failure. Fair results may be obtained with this drug even in patients with malignant hypertension.

Results of French Experiments with Prednisone (Metacortandracin) in Inflammatory Rheumatism. F. Coste, F. Delbarre, P. Massias and others. Rev. du rhum. 22:385-405 (May) 1955 (In French) [Paris, France].

French experimentation to date with the new dehydrocortisone, prednisone, formerly metacortandracin (Δ1,4-pregnadiene-17α, 21-diol-3, 11, 20-trione), a synthetic steroid, is based on 75 patients treated for from 15 days to two months. Their diagnoses were as follows: rheumatismal polyarthritis, 61; ankylosing spondylarthritis, 4; monoarticular or oligoarticular rheumatism, 2; gout, 2; tendinous synovitis, 2; scapulohumeral periarthritis, 2; painful exostosis of the calcaneum, 1; and coxarthrosis, 1. Most of these patients had been receiving hormone therapy with orally administered cortisone or hydrocortisone. Dosage of the drug was from 30 to 40 mg. for from 5 to 10 days, after which the doses were diminished to the minimal effective dose, which varies from 15 to 25 mg. according to the patient. Rapid clinical improvement was seen, especially of pain, but also in swelling and rigidity. The sedimentation rate often underwent a spectacular fall. Prednisone proved to be twice as effective as orally administered hydrocortisone and three times as effective as cortisone. No important physiological modifications were observed in any patient as a result of treatment. Six complete failures occurred in four patients with chronic rheumatismal polyarthritis, in one with tendinous synovitis, and in one with coxarthrosis. Certain intolerance phenomena were seen despite the routine prescription of low-sodium diet and the frequent adjunction of nervous sedatives. There were nine cases of various kinds of edema, six cases of digestive disturbances, seven of nervous disorders, three of muscular cramps, two of skin reactions, and one of cardiac insufficiency. These occurred especially in response to the elevated doses of prednisone (35 to 40 mg.). Thus it seems that the new hormone requires the same precautions as the ones formerly used.

Hepatic Necrosis and Other Visceral Lesions Associated with Phenylbutazone Therapy. J. M. McCarthy and R. T. Jackson. Brit. M. J. 2:240-242 (July 23) 1955 [London, England].

The patient whose history is reported was a woman, aged 73, who was first seen on April 30, 1954, when she gave a history of mild rheumatic pains of many years' duration. On the previous day she awoke with severe pain and swelling of small joints of her right hand. This spread during the day to her right wrist and elbow, and on the morning of the 30th had started in the left metacarpophalangeal joints. As the arthritis was very acute and spreading rapidly she was given cortisone acetate orally, starting with a dose of 100 mg. a day; this was rapidly increased to 200 mg. with satisfactory results, her joints showing improvement. Reducing the dosage was followed by a return of the arthritic symptoms. From June 12 to 16 she was given three 200 mg. phenylbutazone tablets a day, a total of 20 tablets. This was to tide her over the symptoms due to the withdrawal of cortisone. She left hospital on July 2 on a maintenance daily dose of 50 mg. of cortisone. When readmitted on July 24, she stated that she had taken no cortisone since July 17, as she had noticed that her ankles and feet were swollen. Her joints were again painful and swollen. She was given phenylbutazone from Aug. 5 to 15, three 200 mg. tablets a day; total tablets, 33. On Aug. 15 the phenylbutazone was stopped, as examination revealed impaired resonance with weak breath sounds and numerous rales over the upper zone of the right lung and signs of an effusion at the left base. X-ray examination confirmed the presence of a pleural effusion. The woman died on Aug. 23. The histological findings at necropsy fell into three main categories: (1) necrotic parenchymatous lesions in the liver and kidneys; (2) granulomas in the epicardium, pericardium, and lungs; and (3) interstitial myocardial lesions. The hepatic and renal lesions were similar to those found in chemical poisoning, and in this instance they were almost certainly due to phenylbutazone administration. Necrosis of this degree in both organs has not previously been described as caused by phenylbutazone, although there have been reports of milder hepatic damage in other patients with rheumatoid arthritis receiving phenylbutazone. Pleural and epicardial granulomas were most probably modified rheumatoid nodules. Other pulmonary changes conformed to those found in acute rheumatic disease. The authors feel that the myocarditis and the necrosis in the liver, and possibly also in the kidney, were related to one another in so far as, with the development of the myocarditis, passive congestion supervened and the anoxia thus induced in the parenchymatous cells of the liver and kidney aided the development of necrosis by the toxic action of phenylbutazone.

Fatal Cases of Bismuth Intoxication. T. L. Sterne, C. Whitaker and C. H. Webb. J. Louisiana M. Soc. **107**:332-335 (Aug.) 1955 [New Orleans].

Within a two month period four children with acute gingivostomatitis were admitted to hospitals in Shreveport, La., because of complications arising from treatment with a single injection of a soluble bismuth compound. All four of these children, ranging in age from 13 months to 6 years, died. Autopsy was performed in three of the patients. At one time it was generally believed that acute gingivostomatitis ("trenchmouth") in children was caused by a fusospirochetal organism. Bismuth therapy was introduced on the supposition that it would be effective against this organism. Studies of Dodd and Buddingh proved, however, that this disease results from primary infection with the herpes virus, which is not affected by bismuth. The infection is self-limited and the child is benefited most by attention to hydration and nutrition. If secondary infection with spirochetal organisms or other bacteria occurs, penicillin or other antibiotic therapy is far safer and probably more effective than bismuth. The administration of soluble bismuth involves the danger of toxic effects on kidney and liver tissues. Experimental work with rabbits indicated that previously damaged kidneys were more susceptible to bismuth injury than normal kidneys. In this connection the authors point out that one of their group had noted in 1941 that some renal damage is associated with acute gingivostomatitis.

Megaloblastic Anaemia Due to Phenytoin Sodium. G. M. S. Ryan and J. W. B. Forshaw. Brit. M. J. **2**:242-243 (July 23) 1955 [London, England].

Ryan and Forshaw observed two patients with a megaloblastic anemia and normal gastric acidity who were on diphenylhydantoin (phenytoin) sodium therapy. Since the possibility that phenytoin sodium might produce a megaloblastic anemia had been suggested by others, the authors examined the blood of 102 epileptic patients who had been taking phenytoin sodium for several years, and the laboratory records of 140 patients with a hemoglobin value below 70% were also surveyed. None of the 102 epileptic patients had a megaloblastic anemia, but one possible case was discovered from the survey of the records. This case and the aforementioned two patients are described. The authors feel that, in view of the rarity of this condition and the excellent response to treatment, the use of this drug is not contraindicated. It is probably wiser, however, to change to another anticonvulsant drug in those patients in whom a megaloblastic anemia develops. Of the total of 10 patients whose cases have been described, 7 were treated initially with vitamin B_{12}, but only 4 showed a good response. On the other hand, there was a good response in the two patients treated with folic acid initially and in three patients who were given folic acid after vitamin B_{12} had failed.

Parenteral Chloramphenicol Therapy in Bronchial and Pulmonary Infections. R. Storti, N. Mocchi and E. Bonvini. Minerva med. **46**:1745-1749 (June 16) 1955 (In Italian) [Turin, Italy].

Chloramphenicol succinate in average daily doses of 2 gm. was given intramuscularly to seven patients with pulmonary abscess, to four with bronchopneumonia, to one with suppurative bronchiectasis, to one with typhoid bronchopneumonia associated with secondary empyema, and to one with diffuse bronchitis. Some patients received the drug also by the intravenous and intracavitary routes or in aerosol form. Fever subsided in the patients with bronchopneumonia in three days and in those with pulmonary abscess and suppurative bronchiectasis in seven days. The last-named patients continued to receive the drug for varying periods, sometimes for as long as 46 days after the fever had subsided. Although the good effect of the therapy became evident sooner in the patients with bronchopneumonia, the best results were obtained in those with pulmonary abscess in whom anergy and poor general condition were extremely marked before the therapy was started. Chloramphenicol succinate had a marked antibiotic activity also in cases that had been resistant to other antibiotics. It was especially effective when given intravenously. Intolerance, side-effects, or changes in the blood picture were not observed. There was a mild and transitory leukopenia and anemia induced by the action of the drug in three patients during the treatment period.

PATHOLOGY

Anatomic Lesions Observed in Infants Dead of Toxicosis. J. Chaptal, R. Jean and R. Loubatières. Semaine hôp. Paris **31**: 2473-2480 (July 10-14) 1955 (In French) [Paris, France].

Necropsies were performed in 15 infants dying of toxicosis. Three of these died several hours after treatment had been initiated and the rest in from two to six days after being hospitalized. The deaths all occurred before the authors had found what metabolic disturbances are responsible for the complications of toxicosis and, therefore, before the period in which these patients received the treatment of choice for their disease. The lesions found in the different patients resembled each other in that they represented the ultimate stages of suffering from a common cause. Other authors have insisted on the importance of vascular changes in the pathology of toxicosis, but these workers found that vascular lesions were neither the most frequent nor the most severe. The most striking lesions were those seen in the most active parenchymal cells. They were often associated with an irritative syndrome of the connective and reticuloendothelial tissues. These alterations are caused by the deranged metabolism of each cell, which is in turn the result of the general imbalance of the interior environment characteristic of toxicosis. It can therefore be said that there are no specific lesions of toxicosis. The changes observed represent nothing more than the consequences of prolonged hydrosaline imbalance and its effects on general body metabolism.

INDUSTRIAL MEDICINE

Solvent Hazards in the Dry-Cleaning Industry. R. G. Bourne. M. J. Australia **1**:879-881 (June 11) 1955 [Sydney, Australia].

There are two hazards associated with the solvents used in dry cleaning—contact dermatitis and inhalation effects. Medically speaking, the solvents fall into two main classes: petroleum derivatives and chlorinated hydrocarbons. The petroleum derivatives used include the following: white spirit, composed of mixed hydrocarbons—boiling point, 150 to 210 C; Stoddart's solvent, composed of mixed hydrocarbons—boiling point, 300 to 400 C; and cleaners' naphtha. The maximum allowable concentration is 1000 parts per million of air for each. White spirit is the dry-cleaning agent most widely used. It is superior to the chlorinated hydrocarbons for the following reasons: (1) it vaporizes less readily; (2) it has a lower toxicity; and (3) it costs much less. Because of factors (1) and (2) and provided reasonable precautions are taken, the likelihood of systemic effects due to inhalation of vapor is almost nil with white spirit. The author had no opportunity of observing the chlorinated hydrocarbons in use. The most important factor in the prevention of harmful effects from white spirit is to avoid contact of the solvent with the operator's skin. The author suggests that suitable machinery would not only prevent dermatitis but would save time and money. The use of gloves involves the disadvantage that they are expensive and cause discomfort. Barrier creams are of value. In diagnosing dermatitis from dry-cleaning solvents, it should be determined that the patient actually handles the solvent, that the lesion has appeared since he handled it, and that the condition is relieved when he is away from work. Pustular dermatitis is most common. Small pustules are found around the hair follicles of the hands and forearms. Vesicles may occur and may become purulent. Maceration of the skin is caused by the removal of fat by the solvents, followed by secondary infection. Boils and carbuncles may develop. Occasionally the skin is fissured as well as dry. Total removal from contact with the solvent is the only means of complete cure. In spotting, the process by which stains are removed, many potentially dangerous volatile materials, such as carbon tetrachloride, benzol, and carbon bisulfide are used. The damage to liver and kidney caused by exposure to chlorinated hydrocarbons is briefly mentioned. Total removal from exposure and adequate treatment are essential, because such exposure can be fatal.

Allergic Reactions to Penicillin in Workers in Charge of the Antibiotic's Production. R. Maffei and L. Napolitano. Minerva med. 46:1785-1792 (June 20) 1955 (In Italian) [Turin, Italy].

Of the 156 workers (127 women) in a penicillin factory who came in contact with the finished product, 19 (12.17%) showed allergic manifestations. These were definitely the result of allergic hypersensitivity to the antibiotic in all except four workers with dermatitis who had previously had penicillin therapy. The fact that these reactions followed the workers' exposure to the antibiotic was proved by the results of (1) the scratch test with powder penicillin diluted in one drop of isotonic sodium chloride solution, (2) the intracutaneous test with 0.05 cc. of a penicillin solution containing 2,000 units of the antibiotic per cubic centimeter, and (3) the patch test with a penicillin solution containing 10,000 units of the antibiotic per cubic centimeter. Of the three tests, the intracutaneous was the most valuable. Asthma was found in 3 workers, allergic dermatitis in 14, and Quincke's angioneurotic edema in 2. The three cases of asthma are noteworthy in that they point to the possibility of sensitization by inhalation. The authors emphasize a grave danger to workers in the penicillin industry: it is possible that a sensitization acquired by occupational contact may cause, after the eventual administration of the antibiotic, a severe reaction of the anaphylactic type. This danger is much greater if the person is unaware of the possibility of having acquired a state of general hypersensitivity and the physician relies on the fact that the person never had penicillin therapy before. While the age of the workers in this series showed no relationship to the allergic manifestations, the time of exposure to the antibiotic, which was always of at least several months, did. A prophylactic measure of great value that should be introduced in penicillin industries is the systematic use of skin reaction tests. These will indicate whether the worker has already acquired a state of hypersensitivity, in which case he should be temporarily transferred to another department to avoid the eventual onset of allergic manifestations. The worker will also be made aware of the possible risks that the eventual administration of penicillin by the parenteral or any other route may involve. The authors suggest that the administration of antihistamines may be useful before penicillin is given to workers who have shown allergic reactions or whose skin reaction to the antibiotic is positive. The use of protective creams, rather than rubber gloves, for the hands is also suggested. A specific desensitizing therapy, especially in patients with chronic urticaria, bronchial asthma, and dermatitis, can be efficacious. When an immediate result is desired, corticotropin and cortisone may be administered first, and the desensitizing treatment later.

RADIOLOGY

Mucous Colon. M. H. Poppel, H. Adler, H. G. Jacobson and others. Radiology 65:50-56 (July) 1955 [Syracuse, N. Y.].

The syndrome of mucous colon, which consists essentially of diarrhea of varying degree with the passage of mucus, has many synonyms, such as mucous colitis, irritable colon, spastic colon, mucocatarrhal colitis, and chronic catarrhal colitis. The term mucous colon is used to provide a clear distinction between this syndrome and any form of actual inflammation, such as ulcerative colitis to which it bears no relation. Abdominal pain, occasional vomiting, fulness, and belching are often associated with the diarrhea, and other signs and symptoms, such as chest pain, palpitations, sweating, dizziness, headache, and tremor, may also be present. The physical findings may consist of tenderness in the region of the descending colon and a firm, palpable, tube-like descending colonic segment in a thin patient. The general condition is good. Most of the patients apparently have a labile autonomic nervous system with concomitant cardiovascular instability, and the present-day tendency is to regard the syndrome of mucous colon as a somatic response to nervous tensions, e. g., fear, anxiety, and resentment. The roentgenologist is in a position to establish the diagnosis of mucous colon if he is properly aware of its clinical and radiological features. Roentgenologic examination shows no abnormal structural changes, but functional abnormalities are sometimes found. These abnormalities, which may be the result of the peculiar mucoid material in the colon, spasticity, or peristaltic effect, may also be seen when barium is administered orally. The mucus content of the colon is manifested by radiolucent defects in the barium column, and postevacuation films may show thickened mucosa with distorted folds. Ulcerative colitis has not developed in any of the 17 patients in whom a diagnosis of mucous colon was established by the authors, although they have been followed for periods of as much as eight years.

Gastric Adenomyosis vs. Aberrant Pancreas. C. V. Cimmino. Radiology 65:73-77 (July) 1955 [Syracuse, N. Y.].

Gastric adenomyosis, or adenomyoma, consists of a nodule, usually within 5 or 6 cm. of the pyloric ring, the thickening being palpable from the exterior of the stomach, with bulging of the peritoneal surface and with intact overlying mucosa. The small mass is found on gross section to protrude into the lumen of the stomach, and the lesion is seen to be mainly submucosal, although the entire wall may be involved. Pinpoint cystic cavities may be seen. The glandular structures may be differentiated from the muscular component by their lobulation and yellowish color. The naming of the microscopic stages, which range from those with undifferentiated columnar epithelial structures, exclusively, through those with good amounts of both undifferentiated and differentiated acinar tissue to those with a cellular pattern indistinguishable from normal pancreas, the so-called aberrant pancreas, or even normal entopic Brunner's glands, has occasioned some confusion in the past. Stages in which the epithelial components consist almost exclusively of undifferentiated acinar tissue have, with some variations, been called adenomyosis; those in which there was differentiated tissue comprising pancreas alone have been designated aberrant pancreas; and those in which Brunner's glands are the sole element are known as heterotopic Brunner's glands. The term adenomyosis, though variously used, has apparently never been applied to the stage designated as aberrant pancreas. Study of a patient in whom a growth diagnosed radiologically before operation as aberrant pancreas in the stomach proved on pathological examination to be adenomyosis suggests that the specific term aberrant pancreas should be abandoned by radiologists in favor of the generic term adenomyosis. The fact that no significant clinical or radiological differences could be found in this case—the only one of its kind recorded—by which the tumor could be distinguished preoperatively from typical aberrant pancreas makes it seem advisable to leave the diagnosis of the specific differentiation to the pathologist. Increasing familiarity on the part of radiologists with the generic concept of adenomyosis in the stomach (and elsewhere in the digestive tract) and the confidence with which they present their diagnosis will prevent many unnecessary gastrectomies.

Gastroduodenal Intussusception. H. Mauthe and G. Zwicky. Radiology 65:86-89 (July) 1955 [Syracuse, N. Y.].

Gastroduodenal intussusception appears in roentgenograms as a large, well-circumscribed filling defect in the duodenum surrounded by streaks of contrast material trapped in the folds of the duodenal mucosa. These streaks tend to arrange themselves in a circular or bed-spring pattern almost identical with that seen in the case of an ileocecal intussusception. A large polypoid lesion originating in the duodenum may also produce a similar appearance, but the shortening and distortion of the distal end of the stomach that accompanies gastroduodenal intussusception makes it possible to differentiate between these two conditions. Ileocecal and gastroduodenal intussusceptions in adults apparently occur when a neoplasm on the wall of the stomach or bowel drags the wall with it as it is propelled forward by peristaltic action. Very few cases of gastroduodenal intussusception have been reported and in only four, including two seen by the authors within a period of four months, was the condition diagnosed before operation. The intussusception, diagnosed by roentgen examination in each of the authors' cases, was found at operation to have been caused in one by a gastric lipoma and in the other by a polypoid adenocarcinoma. The fact that gastric lipomas are rare, only 103 having been found by Palmer when he reviewed the literature in 1951, gives a special interest to the first of these two cases.

PHYSIOLOGY

The Physiologic Closure of the Ductus Arteriosus in the Newborn Infant. F. L. Eldridge and H. N. Hultgren. J. Clin. Invest. 34:987-996 (July) 1955 [New York].

The exact time of functional closure of the ductus arteriosus in the newborn human infant is still unsettled, but there is evidence that, at least in some infants, the ductus may be patent during the first few hours of life and that it may be the site of a venoarterial shunt of considerable magnitude. The present study was stimulated by the observation that infants in the neonatal period occasionally show cyanosis of the lower part of the body but not of the upper portion. Regional cyanosis of this type has been observed in older children and adults who have a patent ductus arteriosus with pulmonary hypertension and a venoarterial or reversed shunt through the ductus. Owing to this shunt of venous blood through the ductus to the descending aorta, the arterial oxygen saturation is lower in the feet than in the hands. The authors believed that, if a similar shunt were present in the newborn infant, it would continue as long as the ductus remained patent and the pressure in the pulmonary artery exceeded that in the aorta. The authors determined the oxygen saturations of blood samples obtained from the hand and foot of 60 infants from 40 minutes to 11 months after birth. It was found that, in a majority of infants under 3 hours of age, and in many infants under 3 days of age, the foot saturations were significantly lower than hand saturations. Hypoxia increased or reestablished the hand-foot oxygen saturation difference in infants up to 15 hours of age who had minimal initial hand-foot differences. The following implications have been drawn from these studies. 1. The ductus arteriosus may be open in the newborn human infant. 2. Under these circumstances it is the site of a venoarterial shunt of considerable magnitude that persists in a significant number of infants up to 72 hours of life. 3. A high pulmonary artery pressure is present at birth and persists as long as the venoarterial ductal shunt exists. 4. The cessation of the venoarterial ductal shunt is probably due to a fall in pulmonary artery pressure below the pressure in the aorta, rather than to an actual closure of the ductus. 5. Studies of blood gases in newborn infants in which heel blood has been used are not representative of true arterial blood, since an admixture of venous blood from the ductus may be present. 6. Heart murmurs are rarely heard in the newborn infant, in spite of the early physiological patency of the ductus arteriosus.

Smears from the Oral Mucosa in the Detection of Chromosomal Sex. K. L. Moore and M. L. Barr. Lancet 2:57-58 (July 9) 1955 [London, England].

The skin biopsy test of chromosomal sex is being used with increasing frequency as an aid to differential diagnosis in errors of sex development, such as hermaphroditism and gonadal dysgenesis. In the experience of Moore and Barr it is reliable only if the sections are of good technical quality. Difficulty is sometimes encountered in obtaining sections that display fine nuclear detail. The authors investigated smears from the oral mucosa in the hope of simplifying the cytological detection of chromosomal sex. In 140 subjects (81 males and 59 females) the mucosa of the cheek was rubbed firmly with the edge of a wooden tongue depressor. The material obtained was smeared gently on microscopic slides that had been coated with a thin film of Mayer's egg albumin. Thirteen of the smears were from infants aged 2 to 7 days; the ages of the other subjects ranged from 2 months to 62 years. The Ayre spatula was a useful substitute for a tongue depressor when dealing with infants. The slides were immersed immediately in Papanicolaou's fixative (equal parts 95% ethyl alcohol and ether). Drying of the smear was avoided. The period of fixation was not critical; times of from 2 to 24 hours were satisfactory. The fixed smears were passed through 70% alcohol, 50% alcohol, and distilled water, 5 minutes in each, with two changes of distilled water. The following staining procedure resulted in good nuclear detail: (1) staining in a 1% solution of cresyl echt violet (Coleman and Bell) for 5 minutes; (2) differentiation in 95% alcohol (two changes) for about 5 minutes; (3) further differentiation in absolute alcohol, checking at intervals with the microscope until the details of cell structure were sharply defined; (4) clearing in xylene (two changes); and (5) mounting in picolyte or neutral balsam. Some smears were stained by the Feulgen method for desoxyribose nucleic acid. The characteristic female sex chromatin was clearly visible in the epithelial cell nuclei of females, while a similar chromatin mass was not seen in the cells of males. The authors believe that, with reasonable care, chromosomal sex can be diagnosed from smears of oral mucosa with very little chance of error. The preparation of mucosal smears has the advantage of simplicity over skin biopsies.

Distribution and Absorption of Tobacco Tar in the Organs of the Respiratory Tract. P. Ermala and L. R. Holsti. Cancer 8:673-678 (July-Aug.) 1955 [Philadelphia].

The localization, concentration, and duration of action of chemical carcinogens are decisively influenced by their distribution and rate of absorption in the body. Study of the distribution and rate of absorption of tobacco tar in the respiratory tract of experimental animals by the fluorescence-microscope method and in a full-scale plaster model of the human organs showed a striking correlation between the clinical incidence of cancer and the localization of the tar. The heaviest localization, as shown on the model, generally occurred at the sites first reached by the smoke in its most concentrated form, such as the lips, the mobile portion of the tongue, and the mucosa of the cheeks between the rows of teeth. Localization farther down in the respiratory tract was heaviest in the narrow portions where the smoke stream strikes the walls of the organs, as at the tonsillar region, the vocal cords, and the tracheal and bronchial bifurcations. The hard palate and the trachea, on the other hand, show only very small amounts. Changes in the direction of the smoke stream produced by gyratory motions in the buccal cavity also keep it from bearing directly on the dorsal wall of the pharynx and settling there. Qualitative as well as quantitative differences related to the type of smoking (pipe, cigarette) were found in the tar localized in these various regions. Contact between the tar and the tissues, however, is only the starting point for the absorptive process, i. e., the penetration of the tar into the cells and tissues, which is due not so much to the amount of tar on the tissue surface as to the absorptive properties of the tissue itself. The absorption studies made on animals showed that the localization of the action of tobacco tar corresponds to the passive distribution observed in the plaster model with the exception of tissues containing submucous fat. These are the tissues that are capable of storing the carcinogenic agent and thus enabling it to exert the long and intensive local action necessary for cancer production. The correlation between the clinical incidence of cancer and the localization of the effect of tobacco tar revealed by these studies furnishes additional, though not conclusive, support for the theory that tobacco has some significance as a carcinogenic agent. The specific share of the chemical carcinogen cannot be distinguished from that of the chronic irritation of tobacco smoking, however, because they both become effective at the same sites.

BOOK REVIEWS

Symposium on Atherosclerosis. Held under auspices of Division of Medical Sciences, National Academy of Sciences, National Research Council, at request of Human Factors Division, Air Force Directorate of Research and Development, 22-23 March, 1954. Publication 338. Cloth. $2. Pp. 249, with illustrations. National Academy of Sciences—National Research Council, 2101 Constitution Ave., Washington 25, D. C., 1954.

This volume grew out of the interest of the Human Factors Division in the problem of cardiovascular disease as a factor limiting the length of service of flying personnel. As originally planned, the conference was to have dealt only with lipoproteins, but as finally constituted, the symposium extended well beyond this field and even considered problems other than atherogenesis. The 23 papers presented are given *in extenso* and are adequately illustrated. An exceptionally wide range of disciplines is represented. The papers are divided into five groups, and the contents of each group have been summarized by a group chairman. There is also a brief report of the discussion that followed each paper. The first part presents anatomic and pathological studies bearing on the pathogenesis of atherosclerosis, with extensive discussion of the reaction of the vessel wall to various types of injury. The contribution of the electron microscope to studies in this field was dealt with. Finally, a large part of the discussion covered the biochemical approach to the problem with special reference to lipid and lipoprotein metabolism. The caliber of the various presentations varies, but the symposium as a whole is excellent, bringing together as it does up-to-date views on the various aspects of atherogenesis.

A critical reader inevitably uncovers certain inconsistencies and defects, to which reference might be made. In Winternitz's discussion of the blood supply of the vessel wall (page 15), he states that, because cholesterol is synthesized by the organism, the problem of "the relationship of cholesterolemia to diet . . . has become less pressing." Few would agree with this statement. Hass, writing on vascular structure, states (page 30) "deposits of lipids . . . appear at about ten years of age in the intima of the human aorta. . . ." Surely, much earlier deposits have been demonstrated. Indeed, on page 34, Duff refers to the work of Fangman and Hellwig, who found lipid deposits in the coronary intimal cushions of newborn infants. Hass's statement (page 31) that "the amount of lipoprotein found was not related quantitatively to the level of plasma cholesterol" is not backed by references. Since essentially all plasma cholesterol exists as lipoprotein complexes, it is difficult to see the justification for this view. Dr. Albert Lansing's paper was marred by a deficient system of references. His reference to Chaikoff and Entenman (page 59), who, he states, "observed the existence of an antifatty liver factor which is protease free and is present in the pancreas" might be challenged. It is well known that choline is present in the pancreas and that methionine present in pancreatic protein exerts a lipotropic action. Chaikoff and Entenman are best known for their demonstration that the so-called lipocaic prepared from pancreas is lipotropic because of its proteolytic activity. Although Mann and Stare present a stimulating paper on nutrition and atherosclerosis, strong exception must be taken to their statement (page 172) that "it is difficult to see why the myth persists that vegetable fat behaves differently in the diet than does animal fat with respect to cholesterol metabolism. There is no good evidence to support this belief." This statement was as incorrect in March, 1954, as it is today.

This volume is an important addition to the literature in this broad and controversial field and can be recommended as essential reading to every serious student of this subject.

Autoradiography in Biology and Medicine. By George A. Boyd, Director, Arizona Research Laboratories, Phoenix. Cloth. $8.80. Pp. 399, with 98 illustrations. Academic Press, Inc., 125 E. 23rd St., New York 10, 1955.

Autoradiography is a production of an image on a photographic plate or film by radioactive radiation. The author has prepared a well-organized book that can be easily understood by the nonexpert in the field. Several techniques for producing various types of audiograms are discussed in detail. The bibliographic material consists of: (1) a bibliography covering most of the literature through 1953, (2) an author index, and (3) a classified subject index. The last designation will be of special interest to those interested in applying these techniques to specific branches of research, such as tissue, cancer, and bone and teeth studies and embryology. Methods for preparing nonflat surfaces, fluids, histological sections, cells, dust, and other microscopic particles are outlined. This authoritative book, containing a generous number of well-chosen illustrations, should be of interest to research workers in biology and medicine.

Breast Cancer and Its Diagnosis and Treatment. By Edward F. Lewison, B.S., M.D., F.A.C.S., Professor of Surgery, Johns Hopkins University School of Medicine, Baltimore. Cloth. $15. Pp. 478, with 181 illustrations. The Williams & Wilkins Company, Mt. Royal and Guilford Aves., Baltimore 2, 1955.

This is a comprehensive and well-written book that brings all aspects of cancer of the breast to the reader in a readable fashion. The anatomy, physiology, pathology, and experimental work are fully discussed. Major emphasis is placed on diagnosis, treatment, and prognosis. Reasonable criteria of operability are outlined. The author believes that the meticulous standard radical mastectomy provides the best prospect for permanent or protracted freedom from demonstrable disease in operable cases. The McWhirter plan of treatment, extended radical mastectomy, radiotherapy, and palliative hormone therapy are all presented with thoroughness and balanced judgment. The responsibilities of the surgeon, the psychological impact of cancer of the breast on the patient, and the important factors of after-care, including physical and psychological rehabilitation, are discussed with understanding. The contributors were chosen with care, and the sections written by them are excellent. The bibliographies are extensive and up-to-date, including some 1955 references. The illustrations are of good quality, and the statistical tables are clear and well designed. The book has value as a reference work for the undergraduate and the young physician. Its completeness and readability make it a contribution of importance to those experienced and well informed in the field of breast cancer. It should be a valuable addition to any private or institutional library.

Good Health for You, Your Family, and Your Community. By Nelson S. Walke, Ph.D., Professor and Chairman, Department of Health and Physical Education, Brooklyn College, New York, Nathan Doscher, LL.B., Ph.D., Assistant Professor, Department of Health and Physical Education, Brooklyn College, and Glenna Garratt Caddy, M.D., Supervising Psychiatrist, Brooklyn State Hospital, Brooklyn, N. Y. McGraw-Hill Series in Health Education, Physical Education, and Recreation. Clifford Lee Brownell, consulting editor. Cloth. $4.75. Pp. 415, with 48 illustrations. McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 36; 95 Farringdon St., London, E.C.4, England, 1955.

In a well-organized approach that emphasizes the varied factors operating to produce total health in the individual, the authors have done a good job of orientation for the college student reader. Logically, the volume begins by considering family life and health, goes next into community health, and ends with attention to personal health. The longest of the three sections is on community health, and this also is a logical procedure because of the great importance this phase of living has assumed. Control and prevention of communicable diseases are extensively described, and there are discussions of mental health problems, control of foods, drugs, and cosmetics, housing, accident prevention, first-aid and disaster measures, and school health. Because basic health aspects are considered in the first part, the part on personal health is pinpointed on special aspects, including weight control, vision and hearing, data on narcotics and stimulants (a part that is especially well done), personal

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

appearance, and rest and recreation. General health and medical care, dental health, diet, the effects of heredity, and preparation for family life are the main topics in part 1.

This volume presents a good roundup of available material in a frank, readable style. At the end of each chapter, problems based on material that has been presented are listed. In addition, each chapter has a bibliography under the unusual title of "interesting reading." The printing is clear, and a fine quality of paper is used. Numerous illustrations add to the attractiveness of the book, which can be highly recommended.

Elsevier's Encyclopædia of Organic Chemistry. Founded by (the late) E. Josephy and F. Radt. Editor in Chief: Dr. F. Radt. Series III: Carboisocyclic Condensed Compounds. Volume 14-supplement: Nor-Steroids. Steroids: Hydrocarbons, Halogen, Nitrogen, and Unsubstituted Monohydroxyl Compounds. Edited by A. Georg, with assistance of M. Georg-Plant. Cloth. $36 for set subscribers; $42 for subscribers to Series III; $48 per single copy. Pp. 1347s-1867s. Elsevier Press, Inc., 402 Lovett Blvd., Houston 6; 155 E. 82nd St., New York 28; 118 Spuistraat, Amsterdam C, Netherlands; for British Commonwealth, except Canada: Cleaver-Hume Press Ltd., 31 Wright's Lane, Kensington, London, W. 8, England, 1954.

This volume includes the nor-steroids, steroid hydrocarbons, and their halogen, nitrogen, and monohydroxyl derivatives as well as closely related degradation products. The structural formula, properties, methods of formation, and reactions of each substance are described. Such compounds as pregnenol, androstenol, 7-dehydrocholesterol, cholesterol, ergosterol, stigmasterol, and sitosterol, as well as their parent hydrocarbons and derivatives, are included. Literature has been consulted up to 1954 on the structure and configuration of the compounds.

Management of Disorders of the Autonomic Nervous System. By Louis T. Palumbo, M.D., Chief, Surgical Service, Veterans Administration Hospital, Des Moines, Iowa. Cloth. $5. Pp. 186, with 23 illustrations. The Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1955.

This small book attempts a simplified coverage of the autonomic nervous system. The first three chapters deal with anatomy, physiology, and pharmacology; the fourth describes tests and changes following surgery; and the last six chapters discuss diseases in various regions of the body. The illustrations are simplified schematic drawings showing areas of denervation. All topics are treated briefly giving conventional opinions supported by several references. The manual should aid the medical student entering into the clinical subjects. It should also aid the physician who is not familiar with the basic principles of disorders and diseases of the autonomic nervous system. It does not develop its topics sufficiently to afford a good source for knowledge concerning therapy or for reference material.

Transplantation of Tissues: Cartilage, Bone, Fascia, Tendon, and Muscle. Volume I. By Lyndon A. Peer, M.D., Clinical and Research Director, Rehabilitation Center for Plastic and Reconstructive Surgery, St. Barnabas Hospital, Newark, N. J. Cloth. $13.50. Pp. 421, with 163 illustrations. The Williams and Wilkins Co., Mt. Royal and Guilford Aves., Baltimore 2, 1955.

In the past quarter century there have been such rapid and changing strides regarding the transplantation of tissue that it has been imperative that someone gather this experimental and clinical material together. The author, a scientific investigator and surgeon, has done just that and has competently evaluated what has been put forth. This volume is written for the physician, surgeon, and medical student. It tells what happens to autogenous, homogenous, and heterogenous tissues when they are transplanted into human beings and other animals. An introductory part of the book reviews the human tissue cell, its behavior, and how it is affected by transplantation. Subsequent chapters treat each tissue separately as to its histological change, the basic experimental value, and clinical application in the treatment of specific conditions. The book becomes repetitious in parts, and the author has a tendency to insert many of his own pet clinical usages of various transplants. These are only minor discrepancies in an excellently arranged textbook that contains simple instructive illustrations, descriptive photomicrographs, a subject and author index, and an exhaustive bibliography.

Experimental Design and Its Statistical Basis. By D. J. Finney, M.A., Sc.D., F.R.S. The Scientist's Library: Biology and Medicine, edited by Peter P. H. De Bruyn, M.D. Cloth. $4.50. Pp. 169. University of Chicago Press, 5750 Ellis Ave., Chicago 37; Cambridge University Press, Bentley House, 200 Euston Rd., London, N.W.1, England; University of Toronto Press, Toronto 5, Canada, 1955.

This book offers chapters on randomized blocks and Latin squares, incomplete block designs, factorial experiments, sequential experiments, biological assays, and the selection of a design. The reader is assumed to be adept at handling point binomials, to understand the analysis of variance, to be reading the book consecutively rather than as a reference, and to have at hand a library of tables and the introductory textbooks listed in the bibliography. This last requirement results from the fact that the author sometimes devotes several pages to a subject like contravariance without supplying either a usable definition or an adequate example. The author deprecates (page 3) the tendency of biologists to "select textbooks of statistical methods almost entirely by the criterion of easiness to read." He makes this one harder by omitting conjunctions that might help the reader to discern the relation between ideas and by using elliptical phrases like "number of treatments" when he really means "number of kinds of treatments." The book can be recommended to advanced students of biometry.

Control of Communicable Diseases in Man. Official report of American Public Health Association. Eighth edition. Paper. Pp. 219. American Public Health Association, 1790 Broadway, New York 19; United States Department of Health, Education, and Welfare, Public Health Service, Washington, D. C., 1955.

This booklet has passed through sufficient editions to insure its usefulness and reliability. The contents are arranged in alphabetical order so that one may, even without referring to the table of contents, look for ascariasis, blastomycosis, diphtheria, or any other disease that is described. Each disease is taken up under identification, etiological agent, source and reservoir of infection, mode of transmission, incubation period, period of communicability, susceptibility and resistance, occurrence, and methods of control. This is a practical and handy little volume that should be found useful by nearly all practitioners, public health workers, and others who are interested in the control of communicable diseases in man.

Diseases of the Ear, Nose and Throat. By William Wallace Morrison, M.D., Professor of Otolaryngology and Director of Department, New York Polyclinic Postgraduate Medical School and Hospital, New York. Foreword by Arthur W. Proetz. Second edition. Cloth. $10. Pp. 756, with 359 illustrations. Appleton-Century-Crofts, Inc., 35 West 32nd St., New York 1, 1955.

Like its predecessor, the second edition of this book is directed at undergraduate medical students and general practitioners. It stresses the practical rather than the theoretical and deals primarily with common ear, nose, and throat conditions, touching briefly on rare diseases. The field is competently covered from the points of view of anatomy, physiology, pathology, diagnosis, differential diagnosis, and therapeutics. The illustrations are drawn by the author, who has had many years of experience with chalk drawings to illustrate lectures for students.

Medical and Public Health Laboratory Methods. Edited by James Stevens Simmons, S.B., M.D., Ph.D. and Cleon J. Gentzkow, M.D., Ph.D., Bureau of Laboratories, Department of Health, Commonwealth of Pennsylvania. Successor to fifth edition of Laboratory Methods of the United States Army. [Sixth edition.] Cloth. $18.50. Pp. 1191, with 124 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1955.

This book is a successor to the fifth edition of Laboratory Methods of the United States Army. There are many contributors, the coverage is extensive, and for the purposes intended it is complete. It is easy to read and adequately illustrated and has sufficient data that can be applied to practical problems. The book is assured of continued acceptance by those familiar with its predecessors. It is a handy reference book that is sufficiently comprehensive for practitioner and student, and it lends itself well to everyday desk use and to integration with other volumes containing more detailed descriptions that are more specialized in approach.

QUERIES AND MINOR NOTES

PROLONGED ANTICOAGULANT THERAPY

To the Editor:—*A 37-year-old man recently suffered an acute posterior myocardial infarction. He is not obese, has no hypertension, and has no diabetes mellitus. He had been in excellent health until struck suddenly by his infarction. What is your opinion as to the advisability of keeping him indefinitely on anticoagulant therapy?* *M.D., Arizona.*

Answer.—The question of whether the patient above described should be kept indefinitely on anticoagulant therapy cannot at present be conclusively answered. Patients may have one myocardial infarction and live for 20 years or more without a second one. It would seem in such cases that prolonged anticoagulant therapy would represent a large and unjustified investment in time, money, and care. However, this is not the usual story, and most patients who have one myocardial infarction suffer a series of subsequent thromboembolic episodes, some of which may be myocardial infarctions and others involve the peripheral arteries of the brain, the extremities, the kidneys, and other parts of the body. Evidence is accumulating that suggests that patients remaining on long-term anticoagulant therapy after their first or after subsequent myocardial infarctions have a definitely better prognosis in terms of future thromboembolic complications than patients who are not kept on this therapy. The present patient seems to be suitable for this approach, especially in that he does not have hypertension. The family history in this patient might be important. If numerous members of his family have suffered thromboembolic conditions, this would favor the use of long-term therapy, especially in view of his youth. The geographical and economic factors are also of importance. If good anticoagulant therapy is easily available to the patient and if he can afford it, such care is probably justified in the light of the present knowledge. Certainly if he should suffer a second thromboembolic episode this would be indicated, if at all possible. The risk of waiting for the second episode to occur is, of course, a considerable one since it might be fatal or produce permanent disability.

VITAMINS AND IRON FOR ATHLETES

To the Editor:—*I am the athletic physician of a university and have been interested in the nutrition of athletes. It has been customary here to give daily to each football player a combination of vitamins and iron such as perihemin. In my opinion, this is an unnecessary expenditure of money and of little value as these athletes get an abundance of food and a well-balanced menu.* *M.D., Florida.*

Answer.—The Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association, in March, 1955, expressed its opinion on the mass administration of vitamins to athletes and other related practices. Its resolution states, "In 1953 the Joint Committee on Health Problems in Education, with reference to the influence of oxygen administration to athletes, concluded that 'valid scientific evidence in support of the value of oxygen in athletic competition is lacking.' The committee was of the opinion then, and continues to feel, that the anticipation of help from oxygen might encourage the athlete 'to exert himself beyond the limits he has learned to expect from instinct and experience,' and, therefore, recommended 'that the use of oxygen for such purposes be disapproved.' Instances similar in nature have been reported involving the administration of drugs to stimulate athletes to greater activity or to narcotize an injured part for purposes of continuing play. These practices, along with mass medicine such as the administration of vitamins and other products, in the opinion of the committee, constitute poor medicine and worse education. They likewise represent an unfortunate ethical practice. The committee, therefore, believes that such practices should be disapproved."

VACCINATION AGAINST POLIOMYELITIS

To the Editor:—*In a query in* The Journal, *June 18, 1955, page 619, about postponing mass vaccination against poliomyelitis until next winter, the consultant said: "There are many reasons why vaccination might better be done in the winter rather than in the poliomyelitis season." Please discuss this question.* *M.D., New York.*

Answer.—The reasons why vaccination might better be done in the winter rather than in the poliomyelitis season are basically those that would seek to avoid any complication arising from injections made in an area while poliomyelitis is prevalent. Among them are given a few. 1. A variety of injections, especially those made by the intramuscular route, appear to induce paralytic poliomyelitis in persons who otherwise escape without distinct paralysis. This apparently is most likely to occur in children during presumed viremic stage of infection with a result that there is a localization of paralysis in the area of injection. 2. Since the purpose is to achieve as high a degree of resistance as possible from vaccination in advance of exposure to poliomyelitis, it is evident that in order to obtain the preventive effect, vaccination should be done before the period of exposure. Hence, the period of vaccination can be prolonged if begun in the winter, and a higher degree of resistance can be effected by summer. 3. Enhanced resistance established in the winter could be further boosted by natural exposure in the summer.

ANGIONEUROTIC EDEMA

To the Editor:—*May I have the latest treatment for angioneurotic edema?* *F. S. Marnell, M.D., San Diego, Calif.*

Answer.—There is nothing new in the treatment of angioneurotic edema. Simple palliative treatment consists of the use of antihistamines. In some cases ephedrine may be additionally helpful. In acute cases, or in edema of the larynx, epinephrine intramuscularly may be advisable. Cortisone, hydrocortisone, meticorten, or corticotropin (ACTH) may be advisable in obstinate cases. However, these drugs require several hours to a couple of days to produce effect. In some instances the use of nonspecific therapy may be helpful. Of course, the possibility of an allergy to a drug or food should be investigated.

PSORIASIS

To the Editor:—*What does chemical analysis of the scales of psoriasis reveal? Is there any evidence suggesting that psoriasis may be a metabolic disorder or that it may be related to a lipodystrophy?* *M.D., Pennsylvania.*

Answer.—In Rothman's new book, "Physiology and Biochemistry of the Skin," University of Chicago Press, 1954, it is said that normal stratum corneum cells contain high levels of cystine: psoriatic scales contain less cystine but more cysteine and methionine (S-H groups). In psoriasis the normal ratio in the skin of the amino acids histidine, lysine, and arginine, 1:6:7, is converted to 1:6:15 with the relative amount of arginine more than doubled. Ash content is increased in psoriasis as in all inflamed skin; the water content and chloride values are increased, and the potassium values are almost doubled. More carbon dioxide is delivered through psoriatic skin than through normal skin. As evidence of a metabolic factor in psoriasis are the following conditions: a deficiency perhaps in the phosphorylation of glucose content of the uninvolved skin of psori-

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

atics, reports of increased levels of plasma lipids in some patients with psoriasis, a reduction of alpha, lipoproteins, and an increase in beta lipoproteins in several patients with psoriasis as determined by paper electrophoresis of plasma.

SEVERAL DRUGS GIVEN SIMULTANEOUSLY

To the Editor:—*It is common hospital practice to administer several drugs of different actions simultaneously. Does interaction among these different drugs occur in the stomach contents so as to alter the physiological and pharmacological properties of these drugs?*

Aaron M. Lefkovits, M.D., Memphis, Tenn.

Answer.—This is a difficult question to answer since no definite chemical or biological types of drugs, or even groups of agents are given. Therefore, on purely theoretical grounds, one would expect the following agents with different actions to be altered to such an extent that their "usual" pharmacological level of activity could not be anticipated, viz: hydrochloric acid and the antacids; penicillin and oxidizing agents; tannic acid and salts of heavy metals; alkaloids and salts of heavy metals, as well as halides, carbonates, hydroxides, salicylates, benzoates, and borates; glycosides are incompatible with alkalis, mineral acids, and enzymes; ferric and ferrous salts are incompatible with tannic or gallic acids; fixed oils form soaps with hydroxides; and resins are precipitated from alcoholic solutions. It is recommended that the following substances be prescribed alone: strong mineral acids and alkalis, alkaloids, arsenic, iodides, iron, mercury and silver salts, methenamine, salicylates, and tannic acid.

Goodman, L. S., and Gilman, A.: Pharmacological Basis of Therapeutics: A Textbook of Pharmacology, Toxicology, and Therapeutics for Physicians and Medical Students, ed. 2, New York, the Macmillan Company, 1955, pp. 1774-1775.

HYPERTENSION

To the Editor:—*I have been using rather conservative doses of antihypertensive drugs in the treatment of hypertension. I am under the impression that there has been an increased incidence of coronary insufficiency in my patients. Are there any controlled studies bearing on this subject?*

M.D., Pennsylvania.

Answer.—The published evidence and much that is unpublished suggests that it is unusual for myocardial ischemia or coronary insufficiency to be elicited or to be increased by the antihypertensive drugs. This statement is contingent on the condition that the drugs are used carefully. Large overdose, say of hexamethonium, could easily induce insufficiency, but this is an abuse, not a use, of the drug. An example of the published reports is that of A. E. Doyle and J. A. Kilpatrick (Methonium Compounds in the Angina of Hypertension, *Lancet* 1:905-908, 1954).

BULLOUS LESIONS

To the Editor:—*A 4-year-old girl developed large bullous lesions of both feet after wearing a new pair of patent leather shoes. Where can I have her shoes tested to determine the cause of this condition?*

Earl T. McGhee, M.D., Dalton, Ga.

Answer.—If the chronologic relationship between the wearing of the new pair of patent leather shoes and the first appearance of large bullous lesions of both feet is certain, it is highly probable that the eruption was due to an allergen or irritant in the shoes. As a rule dermatitis produced by an allergy to ingredients of shoes appears on the dorsa of the toes and foot, especially the dorsum of the great toe and on the pressure areas on the sole of the foot, rather than between the toes, as is most common in fungous infections. The only way to test the thesis is to apply patch tests to the patient with the various materials of the shoes by cutting out small pieces and applying them with proper patch-test technique. The problems and technique of testing are outlined in many places in the dermatologic literature, such as "Dermatology: Essentials of Diagnosis and Treatment," by Sulzberger and Wolf (Chicago, Year Book Publishers, Inc., 1952). An excellent article devoted to the particular subject of shoe dermatitis is that by Harry Shatin and Milton Reisch (Dermatitis of the Feet Due to Shoes, *A. M. A. Arch. Dermat. & Syph.* 69:651-666 [June] 1954).

HYDATIFORM MOLE

To the Editor:—*Please outline the follow-up care of hydatiform mole? The patient is doing well three days after a dilatation and curettage. I plan to check a quantitative Aschheim-Zondek test at monthly intervals. Is a Papanicolaou stain or vaginal smear of value in these cases? Would testosterone increase chances of prevention of growths of any remaining mole fragments?*

M.D., Arkansas.

Answer.—The danger of malignancy following a hydatiform mole is low. The pathological grading of the mole and curettings will be helpful in prognosis. The qualitative tests for chorionic gonadotrophin will usually be negative by one month post partum; if positive, a quantitative test may be done. Persistent or irregular bleeding with subinvolution of the uterus are positive clinical signs. If all are negative and normal menstrual bleeding ensues, one or two further qualitative chorionic gonadotrophin tests should be sufficient. Because a new pregnancy will confuse the follow-up, a period of six months should elapse before pregnancy is advised. Occasionally, in the presence of chorioma, the Aschheim-Zondek test may be negative and then turn positive. Should there be clinical signs of subinvolution and bleeding with a high quantitative Aschheim-Zondek test and rising titer, another dilatation and curettage may be helpful, bearing in mind that invasive moles may not be accessible to the curette. The main feature of any follow-up or therapy is conservatism. This consultant knows of no study reporting the relationship between cytological smears and prognosis after molar abortions. Similarly, cases have been reported where testosterone has been used in the treatment (empirical) of choriocarcinoma with metastases, but there is no indication for its use in this case.

SULFATHIAZOLE

To the Editor:—*Is sulfathiazole a dangerous drug? Should its use in the forms of suppositories (for vaginal infections) or chewing gum be continued?*

Robert N. Monfort, M.D., East Lansing, Mich.

Answer.—The use of sulfathiazole has been virtually abandoned in favor of equally effective and less toxic sulfonamides. Experience gained in World War II has shown that the use of crystalline sulfonamides and of sulfonamide ointments, lotions, and creams as topical agents was not successful in the management of wound infection or in treatment of infections of the skin or mucous membranes. Vaginal suppositories and chewing gum containing sulfathiazole are probably of little or no value and carry some risk of producing sensitivity reactions.

COLORED SOCKS

To the Editor:—*I have heard patients advised not to wear colored socks on feet injured with lacerations because the dye may be absorbed through the wound. Please comment on this.*

M.D., Washington, D. C.

Answer.—Finished dyes intended for textile use are comparatively harmless for garment wearers, although in the intermediate stages of dye manufacture distinctly harmful exposures could appear. The reservation in the foregoing statement relates to possible sensitization leading to allergic responses. Almost any chemical may prove to be a sensitizer for a few persons. Most sock dyes will fade on washing, and bleeding under the action of perspiration sometimes discolors skin. Many physicians in treating fungal infections and other open skin lesions of the feet often recommend that patients wear only white socks. Precise justification for this may not be well founded. In a few instances, dermatitis has been attributed to socks, but this does not warrant a quick conclusion that either the dye or the basic yarn, such as nylon, is the source. Yarns may be treated with a variety of finishing substances, some one or more of which may prove to be the offender. With lacerations of the feet, wearing of colored socks involves no common peril. Pyogenic infection is more of a prospect, and in the presence of any substantial laceration or abrasion, the assumption is that a suitable bandage or other protection would be applied.

ATRESIA OF AUDITORY MEATUS

TO THE EDITOR:—*A male child was born on June 26 with an imperforate external acoustic meatus on the right. The right ear is only about half the size of the left, and the tragus seems to occupy the position of the meatus. The child seems relatively normal otherwise. When should treatment be instituted, and what treatment is likely to give the best results?*

Leslie A. Lambert, M.D., East Tawas, Mich.

ANSWER.—Congenital atresia of the external auditory meatus is usually associated with a normal inner ear and cochlear nerve; therefore, the plastic construction of an external auditory meatus with a substitute tympanic membrane generally results in a useful improvement as well as improved cosmetic appearance. Due to the anomalous structures this operative procedure offers certain technical difficulties so that it should be undertaken only by an otologist experienced in endaural surgery. Since the child referred to has a normal ear on the opposite side, he will develop speech at the normal age, and there is no urgency in correcting the atresia. The operative procedure is more readily done when the child is around the age of 12 than in younger children. Following the creation of a patent meatus, further plastic surgery can be considered if indicated, to improve the cosmetic appearance of the auricle.

PIGMENTATION IN PULMONARY DISEASE

TO THE EDITOR:—*Please discuss pigment of the face and trunk in chronic pulmonary disease. I refer to a diffuse tanning effect that may be seen in far-advanced lung disease and not merely cyanosis.*

Edward Shanbrom, M.D., West Haven, Conn.

ANSWER.—Pigmentation of the body as a result of, or coincident with, disease of the chest is uncommon. Perhaps the most common cause is an involvement of the adrenals by amyloidosis or atrophy along with a coincidental heart or lung involvement. Such involvement may be one of several types. It may be first, a caseous tuberculosis of the adrenals along with a chronic pulmonary tuberculosis. This combination is rare. Brown (cited in Rountree, L. G., and Snell, A. M.: A Clinical Study of Addison's Disease, Philadelphia, W. B. Saunders Company, 1931) observed only two cases of Addison's disease in 2,570 patients, while Bronfin and Guttman (*Am. Rev. Tuberc.* 31:1, 1935) found only two cases in 4,500 patients. More common, but still rare, is amyloidosis of the adrenals. In 100 autopsies of chronic pulmonary tuberculosis, Bronfin reported 18 with amyloid disease, 14 of which had amyloidosis of the adrenals, mainly in the cortex. There were five that had pronounced symptoms of Addison's disease (adrenal cortical hypofunction) with some freckling and/or pigmentation of the forehead, nose, and sometimes the face, neck, and trunk. There was not the usual type of pigmentation seen in Addison's disease like the pigmented mucosa, periorificial, and extensor surfaces. Only sallowness or tanning of the face and chest and freckling, which was usually ascribed to heliotherapy by the patients. Five other cases had some symptoms, but only one had any pigmentation of the skin. The relationship of pigmentation to destruction of the adrenals is not constant. Sometimes there may be what appears to be complete destruction of the cortex with few or no signs of pigmentation. It is possible, as Bronfin stated, that it may depend on the destruction of the medulla rather than the cortex. Chromaffin tissue elsewhere may play a role. Still more uncommon is adrenal disease with pigmentation that may be due to primary atrophy of the adrenals caused by tumors (Hodgkin's, hypernephroma, and other masses) that may press on the organ and cause its destruction. Hypothetically, longstanding passive congestion may cause pigmentation of the skin as in mitral stenosis and especially inflow stasis caused by partial obstruction of the superior vena cava as in Hodgkin's disease or benign tumors.

MYOCARDIAL INFARCTION AND WORKMEN'S COMPENSATION

TO THE EDITOR:—*What is the consensus regarding the relationship of effort and myocardial infarction, with reference to the Workmen's Compensation Act?* *M.D., New York.*

ANSWER.—The tendency has been to use the term "myocardial infarction" unqualified in any way. One thus does not concern himself with the distinction between infarction due to coronary occlusion and infarction in the presence of a patent coronary artery. Dr. Arthur M. Master and his associates insist that this distinction must be made because, when there is no acute occlusion, the necrosis or infarction is subendocardial, and, as in angina pectoris, it is precipitated by effort and, therefore, is compensable. On the other hand, his group has amassed a good deal of evidence to show that coronary occlusion is not affected by events in the external environment, and occurs as an end-result of longstanding atherosclerosis, irrespective of what the patient is doing or what is his state of inactivity. In general, internists and cardiologists believe that effort does not precipitate myocardial infarction due to coronary occlusion. However, many believe that this may occur on very rare occasions. They cite a case or two, for example, in which a man had occasion to perform severe physical exertion and developed chest pain or pressure, with all the clinical and electrocardiographic evidence of a coronary occlusion. However, most pathologists feel that a coronary occlusion takes hours to weeks to form and that the effort in this particular instance merely made the pain more severe or apparent. In other words, the effort and coronary occlusion were coincidental and were not causally related. Hence, we have a group, as exemplified by Dr. Master and his associates, who believe that the classical coronary occlusion is never precipitated by effort, a group who feel it is precipitated in the rarest of instances and, finally, a group who feel that effort frequently causes coronary occlusion. Dr. Ernst Boas was the chief exponent of the last group. Medical witnesses who belong to groups 2 or 3 would influence a referee board to rule that the coronary occlusion is compensable. Since the tendency is to give the workingman every "break," his case would probably be judged compensable no matter what is the physician's opinion as to the relationship of physical exertion and myocardial infarction.

FEEDING PROBLEM CHILD

TO THE EDITOR:—*Kindly outline the solution of a feeding problem in a 4½-year-old otherwise normal child. She refuses to eat unless fed. The parents are concerned about malnutrition if they follow my advice of only allowing the child to feed herself.*

M.D., Pennsylvania.

ANSWER.—Insistence on being fed is an infantile manifestation. You are absolutely right in your advice of only allowing the child to feed herself. Hardly ever will such a child go over three days, and there is no danger of malnutrition. However your problem is more to treat the parents than the child. Change her environment at meal time as completely as possible, as in new surroundings a new habit can be started sooner. Change the place of eating, change the dishes, and change the person who serves her. It should be made clear to her that she is making a new start in life. Solid foods that require chewing and which, at the same time, she is known to enjoy should be offered. Raw vegetables and fruits are well suited for this purpose. Give her a dull-edged knife to practice cutting soft foods. Well-cooked meat or potato may be tried, and let her spread her bread with butter or jam. She is also old enough and will be greatly benefited if she can eat with children her own age as at a kindergarten or nursery school. If cooperation at home is not satisfactory a short stay in a hospital, obviously without the parents, will accomplish the desired results.

ESTROGENS AND CORONARY DISEASE

To the Editor:—*I have read that decreased estrogenic production in postmenopausal women is statistically correlated with clinical coronary artery disease. Is there any correlation between the frequency and severity of coronary artery disease in young women after the induction of an artificial menopause? Some sources state that hormone studies have demonstrated a comparable metabolic disturbance to that in women undergoing normal menopause. The problem of hysterectomy and its disturbances of the endocrine and cardiovascular system is of particular interest to me.* *M.D., California.*

Answer.—Experiments in chicks have suggested a favorable effect of ovarian hormones on experimentally produced coronary arteriosclerosis, and according to Wuest, Dry, and Edwards (*Circulation* 7:801, 1953) the hearts of bilaterally oophorectomized women showed at autopsy arteriosclerosis of a greater degree of severity than did controls. There is no reason to expect that hysterectomy would have any influence on coronary sclerosis.

TRICHINOSIS

To the Editor:—*Someone, supposedly an authority, has said that lamb or mutton may be infested with Trichinella. I am not aware that any animal but swine harbors this parasite. Is this so?* *J. J. Blue, M.D., Cedarville, Mich.*

Answer.—Trichinosis is found in such carnivorous animals as the hog, rat, dog, cat, fox, bear, marten, and mongoose, but there is no authentic record of the disease appearing in herbivorous animals. Infection in sheep would be most unlikely, although sporadic cases could not be definitely ruled out.

SEROLOGIC TESTS

To the Editor:—*In reading the query regarding serologic tests* (J. A. M. A. **158**:*1235 [July 30] 1955), I would like to mention an instance in my practice in which a multiparous patient (no change of spouse) whom I had previously delivered has come up with a similar situation. In order that the matter be finally settled, a Treponema immobilization test was performed (TPI) that indicated that syphilis did not exist since there was no reaction. This patient had always had negative serologic tests before, and the present pregnancy was the one in which a positive Kahn test was reported with eight Kahn units. From the result in this particular case, it would seem the TPI test is a final port of call to rule it in or rule it out.*

WETTING AGENTS IN ANTIBIOTIC MISTS

To the Editor:—*The Queries and Minor Notes section, April 30, page 1665, of* The Journal, *contains a discussion on aerosols. While I agree with the opinion about antibiotics, I would like to comment on detergent aerosols on the basis of long experience with these agents. Alevaire, containing one of the Tritons, was stated to be very irritating due to a pH of 10.0. Actually the pH of Alevaire is about 8.2 and is obtained not from Triton but from 2% bicarbonate of soda. Otolaryngologists have been using 2% to 5% solutions of sodium bicarbonate to liquefy mucus by instillation through tracheotomy tubes and bronchoscopes for decades, and it is a safe, nonirritating, accepted therapy in medical practice. I have used Alevaire on many patients, from 2 lb. (907.2 gm.) premature infants to elderly patients with bronchiectasis, over a five year period, and have never noted irritation. Judging from the more than 100 clinical papers mentioning the use of Alevaire it undoubtedly has been used hundreds of thousands of times. As far as I know, irritation is not reported in any of the articles. The only effect I have noticed, which can hardly be called irritation, is the sensation noticed by the patient on breathing the aerosol for the first time. The unaccustomed impingement of droplets and air stream of any aerosol, even water, on the palate and pharynx may cause a transitory uncomfortable sensation. This disappears after about five inhalations. I have tried in every way without success, to produce some toxic effect with aerosols of superinone (Triton WR1339), the detergent in Alevaire. Not the slightest respiratory difficulty occurred with the highest concentration in newborn hamsters who were born in the concentrated mist and lived exclusively in it 24 hours a day for six months. Under my care are several children who always sleep in an Alevaire mist. One boy with mucoviscidosis has been sleeping in it 8 out of every 24 hours for four years, with no toxic effects and excellent prophylactic results, On the other hand, many enzymes and detergents, including Duponal C mentioned in* The Journal *discussion, are so irritating that they cause a chemical bronchopneumonia, hyperemia, and edema of the lungs. Animals have died in three hours by having them breathe Duponal C in concentrated aerosol solutions. If reduced in concentration to a point where they are relatively nontoxic, they not only produce little beneficial effect, but may still cause some bronchial irritation.*

Contrary to the opinion expressed in The Journal, *drowning during aerosol therapy is impossible. The human lungs have a tremendous surface area, as large as a double-sized tennis court, and can absorb large quantities of fluid. Winternitz and Smith* (Proc. Soc. Exper. Biol. & Med. **16**:*55-56, 1919) have shown that dogs can tolerate tremendous amounts of fluid insufflated into the lungs. According to these investigators 20 cc. of water per kilogram of body weight can be instilled into the lungs without any harm. Potter (Report of the Fifth M&R Pediatric Research Conference, Columbus, Ohio, M&R Laboratories, page 53) rapidly instilled 150 cc. of water into a rabbit's lungs without respiratory embarrassment. She immediately removed the lungs. They weighed only 35 gm., indicating absorption of the fluid almost as fast as it had been injected. The vast majority of papers already published on Alevaire attest to its clinical effectiveness. It is excellent and unique for decreasing the surface tension of secretions and plugs, thus allowing them to be more easily expectorated or withdrawn by aspiration. This effect can be dramatically demonstrated by administering Alevaire (10 cc.) to a group of bronchiectatic patients one hour a day for two weeks and observing their sputum daily. The sputum invariably changes from a thick yellow or green material, difficult to expectorate, and accompanied by dyspnea and hacking cough, to a thin, watery material that is easily expelled. Expectoration will totally disappear in most cases and in others be reduced to a minimum amount that is not accompanied by respiratory difficulty. Detergent aerosol therapy is a relatively new and unique therapeutic concept that requires special techniques and equipment for administration. However, it has been my experience that most physicians, both general practitioners and specialists, are rapidly becoming familiar with the techniques and are finding them valuable in their practice.*

HYPOPHYSECTOMY

To the Editor:—*In* The Journal, *June 18, 1955, page 620, is a query on hypophysectomy for metastatic malignancy. In answering, the consultant states that in most cases of hypophysectomy the "only substitute therapy required is the simple administration of thyroid substance." A totally hypophysectomized patient cannot be managed in this way. These patients require adrenocortical hormone replacement in order to maintain life. The most reliable criterion that total hypophysectomy has, in fact, been accomplished is the rapid development of adrenocortical insufficiency when these hormones are withdrawn. Patients who survive this operation without the development of adrenocortical insufficiency have been proved to be incompletely hypophysectomized. The administration of thyroid hormone, on the other hand, is not essential for the maintenance of these patients, although it contributes greatly to their comfort by preventing the development of myxedema.*

LIVER DECOMPRESSION BY COMMON BILE DUCT DRAINAGE IN SUBACUTE AND CHRONIC JAUNDICE

REPORT OF SIXTY CASES WITH HEPATITIS OR CONCOMITANT BILIARY DUCT INFECTION AS CAUSE

Alfred A. Strauss, M.D., Siegfried F. Strauss, M.D., Arthur H. Schwartz, M.D.
William J. Tannenbaum, M.D., David D. Kram, M.D.
and
Walter W. Masur, M.D., Chicago

The possibility of using surgical decompression of the ductal system of the liver for relief of chronic jaundice resulting from subacute and acute hepatitis, usually due to a virus infection, first suggested itself to us many years ago when we were doing surgery in cases of congenital atresia of the bile ducts.[1] We found that atresia, or absence, of the excretory bile ducts in these newborn infants produced not only jaundice but also a marked increase of the connective tissue in the liver, causing cirrhosis. This we ascribed to the irritation secondary to biliary stasis. Even in extremely pronounced cases of jaundice where exploration revealed a large liver, deeply pigmented, with an increased amount of connective tissue, we were able to establish good biliary drainage within a few days if the intrahepatic ductal system was patent. A biliary fistula was formed by placing a catheter into the hilus of the liver proximal to the atresia. After jaundice had disappeared, secondary operations could then be done at a later date. For one or two days the fistula would yield a thin water-clear fluid that probably represented the mucous secretion of the ducts. Due to the increased intraductal pressure, the liver cells cannot function until the pressure is relieved by intraductal drainage. After 24 to 48 hours of decompression, the bile assumes its normal color and the jaundice subsides. Within a few months a definitive operation of the Roux Y type can be performed.

TYPES OF CASES BENEFITED BY SURGERY

We feel that insufficient consideration has been given to the surgical approach in the treatment of jaundice resulting from acute and subacute hepatitis on an infectious basis—by that we mean drainage of the common bile duct and decompression of the liver. The pathological process in many instances is not only confined to the liver but there is also inflammation and infiltration of the entire ductal system. This inflammation may vary in intensity; sometimes it may become so severe that a partial obliteration of the smaller ducts and also of the common bile duct is caused. It has been shown that the disease frequently originates not in the liver but in the bile ducts. We have seen, in patients with jaundice of long duration, infiltration of the distal portion of the common bile duct and of the papilla, causing dilatation of the ducts to three or four times their normal size. When these ducts are opened, bile mixed with pus escapes in large quantities. Depending on the chronicity of the process, more or less bile pigment will be present.

Clinically we have encountered three groups of patients with chronic jaundice or biliary stasis: first, those with severe colic-like attacks of pain; second, those without acute attacks and with mild jaundice; and third, those with a deep, silent jaundice. The jaundice in several patients of the second group was so minimal, the only presenting symptom being itching of the skin, that the condition therefore escaped diagnosis for some time. In all these three groups, the pathological condition consists of an inflammatory process in the distal portion of the common bile duct and in the papilla of Vater, producing infiltration, thickening, and finally narrowing of these structures. The intensity of this process may vary; at times it may involve the entire ductal system up to the finest biliary radicals.

In cases of acute and subacute hepatitis, usually due to a virus infection, the liver is usually larger than normal and edematous. Its color ranges from yellow to dark green in the more severe cases. In hepatitis of longer duration but of milder degree, the liver shows a marked increase in the interlobular connective tissue, which produces a picture ranging from a mild cirrhosis to that of

a hobnailed liver. Histologically, in addition to the increase in connective tissue, there is marked vacuolation and destruction of liver parenchyma, which in some cases resembles a liver with subacute yellow atrophy. The pancreas varies greatly in its consistency. It can be fairly firm and lobulated, or hard and diffusely swollen. There is usually a marked degree of peripancreatitis causing firm adhesions between the omentum of the lesser curvature of the stomach and the pancreatic capsule. The lesser omental cavity is often completely obliterated.

One of our patients had a severe infiltrating duodenal ulcer near the papilla of Vater that produced intermittent jaundice for a period of 10 years. The clinical picture eventually indicated severe liver damage, with the patient stuporous and in a semicomatose condition. After several duodenal hemorrhages, the patient finally underwent surgery. The operative findings were a liver about one-third its normal size, with a hobnailed cirrhosis, in addition to a large carbuncle-like infiltrating duodenal ulcer at the papilla of Vater. We performed a high subtotal gastrectomy. For the relief of the deep jaundice that was caused by the infiltration of the papilla of Vater and of the common bile duct, we anastomosed the gallbladder to the open end of the duodenum. The patient has remained well for 20 years. This case brings out two important points: 1. The liver cirrhosis was caused by an infiltrating duodenal ulcer of long standing that produced recurrent infections and obstruction of the common bile duct resulting in intermittent jaundice. 2. After decompression of the biliary system, the liver apparently completely recovered physiologically, since the patient is in perfect health 20 years after surgery.

Another patient with a history of jaundice of five months' duration, also critically ill at the time of surgery, underwent drainage of the common bile duct. Biopsy of the liver showed marked degeneration of the liver parenchyma and interlobular cirrhosis. Eight weeks later, at autopsy, the liver showed areas of marked regeneration with formation of new bile ducts. This shows that even in severe cases intraductal tension can be relieved by drainage of the common bile duct and that regeneration does occur in the liver when the intraductal and intrahepatic pressure is relieved.

We believe that, in some of the patients with jaundice due to acute or subacute hepatitis who do not improve under medical management, surgery should be considered. We refer to the patients in whom, in addition to the hepatitis, inflammation of the intrahepatic as well as of the extrahepatic bile ducts is present. It is our contention that the inflammatory process produces an obstruction of the bile flow at the papilla of Vater. This in turn causes an increase of the intraductal pressure that is transmitted toward the liver parenchyma leading to further breakdown of liver cells, necrosis, and increased jaundice. If this vicious cycle is interrupted by drainage of the common bile duct, excretion of bile will take place followed by improvement of liver function, leading eventually to complete alleviation of the jaundice. Frequently in such instances, not only the wall of the common bile duct is infiltrated and thickened but also the surrounding areolar tissue. The extreme hyperemia represented by many small blood vessels makes the identification and dissection of the common bile duct quite difficult. There is usually a large amount of bleeding from this hemorrhagic area during the dissection. In occasional cases, when the involved structures have been small, we have used special magnification eyeglasses. In many instances we were able to insert only the smallest catheter, usually employed on premature infants. A regular French catheter, with its tip cut off to insure better drainage, is sutured into the common bile duct, pointing toward the liver. Since such a catheter has to remain in place for a considerable length of time, sometimes for a period of six months, we use silk for suture material. Ordinarily, for one or two days, only a small amount of a colorless, watery liquid returns from the catheter, but, after this, a steady flow of bile begins, ranging at first from 60 to 90 cc., until, in the second postoperative week, 300 to 500 cc. of good normal bile is recovered in a 24 hour period. This is due to the relief of the intraductal pressure against the liver cells. Concomitantly, the clinical condition of the patient improves and the jaundice decreases. Liver function tests usually return to normal within several months. A typical case history of a patient with subacute hepatitis with severe jaundice illustrates this.

REPORT OF A CASE

A 26-year-old man was first admitted to the hospital with clinical and laboratory findings of fairly severe acute hepatitis with jaundice. Under a conservative regimen he improved sufficiently to be discharged at the end of five weeks; however, after three weeks at home, his jaundice increased again, and he was returned to the hospital approximately eight weeks from the known onset of his disease. His liver at that time could be palpated three fingerbreadths below the costal margin, and liver function tests showed a relapse of the hepatitis. On the day of readmission, the serum bilirubin reached a level of 40 mg. per 100 cc. The cholesterol ester fraction had decreased steadily, and four days after admission it was zero. Whereas urobilinogen had been present in considerable amounts in the urine and in the feces during the period of remission, it had now disappeared completely. The abdominal findings were much more pronounced during the second hospital stay; the liver was larger and more tender, and the spleen could now be easily palpated. The patient's clinical condition continued to deteriorate, with the patient mentally depressed and drowsy. Therefore, after the patient had been in a continuously jaundiced condition for almost three months, we decided, in consultation with the internist, to do an exploratory laparotomy with common bile duct drainage.

The operative findings were severe infiltration of the entire hepatoduodenal area involving the bile ducts as well as the periductal areolar tissue. The liver was markedly enlarged and firm. The gallbladder was small and empty. Exposure of the common bile duct met with great difficulty. There was a considerable amount of bleeding from the small blood vessels within the periductal tissue. The lumen of the common bile duct was very small and empty. Thus, it was necessary to use the smallest catheter available, which was the catheter used on premature infants. This was passed into the proximal portion of the duct and sutured with silk. Within 24 hours, the usual watery, lightly colored bile appeared, being 150 cc. in volume. Twenty-four hours later the bile was almost normal in color and character. On the fifth postoperative day there was 360 cc. of normal looking bile, and this increased steadily until, finally, up to 780 cc. was excreted in a 24 hour period. This again proves that, when the intraductal pressure against the liver cells is relieved they will start functioning. This relief is accomplished by drainage of the common bile duct. At the same time that the jaundice gradually decreased, liver function tests returned to normal, and the patient left the hospital in excellent condition three months after the operation. Now, two years later, the patient is well, and there has been no recurrence of the disease.

It seems to us that the impaired outflow of bile from the infiltrated ductal system causes intraductal pressure and enough back pressure in the liver against the liver cells to interfere with the normal function of the liver cells and that drainage of the common bile duct will relieve this tension, thus contributing to the establishment of a normal bile flow. Irrigation of the catheter is ordinarily unnecessary, except when a mucous plug or sediment obstructs the passage of bile once drainage has started.

EVALUATION OF CASES

From a series of 26 operative cases of this type, 4 patients were not relieved of their jaundice and died several months later; the remaining 22 made a complete recovery. They are well, and their liver function tests are normal. We will concede that some of these patients might have recovered without our resorting to surgical drainage of the common bile duct; however, we feel that the recovery rate in this series could not have been attained by medical therapy alone. All these patients had had an adequate trial period of medical treatment and were in poor condition at the time of surgical consultation; some of them were semistuporous, with liver function tests indicating extreme liver damage.

Another type of subacute or chronic hepatitis has its basis primarily in an infection of the common bile duct and the papilla of Vater. In time such a duct will become thickened and infiltrated. At laparotomy there is usually tremendous enlargement and dilatation of the common bile duct. Exploration of the duct reveals a large amount of serous to seropurulent exudate. On probing the duct one encounters difficulty in passing through the papilla of Vater, indicating an obstructive process at that site. Patients with this type of disease as a rule recover much more quickly from their jaundice and hepatitis than those who primarily have hepatitis. In some of these cases of long-standing (three to six months) the patients pass postoperatively into a phase of acute hepatitis that clinically resembles acute yellow atrophy of the liver. This happened in one case in our series of 34 patients where the autopsy findings were that of an acute necrosis of the liver with acute yellow atrophy. The other 33 patients recovered uneventfully. In 1933 [2] we reported a series of 58 cases of subacute or chronic jaundice due to cholangitis and infiltration of the papilla of Vater causing biliary stasis. At that time we recommended drainage of the common bile duct. If jaundice recurred after this procedure, we advised choledochoduodenostomy with gastroenterostomy. In recent years we have treated such cases of recurrent jaundice after common duct drainage with a Roux Y operation.

SURGICAL TECHNIQUE

Recurrent jaundice following common bile duct drainage means contraction and infiltration of the distal portion of the common bile duct and of the papilla of Vater due to connective tissue formation. The best operative procedure to relieve this type of jaundice is the one-arm Roux Y operation as described by Cole, Ireneus Jr., and Reynolds.[3] In some of our earlier cases, where we used rubber catheters of various sizes for an anastomosis between the liver or the hepatic ducts and the jejunum, we were able to establish permanent bile drainage. These patients are still living and well. In later years we began using the vitallium tube described by Pearse [4] for choledochojejunostomy and in surgical procedures for congenital atresia of the bile ducts. We found the vitallium tubes more satisfactory, but even some of these were expelled into the intestinal tract. As a consequence of this experience, we designed a vitallium tube with sharp prong-like projections at the upper end (fig. 1, 2, and 3), and we are using this tube at the present time. When the tube is placed into the hilus of the liver, the prongs pierce the surrounding tissues so that it is almost impossible to dislodge the tube from its position. This has been successfully employed in several patients.

The opening in the common bile duct or at the end of the common bile duct as it enters the liver is dilated. The vitallium tube is inserted into this opening, and silk purse-string sutures are used to fasten the tube (fig. 1). A loop of jejunum about 14 to 16 in. from the ligament of Treitz is divided. An end-to-side anastomosis with waxed silk sutures is made between the proximal end of the divided jejunum and lower portion of the jejunum, approximately 2 ft. away from the area of transection. An opening is made in the transverse mesocolon, and the arm of the jejunum to be anastomosed to the stump of the duct, or to the hilus of the liver, is placed through this opening so as to make it retrocolic. A small opening should be made about 1 to 2 in. from the end of the closed jejunum (fig. 2*B*) and a fine forceps inserted to control the position of the vitallium tube. Interrupted sutures can then be placed in the jejunum, which is to be attached to the hilus of the liver (fig. 3*B*). Care must be taken to close this area carefully so as not to create tissue tension. The opening made in the jejunum by the forceps can then be closed. This procedure affords a double protection against the tube being dislodged: first, by the prongs fastened in the liver substance, and second,

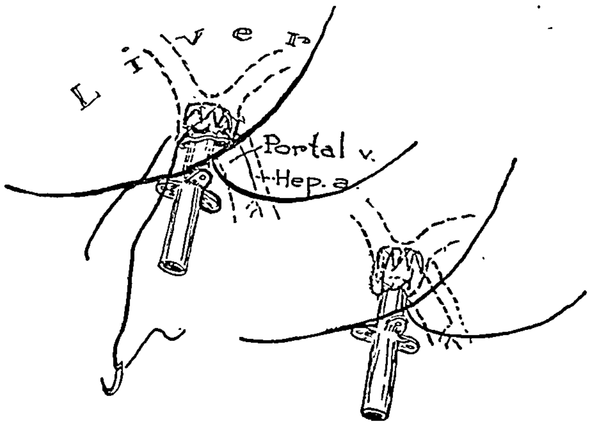

Fig. 1.—Vitallium tube lying within the hilus of the liver or within the common bile duct. The metal arms lie between the hilus of the liver and the closed purse-stringed jejunum.

[3] Cole, W. H.; Ireneus, C., Jr., and Reynolds, J. T.: The Use of Vitallium Tubes in Strictures and Absence of the Common Bile Duct, Ann. Surg. **122**: 490-521 (Oct.) 1945.

[4] Pearse, H. E.: Benign Stricture of the Bile Ducts Treated with a Vitallium Tube, Surgery **10**: 37-44 (July) 1941. Pearse, H. E.: Vitallium Tubes in Biliary Surgery, Ann. Surg. **115**: 1031-1042 (June) 1942.

by the metal arms of the tube lying between the liver and the closed purse-stringed jejunum. In some instances we included the arms of the vitallium tube in the closed jejunum, but we found that this was not as satisfactory. The opening in the mesocolon is sutured around the jejunum and its mesentery in order to prevent a herniation of loops of small intestine with possible obstruction (fig. 3*B*). The open end of the divided jejunum is purse-stringed with waxed silk (fig. 3*A*). This purse-stringed suture is tightened around the end of the vitallium tube, emerging from the hilus of the liver (fig. 3*A*). At that point, the metal arms of the tube are between the liver and jejunum; the jejunum is then attached to the hilus of the liver with interrupted silk sutures (fig. 3*B*).

We have used the procedure suggested by Cole of making valves in the arm of the jejunum to prevent a reflux of the intestinal contents into the hilus of the liver. Usually four such valves (fig. 4) are made. Interrupted sutures are used to fold the jejunal wall into its lumen, thus forming a valve. Two small rubber drains are placed along the hilus of the liver and brought out through a small stab-type incision, as a protection against possible bile leakage. These drains are ordinarily not removed until the 8th or 10th day.

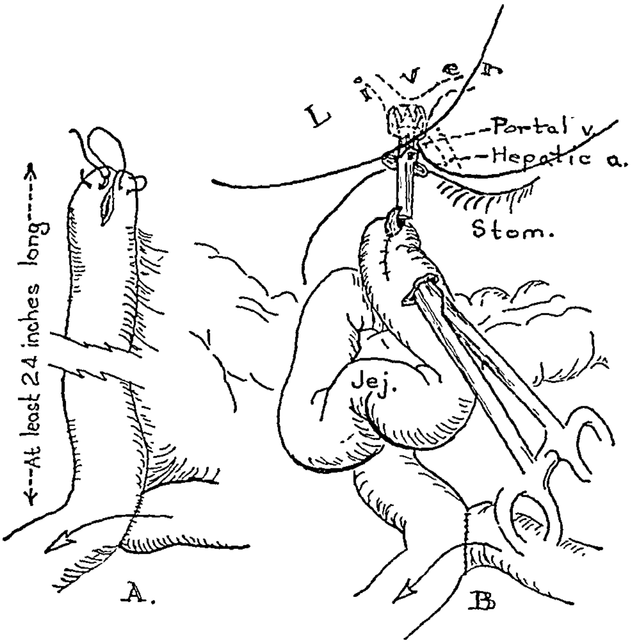

Fig. 2.—Closed blind end of the jejunum, *A*, with purse-string suture at least 24 in. from end-to-side anastomosis of jejunum and, *B*, vitallium tube in place. A forceps is introduced into jejunum to draw vitallium tube into lumen of intestine.

COMMENT

In many cases of chronic jaundice caused by an infectious process involving the duodenum, pancreas, and common bile duct, we feel that the infection might possibly start in the duodenum and then ascend into the common bile duct. The infectious process causes typical pathological changes in the lower portion of the common bile duct and in the papilla of Vater; namely, edema and infiltration that eventually lead to interference with the biliary outflow. The bile stasis created by this obstruction is transmitted into the liver and produces degeneration and vacuolation of the liver parenchyma, and, later, interlobular and periductal cirrhosis. Congenital obstruction in the common bile duct of the newborn infant illustrates such a sequence of changes. It is probable that in many patients whose cases were diagnosed as primary cirrhosis of the liver, not due to alcoholism or other chemical processes, the condition began as an infectious process in the biliary passages rather than in the liver itself. The reported history of the patient with a duodenal ulcer at the papilla of Vater that caused cholangitis, intermittent jaundice, and, finally, a hobnailed cirrhosis of the liver illustrates this point.

SUMMARY AND CONCLUSIONS

Surgical decompression of the liver and its ductal system by common bile duct drainage for a period of time until the patient is completely relieved seems to be fundamental in cases of jaundice of long standing that result from acute and subacute hepatitis, usually due to a virus infection, and in those cases in which the jaundice is due to primary ductal infection usually starting in the papilla and common bile duct and then extending up into the branches of the bile ducts into the liver cells, thereby producing a vicious circle of bile retention due to increased intraductal pressure. Common bile duct drainage relieves intraductal and intrahepatic pressure in (1) congenital atresia, (2) acute and subacute hepatitis, and (3) in cases resulting from infections of the papilla and bile ducts, probably due to an original duodenitis. In the first 24 hours only clear, watery bile is secreted from the ductal epithelium, showing that the liver cells cannot function under pressure. When this pressure is relieved, bile is secreted by the liver cells, as is shown by good bile drainage from the common bile duct catheter. Common bile duct drainage was done in a series of 26 cases of acute and subacute hepatitis with jaundice and in another series of 34 cases of cholangitic hepatitis with jaundice. The mortality rate in the first series was four and in the second series one.

If common bile duct drainage does not relieve the jaundice completely and permanently in the types of cases we have described or in those cases where the jaundice recurs after an interval of freedom, a one-arm Roux-Y operation is advocated. This has proved extremely successful.

TISSUE CULTURE ISOLATION OF COXSACKIE GROUP B VIRUSES IN ASEPTIC MENINGITIS

William M. M. Kirby, M.D.
and
Charles A. Evans, M.D., Ph.D., Seattle

It has become well established during recent years that Coxsackie group A viruses are the cause of herpangina and that group B strains are the etiological agents in epidemic pleurodynia (Bornholm disease).[1] The relationship of Coxsackie viruses to infections of the central nervous system is, however, much less certain. In many instances Coxsackie viruses have been isolated from the stools of patients shown to have poliomyelitis. Further, Coxsackie viruses are so widespread in nature that, despite isolation of these viruses from stool specimens and a rising titer of antibodies, it has been difficult to rule out the possibility that these agents were merely causing subclinical infections in patients with other diseases. On the other hand, persuasive evidence in favor of the etiological role of Coxsackie viruses in aseptic meningitis has been accumulated.[2] Particularly important is the fact that Coxsackie viruses have been isolated from the spinal fluid by at least three groups.[3] Coxsackie viruses have usually been isolated by injecting clinical specimens into suckling mice or hamsters. Until recently, these agents have not been recovered from clinical specimens by tissue culture. The present report describes a group of adults with a clinical diagnosis of poliomyelitis in whom a relatively large percentage of the infections were apparently caused by Coxsackie group B viruses. In all instances primary isolation and serologic identification of the virus was made in tissue culture.

PLAN OF STUDY

The study included 66 patients admitted to the adult infectious disease ward of King County Hospital from July through December, 1954, with a diagnosis of paralytic or nonparalytic poliomyelitis. The patients ranged in age from 13 to 38 years. All had fever, headache, stiff neck, and pleocytosis on admission. Stool specimens were collected as soon as possible after admission and were frozen until laboratory studies were performed. Serums were obtained for neutralization tests on admission and from three to six weeks later.

Methods of handling stool specimens and preparing tissue culture tubes have been described in detail elsewhere.[4] Briefly, fecal specimens were suspended in distilled water and freed of bacteria by centrifugation and the addition of antibiotics. The supernatant fluid was used for the inoculation of trypsinized monolayer cul-

tures of kidney epithelium obtained from rhesus monkeys. The cultures were observed daily for cytopathogenicity, and at least three serial passages were made before a specimen was considered negative. When cytopathogenic effects were observed, neutralization tests were carried out with the three types of poliomyelitis antiserums. Agents not neutralized by poliomyelitis antiserums were further tested against Coxsackie group B antiserums, types 1-4.[5]

In all patients, neutralization tests for poliomyelitis antibodies were performed on acute and convalescent serums, using the colorimetric assay method of Salk, Youngner, and Ward.[6] In addition, in patients from whom Coxsackie group B virus, type 2, was obtained, neutralization tests were performed against a B-2 strain, using virus obtained from one of the patients. These tests were performed with monolayer tissue cultures, using serial dilutions of patients' serums. In the patient whose stool specimens yielded Coxsackie B-4 virus, neutralization tests of acute and convalescent serums were also performed with B-4 virus.

TABLE 1.—*Virus Isolations from Fecal Specimens of Sixty-Six Patients with Clinical Diagnosis of Poliomyelitis*

Type of Patient	No.	Virus Not Isolated	Virus Isolated	Poliomyelitis			Not Typable
				Type 1	Type 2	Type 3	
All cases.......	66	15	51 (77%)	9	5	23	14
Paralytic	36	5	31 (86%)	8	4	18	1*
Nonparalytic	30	10	20 (67%)	1	1	5	13

* Poliomyelitis type 2 virus also recovered from later specimens.

RESULTS

Of the 66 patients, virus was obtained from the stools of 51 (table 1). Since in most years type 1 strains have been predominant, it was of interest that 23 (62%) of the 37 poliomyelitis strains isolated were members of type 3. It was further observed that the stools of 14 patients yielded cytopathogenic agents that were not neutralized by any of the three types of poliomyelitis antiserums. These agents were tentatively classified as "orphan" viruses. They caused rather slow, patchy degeneration of the monkey kidney cells over a period of 7 to 10 days. In contrast, the poliomyelitis viruses caused complete cytolysis within 48 to 72 hours. These differences in growth characteristics were so striking that as the study progressed it became possible during primary isolation to recognize the agents that were not poliomyelitis viruses. The possibility that more than one poliomyelitis virus was present in these specimens was excluded by the failure of a mixture of all three types of antiserums to prevent the slow, patchy degeneration. Indeed, in one paralytic case two types of poliomyelitis virus were present in a stool specimen; this was immediately suspected when rapid cytolysis occurred in the presence of each of the three poliomyelitis antiserums. Repetition of the neutralization test using appropriate combinations of antiserums established the fact that this specimen contained both type 2 and type 3 poliomyelitis viruses.

Using tissue culture techniques, essentially identical with those employed for poliomyelitis viruses, the 14 unknown strains were further identified as Coxsackie group B viruses. Of the 13 patients whose stools contained Coxsackie B-2 viruses, one was of special interest in that the first two specimens contained this virus, whereas the next three yielded poliomyelitis virus, type 2. Stools from the other patient yielded a Coxsackie B-4 strain. For these 14 patients, results of neutralization tests on acute and convalescent serums are presented in table 2. In the 13 patients whose stools yielded Coxsackie B-2 virus, a significant antibody titer against the homologous virus was present in all instances, and in most cases there was a definite rise in titer. The patient in case 14, from whom B-4 virus was isolated, showed a rise in antibody titer to this virus, but her serums contained no antibodies against the B-2 strain. Neutralization tests for poliomyelitis antibodies are also presented in table 2. In cases 1 through 5, antibodies were absent or present in low titer, indicating that these patients did not have a recent attack of poliomyelitis. This was in striking contrast to the results obtained in the 36 patients with paralytic poliomyelitis, all of whom showed a significant antibody titer with one type or another. In the other nine patients in cases 6 through 14 antibodies were present for poliomyelitis viruses. In some instances a rise in titer occurred, while in others a high titer was present in both acute and convalescent specimens. The possibility that some of these patients had recent infections with poliomyelitis virus cannot be excluded; the data are probably best regarded as inconclusive on this point. The patient in case 13, whose first two stools yielded Coxsackie B-2 virus and whose later specimens contained poliomyelitis type 2 virus, had a high antibody titer against both of these agents.

Twelve of the 14 patients were between the ages of 20 and 30, one was 34, and one 37. Ten were females, four of whom were pregnant (cases 1, 4, 5, 6; table 2); in three of these four patients antibodies against poliomyelitis viruses were absent or present only in low titer. One patient was admitted during July, three during August, six during September, and four in October. All 14 patients had fever, malaise, headache, and stiffness of the neck and back. The cerebrospinal fluid leukocyte count was above normal in all cases, but in 8 of the 14 it was under 100 cells per cubic millimeter. The clinical course in these 14 patients was similar to that observed in nonparalytic patients from whom poliomyelitis viruses were recovered. The temperature was normal within 4 or 5 days in most instances, and the patients were essentially asymptomatic within 7 to 10 days. All were completely well and had returned to their usual duties at the end of two months except for the patient in case 13, whose stools also yielded poliomyelitis virus, type 2. Slight weakness of one leg persisted for three months, but at the end of this time the patient had recovered completely and returned to work.

COMMENT

The most striking feature of the present study was the recovery of viruses other than poliomyelitis from 27.4% of patients whose stool specimens yielded cytopathogenic agents. Primary isolation was made with tissue culture (monkey kidney), and neutralization tests revealed that these agents were Coxsackie group B viruses. Prior to the advent of trypsinized monolayer tissue cultures Coxsackie viruses were rarely isolated by the tissue culture technique, and agents not neutralized by poliomyelitis antiserums have been commonly referred to as "orphan" viruses. It is apparent from the present study that, with techniques currently available, appropriate tests to exclude Coxsackie viruses must be performed before designating an unknown agent an "orphan" virus.

In contrast to the rapid, complete cytolysis caused by poliomyelitis viruses, growth of the Coxsackie strains was characterized by slow, patchy degeneration of the monkey kidney cells. These differences in cytopathogenicity were so clear-cut that it was possible to recognize the agents that were not poliomyelitis before serologic identification was attempted. The suitability of monkey kidney tissue for the primary isolation of most or all Coxsackie group B viruses remains to be determined. Sickles and others [5] found cytopathogenicity to be uniformly good, although the number of strains tested was small. HeLa cells cultures, on the other hand, seem to have definite limitations in this respect in that B-2 and B-4 strains are propagated very poorly. In one laboratory utilizing HeLa cells a number of B-1 and B-3 strains have been recovered, but there have been no isolations of B-2 or B-4 strains.[7] Hummeler, on the other hand, obtained primary isolations of B-2 virus in HeLa cells from 2 of 11 patients in an epidemic in a mental institution.[3b]

Ubiquity of the Coxsackie viruses has made it difficult to prove that these agents actually cause infections of the central nervous system. This etiological relationship has now been fairly well established by recovery of Coxsackie group B viruses from the spinal fluid of a number of patients with aseptic meningitis.[3] No attempts to isolate virus from the spinal fluid were made in the present study, but suggestive evidence was contributed by serologic studies. Neutralization tests with acute and convalescent serums indicated clearly that the patients were infected with Coxsackie B-2 (13 cases) or B-4 (1 case) virus. Neutralization tests were also carried out with poliomyelitis viruses, and in five cases the results provided definite evidence that there had not been a recent infection with poliomyelitis viruses. In the other nine cases the results were inconclusive in this regard.

The 13 patients whose stools yielded Coxsackie B-2 virus entered the hospital from widely scattered parts of the Seattle area. Isolation of this virus from fecal specimens, which were usually obtained a few days after admission, raises the possibility that the Coxsackie infections were acquired in the hospital in patients with aseptic meningitis due to some other cause. While this possibility cannot be definitely excluded from the data obtained, it seems unlikely in our opinion in view of the relative dates of admission to the hospital, the nature of the illness, and the failure to establish any other etiological diagnosis. Studies of hospital personnel, other patients, and family contacts, which would be necessary to settle the point, were not carried out. Clinically, the picture was that of aseptic meningitis and was indistinguishable from that of the nonparalytic patients whose fecal specimens yielded poliomyelitis viruses.

* Means not tested. † Poliomyelitis virus, type 2, isolated in later specimens.

SUMMARY

Of 66 adults admitted to King County Hospital during the summer and fall of 1954 with a clinical diagnosis of poliomyelitis, cytopathogenic agents were isolated by tissue culture (monkey kidney) from fecal specimens of 51. In 14 (27.4%) of these 51 patients, the agents isolated were not neutralized by poliomyelitis antiserums. Further study revealed that 13 of the 14 unidentified agents were Coxsackie group B viruses, type 2, and that the other was a Coxsackie B-4 strain. Neutralization tests performed on acute and convalescent serums gave clear-cut evidence of infection with the Coxsackie viruses isolated from the stools. In five of the patients, poliomyelitis antibodies were absent or present only in low titer both during and after the infection. In the other nine patients, definite conclusions could not be drawn as to

---

7. Syverton, J. T.: Personal communication to the authors.

whether the patient had had a recent infection with poliomyelitis viruses. The 14 patients infected with Coxsackie viruses ranged in age from 20 to 37 years. Ten were women, of whom four were pregnant. In addition to fever and stiff neck all had pleocytosis, but in 8 of the 14 the cerebrospinal fluid leukocyte count was below 100 per cubic millimeter. The clinical illness was that of aseptic meningitis and was indistinguishable from that observed in patients with nonparalytic cases from whom poliomyelitis viruses were recovered.

MANAGEMENT OF PURULENT MENINGITIS

James N. Etteldorf, M.D., Memphis, Tenn.

With the advent of chemotherapeutic and antibiotic agents, there has been a great decrease in mortality and morbidity resulting from infections involving the meninges. With early diagnosis and treatment, it has become possible to cure almost all patients with the more commonly occurring types of purulent meningitis; nevertheless, there continues to be a significant number of deaths attributed to this condition. Furthermore, in those who survive the ravages of this disease, a good number are left with all types of complications, many of which are serious and handicapping. Dr. Hattie Alexander[1] has attributed the failures in management of meningitis to the following causes: (1) failure to establish an early clinical diagnosis; (2) inadequate laboratory facilities for accurate and rapid identification of the etiological agent; and (3) lack of necessary discrimination in the selection and use of therapeutic agents.

The current practice of many physicians of administering chemotherapeutic and antibiotic agents singly, or in combination, early during the course of infections in which fever is a symptom has probably reduced the incidence of meningitis. However, such practice has caused an increase in those who survive with central nervous system damage. This has been attributed to inadequate therapy due to failure to select the optimal agent or failure to administer adequate dosages of the antibacterial agents for a sufficient period of time. This failure to select the proper agent, or to administer adequate dosages, may result in an undesirable outcome because the infection has not been completely obliterated and/or because a resistant strain of the infecting organism may have emerged, the more sensitive strains having been destroyed. The following discussion will outline the important diagnostic features and give a course of treatment for pediatric patients that is followed at our hospital. This treatment, which includes the management of certain complications, represents the modern trend and in our experience, as elsewhere, has given good results.

DIAGNOSIS

It is only by having a high index of suspicion of the presence of meningitis that the early diagnosis is made; therefore, great familiarity with the significant historical features, as well as the signs and symptoms, of this disease is imperative in order that the diagnosis may be established. Familiarity with these features will prompt the physician to perform a diagnostic spinal puncture when indicated. It should be emphasized that, during the neonatal period and in severely ill and debilitated infants, many of the clinical manifestations of meningitis may be lacking. Therefore, if the cause of the fever cannot be determined and if the general condition of the patient is out of proportion to the physical findings, one should look to the central nervous system for the source of trouble and perform a spinal puncture.

Signs and Symptoms.—The following signs and symptoms are among the most important: fever, anorexia, headache, vomiting, periods of increased irritability, drowsiness, high-pitched (cephalic) cry, fixed gaze, irregularity in rate and amplitude of respiration, convulsions, petechial rash (especially in meningococcic meningitis), bulging fontanel (unless infant is dehydrated), nuchal rigidity, presence of Kernig's sign, presence of Brudzinski's sign, hyperactive reflexes, strabismus, opisthotonos, coma, and paralysis.

Cerebrospinal Fluid.—The single most important diagnostic feature of this disease is the discovery of an abnormal cerebrospinal fluid. The spinal puncture must be carried out with care, and one should check for signs of increased intracranial pressure, such as bradycardia, hypertension, or papilledema, before carrying out the procedure. If signs of increased intracranial pressure are present, only a few drops of fluid should be withdrawn through a 22 gauge needle. Papilledema suggests long-standing increased intracranial pressure and may contraindicate a spinal puncture without a neurosurgical consultation. The danger lies in the possibility of herniation of the brain stem into the foramen magnum when the pressure of the spinal fluid is reduced by withdrawal of fluid.

Once the fluid is obtained, cultures should be made using the following mediums and sensitivity tests requested. 1. Chick embryo, if available, is probably the most efficient medium. 2. Brain broth in our experience has been very reliable, and cultures may be planted by permitting fluid to drop into the tube from the lumbar puncture needle. 3. Blood agar or broth should be used. 4. Dubos' or Lowenstein's medium should be used if tuberculosis is present and Sabouraud's if yeast or fungi are suspected. 5. If penicillin or sulfonamide drugs have been administered, penicillinase and *p*-aminobenzoic acid should be added to the mediums. Total and differ-

Read before the Eighth Clinical Meeting of the American Medical Association, Miami, Fla., Dec. 1, 1954.

[1] Alexander, H. E.: Advances in the Treatment of Bacterial Meningitis, in Advances in Pediatrics, vol. 5, Levine, S. Z., and others, editors, Chicago, Year Book Publishers, Inc., 1952; Guides to Optimal Therapy in Bacterial Meningitis, J. A. M. A. 152: 662 (June 20) 1953.

ential cerebrospinal fluid cell count with and without the addition of acetic acid is valuable in the differential diagnosis.

The following procedures will assist in an early identification of the etiological organism: Gram's stain; Ziehl-Neelsen's (acid-fast) stain, if tuberculous meningitis is suspected; and capsular swelling of bacteria (Neufeld's reaction) in sediment when specific antiserum is added (especially useful in identifying Hemophilus influenzae type B). Table 1 lists the more frequent, as well as some of the less common, bacteria that cause meningitis, with their staining properties and morphological characteristics. The protein level is usually elevated above 40 mg. per 100 cc. The test for sugar shows a decrease in proportion to the increase in cerebrospinal fluid cell count except for tuberculosis, which causes moderate pleocytosis.

Other Diagnostic Studies. — Additional diagnostic studies should include blood cultures with sensitivity studies; culture and stain fluid obtained from skin lesions, if petechiae or ecchymoses are present; nasopharyngeal cultures; blood cell counts; tuberculin skin test; pellicle formation of cerebrospinal fluid with acid-fast stain (the tubercle bacilli when present are concentrated in the pellicle); and India ink preparation of cerebrospinal fluid sediment for Cryptococcus neoformans, a rare cause of meningitis.

TABLE 1.—*Bacteria That Cause Meningitis*

	Staining Properties	Morphological Characteristics
Hemophilus influenzae	Gram negative	Pleomorphic rods
Meningococcus	Gram negative	Intracellular and extracellular cocci in pairs or tetrads
Pneumococcus	Gram positive	Cocci in pairs
Streptococcus	Gram positive	Cocci in chains
Micrococcus	Gram positive	Cocci in clusters
Escherichia coli	Gram negative	Rods
Pseudomonas aeruginosa (pyocyaneus)	Gram negative	Rods
Proteus	Gram negative	Rods
Salmonella Typhoid Paratyphoid A & B	Gram negative	Rods
Klebsiella pneumoniae	Gram negative	Rods
Mycobacterium tuberculosis	Acid-fast Gram positive	Rods

TREATMENT

The treatment of meningitis is divided into the following categories: supportive, antibacterial, and management of complications.

Supportive Treatment.—The patient should have bed rest and hospitalization for adequate nursing care. To control fever, aspirin should be given (1 grain [60 mg.] per year of age every four hours) for temperatures of 101 F or above; not more than 5 grains (0.32 gm.) should be given to patients under 10 years of age. A sponge bath should be given for temperature in excess of 103 F. Sedation is required for convulsions and restlessness (0.5 to 1 grain [30 to 60 mg.] of phenobarbital sodium given intramuscularly or 0.5 to 2 grains [30 to 120 mg.] of amytal sodium given intramuscularly or intravenously). Fluid therapy is usually required during the first 48 hours or longer in the following amounts: 60 cc. of 5 or 10% glucose in water per kilogram per 24 hours as slow intravenous drip; 30 cc. of M/6 sodium lactate solution per kilogram per 24 hours subcutaneously or intravenously to assure an alkaline urine when sulfonamide drugs are being used (if vomiting is absent, 5 cc. of molar sodium lactate solution per kilogram per 24 hours orally with orange juice may be substituted for parenterally administered sodium lactate); Ringer's solution by clysis as indicated in table 2; and blood or plasma (20 cc. per kilogram) in many serious and overwhelming infections in order to supply red blood cells for oxygen transport, for energy, and for passive transfer of antibodies. The use of oxygen is helpful in minimizing cerebral damage due to anoxia.

The quantity of Ringer's solution is based on the normal 24 hour requirements of salt and may be increased if the salt requirements are increased because of vomiting or adrenal failure. The Ringer's solution and 5% glucose solution may be mixed together and given either subcutaneously or intravenously. If continuous parenteral administration of fluid is required beyond two days because of vomiting, potassium chloride should be administered as indicated in table 2 and may be added in four divided doses at six hour intervals to fluid that is being administered parenterally.

Antibacterial Treatment.—The sulfonamide drugs, through their bacteriostatic action, along with penicillin, a bactericidal agent, and the new broad spectrum antibiotics, with their bacteriostatic and bactericidal actions, have made it possible to cure almost all cases of acute purulent meningitis. At least three, and sometimes four, drugs may be given simultaneously. Such combinations afford bactericidal action and reduce the likelihood of emergence of resistant strains, assuring maximal benefit to the patient. Because of the rapid development of resistant strains and the availability of new agents, use of streptomycin has been abandoned in the early treatment.

TABLE 2.—*Administration of Fluid Therapy with Ringer's Solution and Potassium Chloride*

Age	Ringer's Solution, Cc./24 Hr.	Potassium Chloride, Gm./24 Hr.
6 mo. or less	60	0.5 (7 mEq.)
6 mo. to 2 yr.	125	1.0 (14 mEq.)
2 yr. to 6 yr.	250	1 to 2 (14-27 mEq.)
6 yr. to 15 yr.	300 to 500	1 to 2 (14-27 mEq.)

Table 3 reveals the important antibacterial agents that, according to Alexander,[1] may be used either singly or in combination against the usual etiological bacteria. For the most part we agree with Alexander; however, our unpublished observations, given in parentheses, indicate instances of disagreement, except for erythromycin, which was not included by Alexander. This table shows that broad coverage is attained when a combination of sulfadiazine, penicillin, and chloramphenicol is administered. Therefore, it is our policy to administer them as outlined in table 4 by the routes designated as soon as it has been determined that the patient has acute purulent meningitis, that is, after the necessary cultures have been taken but before the etiological agent may have been identified.

If the etiological agent cannot be detected, the above treatment is continued, except that administration of aqueous procaine penicillin, 500,000 to 1,000,000 units daily, is substituted for potassium or sodium penicillin after the patient has demonstrated clinical improvement. If the etiological organisms can be positively identified on the initial studies, or later by cultures, therapy is adjusted as follows, modified by findings of sensitivity tests, and continued for a minimum of 10 days or two weeks with an afebrile period of at least 5 days and normal spinal fluid with negative cultures.

Meningococcic Meningitis: For treatment of meningococcic meningitis, administration of sulfadiazine continues to be the single most effective drug and should be continued, maintaining blood levels of 10 mg. per 100 cc. This may be accomplished by a 50% reduction in the dose given in table 4. Administration of aqueous procaine penicillin, 300,000 to 500,000 units intramuscularly once daily, may be substituted. Administration of chloramphenicol (Chloromycetin) should be discontinued.

Hemophilus Influenzae Meningitis: For treatment of Hemophilus influenzae meningitis, administration of sulfadiazine subcutaneously should be continued until tolerated orally, maintaining a blood level of 15 mg. per 100 cc. Therapy with chloramphenicol, which is the most effective single agent, should be continued. Penicillin therapy should be stopped unless unusual sensitivity is reported by the laboratory. If necessary because of undesirable effects of the above or if great sensitivity is demonstrated, the following tetracycline derivatives may be given: tetracycline (Achromycin) or oxytetracycline (Terramycin)—40 to 50 mg. per kilogram per 24 hours orally administered; 20 mg. per kilogram per 24 hours intramuscularly or intravenously administered. Immune rabbit serum should be rarely used.

TABLE 3.—*Agents Effective in Treatment of Pyogenic Meningitis* [*]

Organism	Sulfadiazine	Penicillin	Streptomycin	Chloramphenicol	Tetracycline	Polymyxin	Erythromycin [‡]

[*] Modified from Dr. H E. Alexander [1] Our unreported observations, which differ in some respect from those of Dr. Alexander, are given in parentheses.
[†] +, effective agent; 0, no significant action; —, insufficient data; ±, limited efficacy.
[‡] Not included by Alexander

Pneumococcic Meningitis: For treatment of pneumococcic meningitis, sulfadiazine therapy should be continued in dosages to achieve blood levels of 15 mg. per 100 cc. Penicillin dosage should be increased to 1,000,000 units every two or three hours; 10,000 to 25,000 units of penicillin daily in 10 cc. of isotonic sodium chloride solution may be given intrathecally for one to three days. (This procedure is highly controversial and is not a routine in our hospital.) Chloramphenicol therapy might be continued until definite clinical improvement has occurred, as Deane and co-workers [2] have observed that it renders the spinal fluid sterile in three days. When tetracycline derivatives are administered in conjunction with penicillin, a higher mortality has been reported than when the broad spectrum antibiotics are not included.[3]

Micrococcic and Streptococcic Meningitis: For treatment of micrococcic and streptococcic meningitis, penicillin therapy should be continued and the dosage increased to 1,000,000 units intramuscularly every three hours. This large dose is recommended because of the apparent increase in penicillin-resistant Micrococcus organisms that Welch [4] has observed in 12.5% of outpatients and in as many as 68% of a hospitalized population. Treatment by administration of penicillin, 10,000 units intrathecally for three days, is controversial. Sulfadiazine therapy should be continued and blood levels of 15 mg. per 100 cc. maintained. Erythromycin is an effective and dependable antibiotic against these organisms when given in doses of 8 to 10 mg. per kilogram every six hours orally or intravenously. This constitutes a large dose and is used with the hope of preventing emergence of resistant strains of Micrococcus. Tetracycline derivatives, administered orally, intramuscularly, or intravenously, should be used as in H. influenzae. After sensitivity tests have been made, chloramphenicol may be used as in H. influenzae, if the clinical course of the disease justifies its use.

Escherichia Coli Meningitis: For treatment of Escherichia coli meningitis, continue sulfadiazine therapy with blood level of 15 mg. per 100 cc.; discontinue penicillin therapy; and continue chloramphenicol therapy. Streptomycin should be given in doses of 40 mg. per kilogram per 24 hours intramuscularly and 75 mg. intrathecally daily. If the patient is sensitive, administer tetracycline derivatives as in H. influenzae. Polymyxin B should be given in doses of 5 mg. per kilogram per day in four divided doses and 5 mg. intrathecally daily for one to three days.

Meningitis Caused by Pseudomonas Aeruginosa and Proteus Organisms: Meningitis caused by Pseudomonas aeruginosa and Proteus organisms is especially resistant to treatment. Continuation of sulfadiazine therapy aids in preventing the emergence of resistant strains of Proteus. Penicillin therapy should be discontinued. Chloramphenicol therapy may be of value after sensitivity tests have been made. Polymyxin B should be used as for Esch. coli. Neomycin therapy, 400 units per kilogram intramuscularly every four hours, was used in one reported case with cure by Ditkowsky and co-workers.[5] Tetracycline derivatives usually are ineffective.

[4] Welch, H.: The Antibiotic-Resistant Staphylococci, editorial, Antibiotics & Chemother. **3**: 561, 1953.

Tuberculous Meningitis: A combination of streptomycin or isoniazid with *p*-aminosalicylic acid and at times a combination of all three agents has been used in our hospital for treatment of tuberculous meningitis and represents a modification of the Public Health Cooperative Study.[6] Streptomycin, 40 mg. per kilogram per 24 hours intramuscularly, should be given for six months or longer until the cerebrospinal fluid sugar value is normal for one week and cultures are negative. Although it is our practice to give streptomycin intrathecally, there is a trend away from this practice in many centers. Isoniazid, 8 mg. per kilogram per 24 hours orally, should be given for 6 to 12 months.[7] *p*-Aminosalicylic acid, 0.2 gm. per kilogram per 24 hours, should be given for six months to one year. Tuberculin administered intrathecally as recommended by Cairns and co-workers [8] has been unsuccessful in our hands, although they report dramatic results when it is used along with streptomycin. Use of corticotropin with antimicrobial therapy is now in the experimental stages.[9]

MANAGEMENT OF COMPLICATIONS

Subdural Effusion.—Subdural effusion occurs more frequently than is generally realized and has been reported to be present in as high as 47% [10] of the cases of purulent meningitis. The pathogenesis of these subdural collections of fluid is not completely clear. It is thought that there is damage to cerebral cells secondary to arteritis and thrombosis associated with the inflammatory process. The destroyed brain tissue and the accumulation of other inflammatory products, along with an increase in vascular permeability (arteritis), results in subdural accumulation of fluid that is high in protein. Due to the osmotic pressure of the fluid, the size of the area increases as more fluid enters and, as a result, pressure symptoms make their appearance. Furthermore, a thick inflammatory membrane may form, which in itself produces pressure.

The high incidence of this complication has made bilateral subdural taps a routine procedure in certain hospitals. It is our opinion, however, that subdural taps should be omitted in those cases in which patients are making an uncomplicated recovery and are indicated when one or more of the following signs are observed: (1) persistence of fever beyond three to five days; (2) recurrence of fever after a period of normal temperature; (3) continued increase in intracranial pressure as evidenced by a tense fontanel, enlarging head, vomiting, and convulsions; (4) focal neurological signs; and (5) any indication of unsatisfactory convalescence. Subdural taps through the fontanel or through burr holes in older children, withdrawing not more than 25 to 30 cc. at a time, should be performed at daily intervals until the formation of fluid decreases appreciably, and then at two or three day intervals. In those cases in which there is an unusual persistence of fluid beyond 10 days, surgical removal of the membrane is recommended. It is important to culture the subdural fluid and continue the administration of antibacterial agents until the infection has been eradicated.

Waterhouse-Friderichsen Syndrome.—Waterhouse-Friderichsen syndrome, a serious complication, occurs more frequently in meningococcic and hemolytic streptococcic meningitis than in the other forms. The syndrome is brought about by acute adrenal failure secondary to hemorrhage and necrosis of the glands. It is characterized by the sudden onset of shock, prostration, and cyanosis. The pulse is fast and feeble, and the blood pressure is low. The skin is cold and clammy with petechiae and ecchymotic areas. Heroic therapeutic measures are required and include prompt intravenous administration of 1,000,000 units of aqueous penicillin and 0.15 gm. per kilogram of sulfadiazine sodium, to be followed by the schedule as outlined above. It is essential that adequate 10% glucose in water and at least twice the recommended quantity of Ringer's solution be given intravenously. Blood transfusions are imperative in the management of this syndrome. In addition, 50 to 100 mg. of hydrocortisone should be given intravenously,[11] followed by a similar dose intramuscularly every two hours for two or three doses and then 100 mg. once or twice daily for three to five days, depending on clinical course. Hydrocortisone should be withdrawn gradually over a period of five to seven days. Arterenol (nor-epinephrine), 4 cc. of 1:1,000 solution in 1,000 cc.

TABLE 4.—*Administration of Agents Effective in Treatment of Purulent Meningitis*

Drug	Dosage and Administration
Sulfadiazine sodium as a 5% solution	3 cc./kg. (0.15 gm./kg.) immediately subcutaneously, then 6 cc./kg. (0.30 gm./kg.) in 4 doses per 24 hr.
Sulfadiazine	Similar dosage when tolerated orally
Penicillin, sodium or potassium	500,000 units I.M. immediately and every 3 hr.
Chloramphenicol	40 mg./kg. I.M. or I.V. immediately 50 mg./kg. orally immediately 50 mg./kg. I.M. or I.V. daily, 4 divided doses 100 mg./kg. orally daily

of saline given intravenously for approximately 24 hours at a rate sufficient to maintain a satisfactory response, has proved valuable in combating peripheral circulatory collapse.

Other Complications.—Other complications such as convulsive disorders, emotional disturbances, behavior problems, and mental deficiency, which may follow, especially in serious cases, should be treated as they occur.

CONCLUSIONS

If the diagnosis of meningitis is established early and followed promptly by an intense and adequate therapeutic and supportive treatment, the mortality and undesirable sequelae from this disease will be minimized. Early recognition of the complications followed by energetic treatment also has an important place in the management of this disease.

HYPNOTISM IN PREGNANCY AND LABOR

Sol T. DeLee, M.D., Chicago

The manifold phenomena of hypnosis are being intensely studied today by physicians, surgeons, dentists and clinical psychologists to build a new science from the foundation of an ancient art. With psychoanalysis and psychosomatic medicine still meeting with some resistance by the medical profession, hypnotism, quite naturally, is receiving an even more critical examination. Yet, it is in relation to these specialties that it is of the greatest therapeutic value. Hypnotism, at the present time, is also receiving considerable studied application in obstetrics. The purpose of this presentation, therefore, is to evaluate and discuss its use, advantages, and disadvantages in obstetrics in selected patients and to briefly review its history in medicine. Our knowledge of the motivations behind human behavior is still inadequate to explain all of the complexities of mental dysfunction. The lack of understanding of the phenomena of hypnosis strongly emphasizes our deficiencies in this regard. Plainly, this invites antagonism to the use of hypnosis, because it threatens our complacency concerning accepted beliefs and contributes to doubts that have relegated hypnosis to the background. Extravagant and unfounded claims by some of its ardent proponents, plus sensationalism in its application in the field of entertainment, account for further opposition.

BACKGROUND

Since its earliest use by the ancients, hypnotism has always been erroneously associated with supernatural powers. This is not surprising, as a study of its history points up its connection with the bizarre, mysterious, and unknown as they relate to the unexplored regions of the mind. From antiquity, hypnotism has played a role in religion and medicine, and the phenomena produced by medicine men, witch doctors, and priests have always been ascribed to miracles performed by the gods. In Egypt there were "sleep temples," and a papyrus more than 3,000 years old describes hypnosis much as it is used today. In Greece, the sick were treated and cured through hypnosis by religious leaders. The Hindu fakir, the South Pacific fire dancer, and the Indian yogi of today use self-induced hypnotic analgesia to make their feats possible.

The therapeutic use of hypnosis was revived late in the 18th century, when a Catholic priest, Father Gassner, obtained hundreds of "faith cures" through its methods. Franz Mesmer of Vienna, impressed by Father Gassner's results, employed the art during the early 19th century and developed a large following in the medical profession. Many authentic cures by "magnetism" were reported. Mesmer's methods, however, as well as those of his followers, overlooked the role of suggestion in alleviating disease and suffering. Unfortunately too, his methods were spectacular and frequently bordered on charlatanism. The latter stigma, along with the inexplicable phenomena, eventually alienated his colleagues, and Mesmer ultimately was ostracized by the medical profession, a fate subsequently known to many men who pursued their interest in this field. James Braid, a Scotch physician, merits the title of "father of modern hypnotism," although Liebeault, a 19th century French physician, is often given the credit. Liebeault coined the terms hypnotism and hypnosis and wrote many papers, as well as an authoritative book on the subject. Liebeault founded the Nancy school and developed the theory that suggestion was the key to hypnosis. The first surgical operations using hypnosis were performed by Recamier in 1821. Cloquet reported his use of hypnotic anesthesia in surgery to the French Academy of Medicine in 1829. In America at about the same time, Wheeler did a nasal polypectomy employing hypnosis, its first such use in this country.

The new science grew, and, in 1840, James Esdaile, an English surgeon practicing in India, reported thousands of operations using hypnosis; more than 300 of these involving major surgical procedures, such as limb amputations. His book describing these operations is a library treasure today. Since then, particularly in the last two decades, numerous authoritative articles have appeared in the scientific literature, describing the anesthetic applications of hypnosis in obstetric and surgical procedures. Although slowly accepted, hypnotism emerged as a science around 1890, when Bernheim, a French physician, perfected techniques that are still used for induction of hypnosis. He, like Liebeault, recognized that suggestion was the basis for hypnosis, and his unimpeachable reputation added to the growth of the science. This form of therapy began to come into its own, and many recognized scientists, including Charcot,

---

Assistant Clinical Professor, Obstetrics and Gynecology, University of Illinois Medical School, and Attending Physician, Chicago Maternity Center.

Freud, Pavlov, Babinski, and Janet, accepted its validity. In America, Phineas Quimby, a leading practitioner, became historically famous by treating Mary Baker Eddy for a neurotic condition. She was enthusiastic about his methods but denied that hypnosis had played a role in the results. Shortly thereafter, she evolved her own theory of healing, known today as Christian Science. For a complete history of Christian Science and its relation to hypnosis, the reader is referred to Bromberg.[1]

Hypnotism currently interests many psychiatrists, anesthesiologists, obstetricians, gynecologists, and dentists. Today's literature is filled with impartial investigations of hypnotherapy for psychosomatic conditions. The recent war demonstrated the value of hypnoanalysis in combat fatigue and other war neuroses. Its success has helped considerably in reducing the disdain, fear, and apprehension that formerly plagued this valuable entity. No longer shrouded in mysticism, it has emerged as an established aid to depth psychology. Hypnotism (from the Greek "hypnos" meaning sleep) is a method of inducing relaxation, during which susceptibility to suggestion is increased. An all-inclusive definition of suggestion describes it as an idea that the person accepts uncritically, which thereby enables him to initiate appropriate behavior. The degree of suggestibility to hypnosis depends on the depth of the various stages. Some authorities describe as many as nine stages; others five or six. Three arbitrary hypnotic stages, however, which frequently overlap, are generally recognized; namely, light, medium, and deep. These are equivalent to the lethargic, cataleptic, and somnambulistic stages. They do not include a condition of a slight degree of suggestibility, which is termed hypnoidal, wherein relaxation and drowsiness are present.

For practical purposes, only the light and deep stages will be considered here, although it must be emphasized that this is most inadequate for experimental or scientific investigation. The light stage is characterized by eye and limb catalepsy, lassitude, and heeding of simple posthypnotic suggestions, as well as partial analgesia and anesthesia. During deep somnambulism, there is marked responsiveness to posthypnotic suggestions, complete analgesia, anesthesia, and posthypnotic amnesia. Although analgesia means the absence of sensibility to pain and anesthesia the loss of sensory perception, this author, as well as those herein referred to, use the term anesthesia more broadly to include also the absence of pain sensitivity. In somnambulism too, one can produce recall of memory and age regression, as well as both positive and negative sensory hallucinations. The foregoing phenomena are the only ones of significance in our present study. Many others, important to the clinical psychologist and psychiatrist, are omitted. Individual reactions vary greatly. The objective symptoms of the deep hypnotic state may be evidenced in a person in a medium or light trance, and symptoms of the light stage can occur or may be absent in a person deeply hypnotized.

ADVANTAGES

The late J. B. DeLee[2] recognized early that profound relaxation during delivery in some patients could best be obtained by hypnosis. He wrote, "The only anesthetic without danger is hypnotism. . . . I am irked when I see my colleagues neglect to avail themselves of this harmless and potent remedy." The advantages of hypnotism in obstetrics are many and may be enumerated as follows: 1. Because the patient is treated in an unusual and special manner and because suggestibility is present, she is likely to have a more pleasant pregnancy, free from the ordinary discomforts associated with this condition, such as nausea, pressure, and cramps. 2. Fear, pain, and apprehension before and after labor are eliminated. 3. It is possible to allow the mother to experience the sensations of childbirth without attendant pain. 4. Uterine contractions often can be either accelerated or retarded by suggestion. 5. Blood loss is considerably reduced owing to vasoconstriction of the capillaries. 6. Elimination of pain decreases shock and facilitates recovery. 7. The responsive patient cooperates more fully, this being particularly valuable during the expulsive stage. 8. There are no undesirable postoperative effects from hypnosis as with most other anesthetics. 9. In premature deliveries hypnosis is of especial advantage because it reduces fetal anoxia. 10. Hypnosis raises resistance to fatigue by about 20%, minimizing maternal exhaustion. 11. Hypnosis is indicated in persons who are allergic to anesthetic agents. 12. Chemical anesthesia, especially ether, depresses uterine activity and interferes with the normal mechanism of labor; this is not so with hypnoanesthesia. 13. The first stage of labor can be reduced. According to a controlled series by Abramson and Heron[3] the first stage of labor was reduced by two hours; in a controlled series by Michael,[4] the first stage of labor was reduced by approximately four hours in primiparas and by about 15 minutes in multiparas. Michael further points out that the second stage of labor in his series was reduced by one hour in primiparas; in multiparas the time was only insignificantly different.

DISADVANTAGES AND DANGERS

Many physicians familiar with the potentialities of hypnosis are enthusiastic about its results in selected patients. Previous publications[5] note that its use in obstetrics can be most effective despite certain objections and limitations. It has been estimated that as high as 90% of normal persons can be hypnotized to some degree. Success depends largely on the skill of the operator and the inherent susceptibility of the patient. In spite of the high percentage of susceptible persons, surgical anesthesia can be induced in only about one out of four patients, and even in these it may not be complete. This limitation, of course, is a valid objection to its use as an anesthetic agent. The time necessary to achieve rapport and a satisfactory trance depth suitable for surgery is another disadvantage. In parturition, with the patient's knowledge and permission, a trained hypnotherapist should be available throughout the entire labor, unless autohypnosis has been induced through posthypnotic suggestion. The presence of the operator for a prolonged period makes an additional expense for the patient. This objection will be largely eliminated as hypnoanesthesia grows in use and more trained personnel are available.

In a deeply disturbed person, either psychotic or borderline psychotic, hypnosis is contraindicated, except by one also trained in dynamic psychiatry. There is little possibility, however, that hypnosis can precipitate a psychotic condition, but the likelihood that it might be held responsible is much greater. Psychotics are difficult, almost impossible, to hypnotize, but even if they proved susceptible, the dangers would be minimal. Such patients, of course, should not be treated by the general practitioner. Some psychiatrists and others contend that hypnosis fosters extreme dependency. For example, Jacobson[6] favors relaxation methods in labor and Read's simplified techniques but believes that psychiatric suggestion and hypnoidal states in obstetrics are unreliable—they may cloud symptoms and produce analgesia in only about 10%—and unsuitable for the average patient. Jacobson further states that hypnosis tends to increase personal dependence. This may be true, but a strong bond of dependency exists in every doctor-patient relationship, especially between obstetrician and patient. This dependency, however, is only temporary and of no permanent importance, although it can be used advantageously at the time to establish greater confidence in the obstetrician. As in psychotherapy, this dependency serves to bind the patient in treatment during the initial interviews when rapport is not too firmly established. Later, the reasons for the dependency can be worked through and dissolved.

Cultural attitudes still exist toward hypnotism that undoubtedly cause many physicians to have an unreasonable aversion to its practice and clinical application. Fear of failure influences many others in not employing it. Still others, realizing the clinical advantages of hypnosis, do not like to assume the role of hypnotherapist or operator because of fear of being stigmatized. The delicacy one must apply in dealing with hypnotism is another objection to its use in private practice and points up the fact that until its value is more fully understood and accepted, it is a method best accepted by the doctor at the patient's request. These objections can be eradicated if patients understand that the physician is only trying to teach them how to assume healthy attitudes and that there are no magic powers invested in him.

PREPARATION

When a gravida decides to have her baby under hypnosis, one must empirically determine her responsiveness. Of course, every patient is not susceptible to deep hypnosis, and the therapist must establish her potentialities before the onset of labor. Rapport is essential, this being defined as the harmonious relationship between subject and therapist. Once the subject cooperates in carrying out a suggestion, rapport is definitely established. Although no less time-consuming than preparing patients for natural childbirth, training for hypnosis is not elaborate. Patients do not have to read, exercise, or attend prenatal training classes. After inducing hypnosis several times before labor, and during each session giving posthypnotic suggestions that labor will be painless, one can easily raise the pain threshold. Repeated conditioning readily enables the patient to reach the deeper stages of hypnosis. The patient is told that she will look forward to her pregnancy and confinement with a feeling of joy and happiness, instead of dread and apprehension. The more these posthypnotic suggestions are repeated, the more effective they become. She is repeatedly told that she will promptly fall into a deep hypnotic state in response to a given command at any time. Suggestions must be made in a dignified, firm manner, and it is imperative that the gravida maintain complete confidence in her physician and/or therapist and the method at all times. After adequate preparation, she can be put into a somnambulistic state in a matter of seconds.

Response to posthypnotic suggestions and production of amnesia and anesthesia during the prenatal training period give the indication that the patient is ready for all the stages of labor. An Allis clamp or sterile needle may be used for testing the depth of anesthesia. Complete anesthesia during parturition is often accompanied by amnesia, and these are attainable by command. Amnesia for part or all of the labor and delivery can be induced or removed at the suggestion of the therapist, according to the previously expressed wishes of the patient. Ideally, conditioning should begin during the third or fourth month of pregnancy. The patient should be hypnotized two or three times a month until the stage of deep hypnosis is reached. Just how many visits a patient will require before one can feel confident of satisfactory anesthesia is uncertain; it can be 1, 20, or even more. Usually, if after 10 sessions anesthesia is not obtained, the outlook is poor. Patients must be informed in advance of the possible time element so that early discouragement is avoided. Hypnosis cannot be induced in some patients, owing either to insusceptibility or a lack of rapport between the therapist and that particular individual. There may also be an inconsistency of response from time to time in the same individual.

Many excellent hypnotic techniques are described, and several authoritative books are available on this subject.[7] Here it should be emphasized that physicians desiring instruction in hypnotism should seek it from reputable and qualified scientists, rather than from lay practitioners not conversant with its medical applications. If a trained hypnotherapist is to induce the hypnosis rather than the obstetrician himself, the patient will visit the therapist as often as is necessary until late in pregnancy, at which time, or whenever the maximum degree of hypnosis has been reached, a transference of control may be affected; that is, unless it has been prearranged between the patient and obstetrician that the therapist is to be with the patient throughout her labor. A good somnambulist, through posthypnotic suggestion, is capable of inducing self-hypnosis and by autosuggestion can eliminate the fear, tension, and pain associated with childbirth.

LABOR

When labor begins, as determined by the presence of regular contractions at intervals of five to six minutes lasting 30 seconds or more, or by the existence of a dilating cervix, regardless of the character of the contractions, the patient should be hospitalized and placed in a hypnotic state. This can be done by the physician personally, or by his speaking to her over the telephone, or by an assistant, such as a nurse, presenting her with a written order—all depending on the prenatal training and conditioning. Later, the hypnotist's presence is necessary to prolong the trance and prevent it from lapsing into natural sleep from which the patient could awaken with actual distress. Suggestions are given for complete anesthesia and usually amnesia. The patient appears to be relaxed and asleep, even during the height of labor and the delivery phase. As previously stated, it is possible for the patient to experience some of the sensations of childbirth, yet feel no discomfort. Michael [8] states that "The question of a disturbance in the normal mother-child relationship has been raised, but it is felt that this relationship, rather than being impaired, is actually enhanced, as the mother retains no unpleasant memories of the childbirth." Contractions can be felt as a tenseness of the abdomen and the bearing-down reflex as slight perineal pressure. Participation, as well as full knowledge of all occurrences, can be effected upon command, or amnesia (partial or total) can be induced. It is thus that a spontaneous or operative delivery is managed, whether the operative procedure be a major or minor one.

COMMENT

For centuries research has been unsuccessful in explaining the true mechanism of hypnosis and its associated psychological and physiological phenomena. That there is no acceptable theory of hypnosis is due to the fact that most investigators attempt to explain trance induction and its phenomena rather than the actual hypnotic state per se. It has been postulated in the literature that the hypnotic state was once used in primitive men as a defense mechanism to ward off fear or danger. Some believe that the hypnotic state in susceptible persons is, in reality, a throwback to the state of catalepsy, so commonly observed in frightened animals when they "freeze" to the landscape to escape detection. The presence of a fully developed cortex now makes such instinctual defense mechanisms unnecessary; however, this atavistic tendency is closer to the surface in good subjects than in those who are not readily hypnotizable.

Schneck,[9] likewise, in terms of its basic ingredient views the hypnotic state as that condition represented by the most primitive form of psychophysiological awareness of individual-environmental differentiation that can be obtained among living organisms. He believes that the bringing to the fore of this most primitive state and its retention to some degree exists among all biological forms. Howarth [10] agrees that "hypnosis has been present since the days when living matter originated in the primeval mud." He contends that hypnosis results whenever the organism reacts to stimuli or "input" suggestions from the environment. He believes that clinical hypnosis is a special form of suggestibility, based mainly on the ability of the higher neural centers to interpret semantic representations. Any stimulus is thus a suggestion from the environment, but whether it is acted upon depends upon a previously established sensory order or, to use a more common term, "the meaning of things." Hence, hypnosis is essentially the process of creating attitudes suitable for the acceptance of suggestion.

These theories certainly do not irrefutably answer all of the questions. Some refer to hypnosis as a form of sleep, yet the hypnotic state is not natural sleep nor is it unconsciousness. Brain waves, reflexes, galvanic skin reactions, cerebral circulation, and blood pressure readings in hypnosis are identical to the normal state and differ from true sleep in the same person. Our most sensitive investigative techniques have not produced the answers. There are many other theories as to the nature of hypnosis, and the literature is boundless on the subject. The practical question is whether or not it is useful, and if so, why not add it to our armamentarium?

There is no doubt that the anticipation of pain is an important factor in the intensity with which it is felt. Such expectation and fear can be effectively relieved with suggestions given during even light hypnosis. Common sense discussion and education can have the same effect, although these are more time-consuming and often less effective. The same arguments that favor a natural childbirth program make the use of hypnosis desirable. In fact, this author,[11] whose experience with hypnosis in obstetrics is moderately limited, concurs in the conviction of Mandy [12] and others that some successful natural childbirth patients have been hypnotized to a degree; they have reached at least a light and, in some instances, a medium trance not dissimilar to a waking hypnosis without self-awareness and usually without the knowledge of the doctor. Most patients under Read's system demonstrate at least some of these phenomena. Whether natural childbirth is by means of hypnosis or not is unimportant here. What is pertinent is the similarity of advantages and results. With education through reading, class instruction, exercises, and suggestive therapy, natural childbirth patients lose anxiety and fear and much discomfort both in pregnancy and labor. They enjoy their experiences and are very cooperative and relaxed patients. Of course, many natural childbirth patients have pain during the last part of the first stage and entire second stage but certainly less than those unprepared. Furthermore, they require less use of analgesic and anesthetic agents. The same can be said of patients who train for hypnosis. They are more cooperative and require fewer, if any drugs.

SUMMARY AND CONCLUSIONS

During the past decade, as a result of the interest of the medical profession in suggestive relaxation methods for painless childbirth, a marked increase in the scientific applications of hypnosis has become apparent. It has been a belated but welcome recognition of the usefulness of hypnoanesthesia, either as an anesthetic agent or as an adjunct to chemoanesthesia. Hypnosis in parturition is far from a panacea nor will it ever supplant chemoanesthetic agents. Nevertheless, its applications are growing daily, and it is proving a powerful ally in alleviating other functional conditions in obstetrics and gynecology; this is also true in other clinical fields. Seminars by qualified scientists to teach all aspects of clinical hypnosis are increasing rapidly, and the British Medical Association recently recommended that all physicians be grounded in the basic principles of hypnotherapy. It must be emphasized that in order to successfully employ hypnotic techniques for psychotherapy, one must be oriented or trained in psychodynamics. More active participation and education in hypnotic methodology will help dispel misunderstanding and apprehension among the laity. Thus, if judiciously employed, another valuable technique will be available to more physicians who wish to mitigate the pain of parturition.

A NEW METHOD OF MANUAL ARTIFICIAL RESPIRATION FOR INFANTS AND SMALL CHILDREN

Capt. Harold J. Rickard (MC), U. S. N.

Present Methods of Resuscitation

It has been written, "One of the serious indictments of modern specialized medicine is the lack of knowledge of many doctors of how to perform effective artificial respiration in emergency situations. For example, is it not true that many times the doctor is embarrassed in the presence of a crowd around a drowned or electrocuted person because he realizes that he is less competent to perform a life-saving act than the Boy or Girl Scout, the policeman or the fireman who stands watching his fumbling efforts at resuscitation?" [1]

If the above quotation, written by prominent physicians, approximates the truth, and I personally have reason to believe that it does, we might properly ask what fumbling efforts at resuscitation, if any, are being made by the average lay person and why?

It is my candid opinion, based upon more than 35 years of practical experience in the resuscitation field, that the indictment is not due so much to the lack of knowledge but rather to the lack of practice and the relative infrequency of opportunities for practical application. The act of giving effective artificial respiration in emergency situations, in fact in all situations involving asphyxia, is developed in two distinct stages. The theoretical stage can be learned by lectures and informal talks on the subject. The practical stage can be obtained by experience and practice only. It cannot be taught; it must be acquired. These facts do not seem to be well understood by the general public. Hence the physician in emergency situations, in public, is more apt to gain public criticism for his honest, though possibly fumbling, efforts than the rescue squads of fire departments, police, and Boy Scouts, who devote much available time and effort in practice and most certainly have more opportunities for practical application of the art of resuscitation, both manual and mechanical, than the average physician. Regardless of whether this constitutes a valid excuse for the average physician, in the eyes of the public it still remains a fact, and the average lay person would seem to be much worse off in this respect due to his or her lack of theoretical knowledge. Consequently, any effective method or technique of a resuscitative nature should, insofar as possible, eliminate or alleviate these chances for error by the average physician and layman. The vital and effective components should be as nearly automatic as it is humanly possible to make them.

The successful and widespread use of the modern mechanical resuscitator has been mainly due to the fact that these important components are provided for in a mechanical way. Aspiration and a mechanical airway are provided not only to obtain but also to maintain an unobstructed and adequate airway. Pressures are controlled and applied by automatic cycling in a constant and rhythmic rate with minimum variation throughout the entire procedure.

Finally, the manual effort expended by the operator is negligible. At present there is practically unanimous agreement that these units are safe and effective. However, the fact remains, as has been pointed out many times in the past, that they are usually not available to the average doctor or layman when an emergency arises. On the other hand, if it were possible to utilize and duplicate several of the most important components in a manual method in which extra equipment was not necessary, the results would be not only safe and effective but also extremely adaptable to resuscitative efforts in infants and small children.

HISTORY OF ARTIFICIAL RESPIRATION

When one digests the literature dealing with the history of artificial respiration, one important thing stands out glaringly, and that is the apparent reluctance of the medical profession as a whole to take the lead in this most important subject. It is true that many members of the profession made notable contributions in this field in the past, as individuals, but it was not until within the past several years that a concerted effort was made by the entire profession. This effort was brought about primarily by the vital interest of the members of the medical profession serving in the armed forces and by association with civilian medical groups. The results of these conferences and of laboratory and clinical experimental work culminated in a proposed change from the

The opinions and/or assertions contained herein are the private ones of the writer and are not to be construed as official or reflecting the views of the Navy Department or the naval service at large.

[1] Cullen, S. C., and Gross, E. G.: Manual of Medical Emergencies, Chicago, Year Book Publishers, Inc., 1950.

Schafer (prone pressure) method to that of the Holger Nielsen (arm lift–back pressure) method, which is a modification of the Nielsen technique used successfully for 20 years in the Scandinavian countries. The proposed change was officially approved and adopted by practically all major organizations vitally interested in this subject. This included the armed forces, the American National Red Cross, the Federal Civil Defense Administration, the Public Health Service, the Bureau of Mines, the Boy Scouts and Girl Scouts of America, the American Telephone and Telegraph Company, the Council on Physical Medicine and Rehabilitation of the American Medical Association, and others.[2]

It should be pointed out that the arm lift–back pressure method was proposed, approved, and adopted as the preferred method but that modifications and even other methods, such as the Silvester (arm lift–chest pressure) method, may at times and in certain complicated cases have to be utilized. These situations could occur in cases of injury and advanced pregnancies.

APPLICATION OF EXISTING METHODS TO INFANTS AND SMALL CHILDREN

There should be no question, after the excellent reports by many well-known authorities, of the efficiency of the arm lift–back pressure method on all humans. However, I seriously question the safety factor with which this method may be efficiently applied to infants and small children, for the most part by willing but comparatively inexperienced hands and under the mental stress of a human catastrophe. In the presence of such emergency situations, excitement and fear of a possible fatal result is bound to prevail, and under such circumstances vital errors usually are committed. Probably the outstanding error most frequently committed is that of inadvertently exerting undue pressure on the rib cage in accomplishing the expiratory phase. Experienced personnel realize that such pressure is rather difficult to control if the maneuver is carried out according to standard instructions. Actually, the operator is not or should not be exerting pressure by pressing but rather by keeping the elbows stiff and using a rocking maneuver of his body, thus utilizing his upper body weight to effect the pressure that performs the expiratory phase. Consequently, as has happened in the past, even in experienced hands, ribs have been fractured accidentally, and in a number of cases lung tissue has been punctured. These complications have occurred in the past when the prone pressure method was the accepted one of preference and the pressure, for the most part, was supposedly applied in the region of the floating ribs, which anatomically have a variable amount of give over and above that usually possessed by a fixed rib. In contrast, it should be noted that, with the presently accepted arm lift–back pressure method, this pressure is exerted entirely on a fixed rib area that should be more vulnerable. In a final analysis it should be apparent that the greater the disproporation in the size and weight of the operator with that of the subject the more probable is the chance of accidental injury to the subject. Likewise, an overzealous operator, especially a lay person with limited practical experience, could perform in an unsafe manner, while his counterpart through knowledge and fear of the consequence of injury could perform in an overcautious and ineffective manner. In spite of these possibilities by inexperienced or experienced operators, the fact remains that in cases of injury, the arm lift–back pressure method, with the modifications as recommended, is the safest, most practical, and most effective method of manual artificial respiration in the majority of cases of adult asphyxiation.

The resuscitative span in the human species must necessarily extend from birth through infancy and early childhood and from young and older adults on into the aged groups to be all-inclusive. This thought was expressed, quite pointedly, by Dr. Julius H. Comroe Jr., who in September, 1950, while presiding over one of the sessions at a conference on artificial respiration held at the medical division, Army Chemical Center, Maryland, closed the discussion with several general remarks including: "From the various studies that have been reported here this morning possibly one has to find out whether the findings hold in small children, infants, and the aged." [3]

It is difficult to believe that the importance of this remark was completely missed by all in attendance at this conference, since many outstanding contributors to the field of artificial resuscitation were in the audience. However, I have no knowledge of any experimental work that has been done nor have I been able to locate any published experimental data concerning manual resuscitation in infants, small children, and the aged. It will be assumed that those who may have contemplated any such experimental work in these groups were deterred in their efforts by the same reasons that I have been deterred: 1. It would be very difficult, if not impossible, to find families who would volunteer infants and small children for any such experimental work, regardless of how safe the procedures were intended to be. 2. The courts would frown upon any such experimental work on minors. 3. Last, but most important, the workers themselves would be very reluctant to deliberately place infants and small children in a state of apnea, because of the inherent risk involved. In this respect it will be recalled that the subjects used by Gordon and co-workers [4] in their experimental work were normal human adults who volunteered their services and who were given curare and anesthetized.[5]

FOUR RESUSCITATIVE AGE GROUPS

Because of the unavailability of any such data at present and the high improbability of any being obtained in the near future, it becomes necessary for the purpose of this paper to assume that in a comparable way the experimental data obtained from the excellent work done on normal adults will be essentially applicable to infants and small children. It seems only reasonable to expect that these data on tidal exchange and venous return are applicable to infants and small children in a comparable way when their size and anatomic structures are compared with those of an adult. It has already been mentioned that artificial respiration must be applicable to all ages of the human species, and I will for convenience divide them into four approximate resuscitative age groups: (1) newborn infants, (2) infants and small children, (3) adults, and (4) the aged. The person's sex would not appear to have any direct bearing on the over-all subject of resuscitation with the possible exception of advanced pregnancy. In such cases it will be necessary to modify the procedure accordingly.

Resuscitation of Newborn Infants.—Newborn infants will be mentioned only for completeness, as there is a more or less universal tendency to treat resuscitation of this group separately and as a special problem. The etiological factors are usually quite different and the emergencies occur at a time and place where it is basically not necessary to resort to manual methods of artificial respiration.

Resuscitation of Adults.—Resuscitation of adults is covered adequately by the arm lift–back pressure method with modifications in cases of injury and the arm lift–chest pressure method in cases of advanced pregnancy where the supine position would not seriously interfere with obtaining and maintaining an adequate airway.

Resuscitation of the Aged.—In the absence of any adverse experimental data in the aged group and in view of the practical results obtained in the past, it is felt that the same methods as applied to the adult group would be safe and efficient, provided cognizance is taken of any marked infirmities.

Resuscitation of Infants and Small Children.—The group infants and small children has purposely been changed to last for discussion because basically it is the subject and purpose of this paper. Before I go into the discussion and proposal of a new method, the question might very well be asked, what is or has been wrong with the old method? The truth of the matter is that all of the proposed methods of the past and present have serious shortcomings, from a practical standpoint, in infants and small children, and in a final analysis it is the practical application that determines the results in this group as well as in the others. These methods could not be considered safe, neither could they be deemed efficient. These are not simply words of condemnation; they are practical facts that can be attested to by individuals who have gained recognition in the practical application of resuscitation and as qualified operators. Probably among the outstanding groups in this category are the so-called rescue squads who are usually a part of the fire department of large and small municipalities. They are the groups who respond to most of our asphyxial emergencies and consequently receive most of the opportunities for practical application and evaluation of resuscitation methods, both manual and mechanical. However, these groups are becoming more and more dependent upon their excellent mechanical equipment rather than upon manual methods. Furthermore, the lapse in time of arrival, which is the most important single element in cases of asphyxiation, is not conducive to a recovery. Someone on the scene must be prepared to act intelligently, safely, efficiently, and, most important, immediately. Seconds are paramount, and they pass by very rapidly. This is not time to seek aid but rather the time to give it.

SPECIAL CONSIDERATIONS FOR INFANTS AND SMALL CHILDREN

In reviewing numerous textbooks on pediatrics, in respect to the weights and sizes of infants and small children included in this age group and in which such a method would have practical application, some general conclusions may be drawn. In a general way, one may conclude that such a method must be applicable in practice to infants and small children from the time they are taken home from the hospital weighing approximately 7 to 8 lb. (3,175.14 to 3,628.73 gm.) with an average over-all length of 20 to 21 in. (51 to 53 cm.) until they reach the age of 1½ to 2 years, weighing approximately 24 to 28 lb. (10.9 to 12.7 kg.) with an average over-all length of 31 to 33 in. (79 to 84 cm.).

This age group has been frequently and aptly referred to as children of the helpless age and children of the age of exploration. They constitute not only a very large group but also a group in which many asphyxial emergencies occur with, unfortunately, too many fatal results. According to the present trend toward increased birth rates, this group may likewise be expected to expand in the immediate future with a probable increase in asphyxial emergencies and deaths. Accounts in the daily newspapers throughout the country, as well as the syndicated press, would imply that this age group is exposed to more hazards that frequently lead to asphyxial death than any other group. If this is true, it is likewise true that many of these hazards are the result of the inherent human weaknesses to which we as adults are all subject. For example: The young mother didn't understand that a helpless infant could smother in a nice fluffy pillow or strangle in a crib or that the child left in the bath tub while she answered the door bell or telephone would drown in such a short time. The father never suspected that the neighbor's child could enter an unlocked and open gate to an otherwise well-fenced swimming pool and drown in the short time it would take him to answer the telephone. The corner grocery was just across the street, but the unguarded electric socket was closer than that to a mother's young explorer at the tender age of 1½ years. Thousands of such cases are known and many thousands more will, no doubt, be repeated. They serve to emphasize several important facts, namely, that this age group quite emphatically represents the helpless and exploratory children who will get into serious asphyxial situations and that, when inadequate or tardy precautionary measures are taken by adults in the name of safety, they too frequently result in a false sense of security. Most safety measures are designed to be absolute. However, when they are controlled by humans, many tend to become relative and accidents do occur. This fact has been proved too often to be ignored, and consequently what would seem to be the inevitable, especially in cases of asphyxiation in this age group, must be prepared for in advance. Time does not permit the calling of a rescue squad nor searching for a neighbor who knows "how." You are on the spot in more ways than one and what you know and do immediately will determine, to a large extent, what the ultimate result will be. Should help arrive, in the form of a rescue squad, their results will likewise depend to a large extent upon what you have done. Time lost through inactivity at the beginning cannot be regained at a later period. These facts have been reconfirmed just recently by interviews with some 50 well-informed practical operators in charge of well-equipped professional rescue squads.

After a general discussion of artificial respiration, both manual and mechanical, a number of questions were asked in reference to artificial respiration in infants and small children. The answers led to the following unanimous conclusions: 1. No safe and efficient standard method of manual artificial respiration is available. Such a method, if available, would have wide application almost daily. 2. More and more reliance is being placed on mechanical resuscitators. The results, however, are not generally favorable unless some manual effort has been made immediately prior to their arrival. 3. Mechanical resuscitators cannot be used effectively in the average case of submersion unless the patient has been rendered essentially dry by some manual method, and manual modifications currently in use are not generally effective. 4. One of the most difficult problems is to maintain an unobstructed airway without resorting to the use of a mechanical one (if available) with frequent use of the aspirator and interrupted resuscitation. 5. The arm lift–back pressure method has improved the results obtained with adults, but it is potentially dangerous or inefficient in this age group. 6. According to the records of these operators, asphyxial emergencies in this group are definitely on the increase, and this increase is due mainly to cases of submersion. 7. Present and proposed legislation requiring fenced in or covered private swimming pools is a step in the right direction, but you cannot legislate against human weaknesses and chances of error. 8. Finally, not only the operators but the general public must have some safe and efficient standard manual method available and be able to use it immediately before any improvement in asphyxial fatality rates in this age group may be expected or realized. It was also pointed out that, in order to develop public interest and participation in learning such a method, it could be introduced and made a part of the national civil defense program in respect to respiratory paralysis due to nerve gases. Generally, parents are more concerned about what they can do for their children than they are about their own safety.

SHORTCOMINGS IN PRESENT METHODS OF RESUSCITATION

I have mentioned serious shortcomings in present methods for this age group. Let us examine them in the order in which they appear and in the order of their importance. It has been stated previously that any practical and efficient method of manual or mechanical artificial respiration must provide not only artificial respiration but also artificial circulation, or at least enhance pulmonic circulation and venous return to the heart. This can best be accomplished by an active expiratory phase and an active inspiratory phase commonly referred to as a push-pull, rocking, or, in the case of mechanical resuscitators, alternating positive-negative action. However, before any of these methods may be effectively utilized, it is absolutely mandatory that an unobstructed and adequate airway be established and, I hasten to add, maintained. Many manual methods have been proposed; however, only those considered to be efficacious under practical circumstances and applicable to individuals in this age group will be discussed as to serious shortcomings in the different components comprising the resuscitative effort or technique.

Position.—There is little or no discussion necessary concerning position of the victim, since it is a universally accepted fact that a prone position is far superior to that of a supine position in cases of asphyxia in general. It is conducive to the expulsion of oral-nasal secretions and vomitus, and a moderately "head down" attitude of the body is likewise favorable toward gravitational postural drainage. Possibly the one important exception, as previously mentioned, would be the necessary use of the arm lift–chest pressure method (supine position) in cases of advanced pregnancy.

Airway.—One of the major problems, from a practical standpoint, has always been to obtain and maintain an unobstructed and efficient airway in all manual methods of artificial respiration and in all age groups. All texts and manuals emphasize the importance of obtaining an adequate airway before any resuscitative effort is started, and the usual instruction reads, "Quickly sweep your fingers through his mouth to clear out froth and debris and bring his tongue forward." Should it be assumed that this froth, or more frequently, thick mucus, in cases of asphyxia from submersion in salt water, will dry up spontaneously, or that a shapeless mushy tongue will remain in a forward position? If this were the case it would be superfluous to add to the instructions, "Stick a pin or nail through the tongue to keep it in a forward position and occasionally remove any froth or mucus that has formed." In most cases, a pin or nail is about as available as a modern resuscitator. The important fact is that the instructions continue as: "Begin artificial respiration and continue it rhythmically and uninterruptedly until spontaneous breathing starts or the victim is pronounced dead." Experienced operators in the practical application of any form of manual artificial respiration will freely admit that this is frequently one of the most serious complications with which they are confronted, and the condition becomes increasingly worse as the state of apnea is prolonged. I am referring to victims who actually require artificial respiration under circumstances far removed from experimental control. I, as well as many others, have found it absolutely necessary not only to break rhythm but to actually interrupt the artificial respiratory effort on numerous occasions in order to maintain a clear and unobstructed airway. It would be useless to continue under compromising circumstances, regardless of a gross breach in technique. There have been many occasions when inexperienced personnel have continued manual artificial respiratory efforts in the presence of a partial or occasionally a completely obstructed airway unaware of its presence, through lack of knowledge of the symptoms. The results can hardly be expected to be favorable.

Also, in those cases in which an approved mechanical resuscitator is immediately available, with an artificial airway and adequate aspiration, it frequently becomes necessary to repeatedly remove the mask and aspirate. The excellent report by Gordon and co-workers [4] states in part "In the strict sense of the word, manual artificial respiration refers to methods that can be executed by a single operator without the assistance of additional personnel, material, or equipment." [6] At the same time it should be noted that in another report Gordon, Fainer, and Ivy stated, "For the unequivocal comparison of the amount of pulmonary ventilation produced by the different methods, we kept the airway open by introducing and using a McGill endotracheal tube with an inflatable cuff. This yielded an air-tight fit, reliable results and an ideal airway." [7] While it is recognized that, since the major part of their study was concerned with the actual amount of pulmonary ventilation obtained by the various manual methods, the excellent comparative results would not appear to effect this major objective, since this ideal airway was used in all methods studied. Nevertheless one questions whether this, in the strict sense of the word and according to definition, was manual artificial respiration? There is no question about the procedure being indicated and necessary, not only to obtain the results but also, probably more significantly, to act as a safety factor for the volunteer subjects, in view of the means used to render them totally apneic. Certainly the intravenous administration of thiopental sodium and curare in itself presents certain possible inherent airway risks that must be guarded against by the introduction of an artificial or mechanical airway. Gordon and coworkers also mention that the tidal volumes with the push-pull methods may appear to be excessive.[8] A close examination of the spirometer tracings shown in their article, in respect to excursions above and below the base line, demonstrates quite clearly the presence of an excellent airway, since no evidence of even partial obstruction is revealed. It would, therefore, seem that what appeared to be excessive tidal volumes with the push-pull methods under study were, in no small part, the result of the use of the mechanical airway. In this respect the results obtained, in all probability, would not be equaled or even approximated in the practical application of these manual methods in actual cases of accidental asphyxia, especially when the etiological factor is one of submersion. The practical inference that I wish to draw from the preceding discussion is that, since an adequate and efficient airway is one of the first, as well as one of the most important, components of any method of artificial respiration, it must be recognized that what was an ideal and most efficient airway under controlled studies is seldom, if ever, met in actual cases of manual resuscitation. If the resuscitative effort is to be effective, however, an adequate airway in the manual methods must be obtained and maintained without artificial or mechanical means.

In infants and small children this problem from a practical point of view is more complicated than in adults. I believe that adults, in general, at some time or other during their life have been impressed with the fact that infants and small children are, under normal circumstances, generally wet. I refer to the cephalad end rather than the caudal, in keeping with the subject matter of this paper. Anyone who has been dribbled, bubbled, or drooled on is well aware of the fact that this age group either experiences a seemingly continuous form of oral hypersecretion, is unable to cope with normal secretions, or more probably suffers from a combination of both. Many explanations have been advanced for this condition, such as excessive salivary secretions, small buccal area, teething, or hypertrophied lymphoid tissue of Waldeyer's tonsillar ring. It would appear that this age group does not seem to possess the ability to inattentively cope with normal secretions in respect to the act of swallowing. Possibly the child needs something in its mouth to initiate this act, since when it is feeding from bottle or breast it does not appear to exhibit the difficulty to any great degree. I have observed a similar situation in adults, while attempting to relieve a simple ear block in naval aviators. The patient has been asked to close the nares by pinching the nose, close the mouth, and swallow. I have watched many of these patients make all sorts of frustrated attempts to complete the act of swallowing without success. Conversely, have them take a mouthful of water, hold it in the mouth, and repeat the preliminary procedure, and they perform the act of swallowing immediately with no effort. Whatever the explanation, the fact remains that infants and small children are unable to cope with oral secretions under normal circumstances, and this fact becomes a major complication when compounded with hypersecretions in cases of asphyxia, especially one of submersion. An adequate airway must not only be initially obtained but also be maintained throughout the resuscitative procedure. These patients should never be raised in the upright position after a resuscitative response, even though the gag and swallowing reflexes have returned. They should be kept in a slightly head-down position to permit postural drainage until complete recovery.

Pressures.—From what has already been said concerning the use of external pressures in the different methods of manual artificial respiration, especially concerning the difficulty of control with inherent risk of accidental injury, or overcautiousness with resulting inefficiency, it should be obvious that, if external pressures could be eliminated, the method would be much safer in this age group. Internal pressures utilizing the Eve rocking principle [9] are self-controlled, adequately efficient, and not dangerous. It should be noted that the Eve principle is referred to and not the Eve method,[10] which is strictly a mechanical one.

It should also be noted that dangerous pressures in this age group are not confined to those of the expiratory phase. The inspiratory effort, or arm lift phase of the Holger Nielsen method [11] could be just as dangerous, even in experienced hands. It is a well-known fact that the head of the humerus may be acidentally dislocated with very little unintentional pressure when an infant or small child is in a conscious state. Such an accidental dislocation is due mainly to the fact that infants and small children do not possess the inherent safety factor afforded a shoulder by well-developed muscles. In fact, in this age group there is little, if any, muscular development present. Such muscular development does not take place to any marked degree until a later date when, through general body activity and play, these muscles become strengthened and provide more stability to the shoulder girdle. When these facts are considered in a small child in a conscious state, it is not too difficult to imagine what the situation must be when such an individual is in a completely flaccid or unconscious state as a result of asphyxia. The so-called firm resistance that is met in adults in a similar state of flaccidity is barely perceptible, if present, prior to the point of accidental dislocation. Consequently, the margin of safety between adequate and efficient pulmonary ventilation and accidental dislocation bcomes a very narrow one. One could hardly recommend such a procedure as safe and efficient to a comparatively inexperienced general public.

NEED FOR ACCEPTED MANUAL METHOD

From the discussion in the preceding paragraphs and other complications that have been alluded to but not discussed in detail, it would appear that at present no safe, efficient, or completely acceptable manual method of artificial respiration for infants and small children is available for general recommendation to the public at large. If there is, it certainly has not been well publicized and is not known to experienced operators, and I have been unable to locate any publications in regard to its existence.

That a critical need for such a method exists is in evidence almost daily in our newspapers: "Baby drowns in bath while mother answers door bell," "Small child electrocuted while exploring open electric plug connection with hairpin," "Infant smothers in crib," "Child strangles in crib," "Baby boy drowns in unguarded private pool,"—all cases of asphyxia that appear day after day, not usually in big headlines but in small deadly ones. Such incidents as these add up to shocking totals. They are disasters that pass almost unnoticed by the general public; however, they strike deeply the parents and neighbors, especially those who realize that in many of these cases the means of survival could have rested within the framework of their own individual hands. Once more, let me repeat that this is no time to seek aid but rather the time to give it.

Personal interviews with members of rescue squads, police, fire officials, and beach patrol directors in representative large and small municipalities in the United States and Canada have served to emphasize such a need. Many of these groups freely admit that too much reliance is being placed on their immediate arrival at the scene and that little or nothing constructive has been accomplished toward a resuscitative effort by individuals on the scene, pending their arrival. Many of these groups are not very optimistic concerning this lost time that cannot be regained in most instances and is certainly not conducive to recovery. Once more, the longer the state of apnea exists prior to the start of some resuscitative effort, the worse the prognosis. Conversely, we might add that the shorter the time from established apnea to some resuscitative effort, even minimal in effectiveness, the better the prognosis. Another important factor disclosed during these interviews was an attempt on the part of individual members of different groups, in lieu of any recognized standard manual method that was felt safe and effective in this age group, to modify or improvise methods in which the underlying physiological principles had been established. Many of these methods were witnessed in demonstration, but only three (fig. 1 and 2) could be considered provisionally efficient or moderately safe. In figure 1*A*, not only is the position bad, as the infant could very well drown in its own fluids, but it is very doubtful if the volume of pulmonary ventilation would be adequate in cases of even moderately prolonged apnea. Figure 1*B* represents a closer approach to safety and efficiency, since it utilizes the principle of the rocking method of Eve. The main objection would be the inability to obtain and maintain an adequate airway (both hands are occupied) and the inability to provide an effective volume of pulmonary ventilation, since the degree of the arc through which the infant may be rocked with any manner of safety (both hands occupied) is strictly limited. It is by far superior to figure 1*A* and for want of a better method could possibly be used with effectiveness in cases of apnea of very short duration. The ultimate prognosis would at best be guarded.

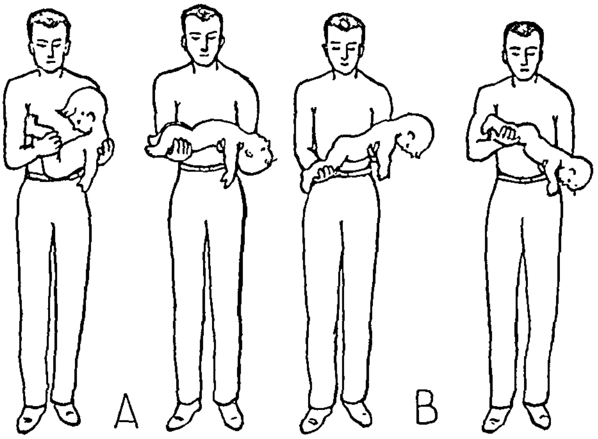

Fig. 1 —*A*, jacknife maneuver with baby on back. *B*, rocking method with baby in prone position.

Figure 2 represents the best modification with one hand grasping the feet. A safety factor is introduced that permits a greater rocking arc with increased ventilation; however, no airway is provided and the head receives no direct support. Consequently, in the head-up position (inspiratory), the head has a tendency to tilt forward producing a partial block in the airway.

PROPOSED CRITERIA FOR NEW METHOD

What criteria of efficacy must an acceptable new method of manual artificial respiration meet in order for it to be recommended and approved by medical authorities and ultimately presented to the general public for practical application? The following criteria are proposed in the order of relative importance to the practical application of such a method based on my rather extensive experience with actual cases of asphyxia due to many causes. Most of these cases were due to submersion and complications resulting therefrom. These probably represent some of the most difficult cases of asphyxia with which an operator is confronted. This situation, as has already been explained, appears more compounded in infants and small children than in adults. Consequently, such a proposal must provide for the best practical components of manual resuscitation possible. 1. The speed with which the method may be applied to the victim following such a catastrophe is of paramount importance. Immediately is the one word that seems to satisfy the first component. 2. The prone position is by far the most desirable one in the majority of cases of asphyxiation. 3. An unobstructed, adequate, and continuous airway is mandatory in all methods of artificial respiration if the method is to be effective. An adequate airway throughout the resuscitative effort must be obtained and maintained. 4. The method must be rhythmic and uninterrupted until spontaneous breathing starts or the victim is pronounced dead. 5. An adequate, preferably a maximal, volume of pulmonary ventilation must be produced. 6. The possibility of injury by the use of uncontrolled external pressures must be eliminated, preferably utilizing internal pressure such as those involved in the Eve principle. 7. The push-pull principle, which also produces essentially artificial circulation, or at least favors venous return to the heart, resulting in an adequate mean arterial oxygen saturation, should be used. 8. The procedure should be executed by a single operator without the assistance of additional personnel, material, or equipment. 9. The procedure should be easy to teach and simple to learn, and it should be one that may be performed accurately, efficiently, and safely by anyone. 10. It must not be unduly tiring to the operator over a reasonable period of time (probably 10 to 15 minutes) and should provide modifications resulting in change of position to lessen the chance of operational or positional fatigue to the operator.

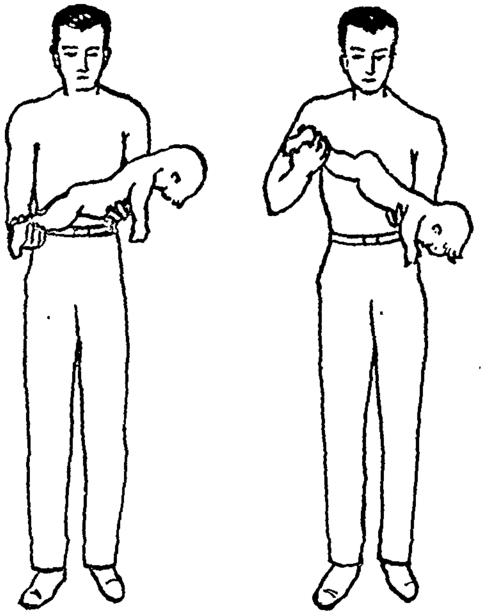

Fig. 2.—Rocking method with baby held by feet.

A manual method of artificial respiration that would provide for these components as listed would seem to be one that could be proposed as safe and efficient. Such a method, no doubt, could be termed new, even in view of the fact that several well-established and proved principles will be incorporated into the technique. Whether or not it will be approved and accepted by medical authorities, professional groups, and the general public for practical application should depend mainly upon how well it provides for the critical components of manual artificial respiration for this age group listed above.

The birth and proposal of any new method of manual artificial respiration demands a name, preferably one that not only is descriptive of the basic position and maneuvers but indicates and is a constant reminder to all operators that one of the practical fundamental acts in initiating any method of artificial respiration is to begin with the expiratory phase. The logic of this action is quite clear when one considers the possibility and probability of obstructive material lying in the region of the tracheal opening ready to be aspirated with the first inspiratory effort, if not preceded by one of expiration to clear the area. In many texts and publications on manual artificial respiration the descriptive terms of different methods are referred to as arm lift–back pressure, hip lift–back pressure (Schafer–Emerson–Ivy), and arm lift–chest pressure.

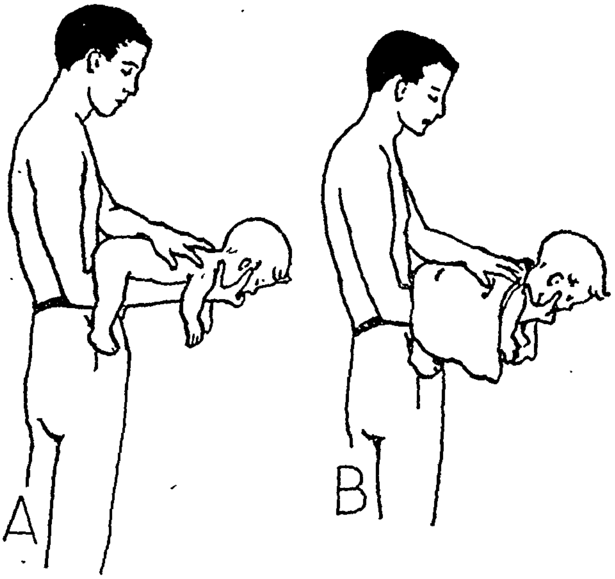

Fig. 3.—*A*, modified Mauriceau position, lateral view. *B*, same position with cover.

I seriously object to this inconsistency in position of descriptive terms for two reasons. First, it is not only incompatible with the best resuscitative procedures but also not consistent with descriptive techniques. The procedure should always begin with the expiratory phase and the descriptive term should so imply as, back pressure–arm lift or back pressure–hip lift. Secondly, it results in confusion in teaching since the lay person will invariably and instinctively practice in the order in which he repeats to himself and learns. It may be recalled that this teaching method was used to excellent advantage by instructors for the American National Red Cross in teaching the prone pressure method. The student was taught to repeat to himself "Out goes the bad air, in comes the good; out goes the bad air, in comes the good." While this procedure was primarily instituted in order to give him a sense of rhythm and timing, it likewise served to remind him that it was important to begin with the expiratory phase in order to avoid possible aspiration.

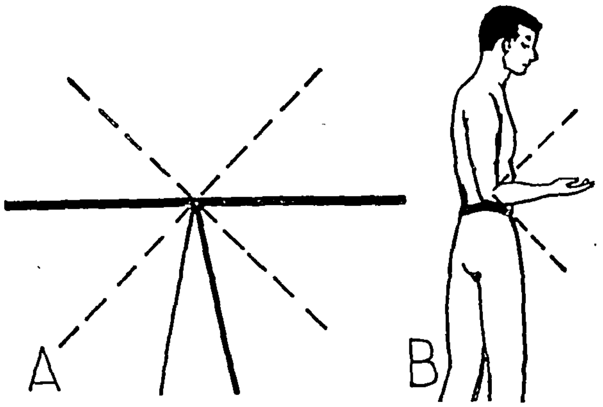

Fig. 4.—*A*, diagram of Eve method. *B*, Eve principle.

A review of the different manual methods of artificial respiration reveals that in the past it apparently was customary for the individual who devised and offered a new method or modification to associate his last name with the method followed by a suitable descriptive name. For example, we have the Silvester (arm lift–chest pressure); Schafer (prone pressure); Eve (rocking); Holger Nielsen (arm lift–back pressure) Schafer–Nielsen–Drinker (modification of Nielsen method); Emerson (hip lift); and Schafer–Emerson–Ivy (prone hip-chest method). It is presumed that this custom was initiated and continued for purposes of identification of each method or modification and to prevent confusion in the teaching of the different techniques. Whatever the reason, I will conform with the established precedent and continue the custom of the past.

Rickard Prone Tilting–Visceral Shift Method

There are two principles used in this new method, called the Rickard prone tilting–visceral shift method: first, the position of the subject during the Mauriceau breech extraction maneuver,[12] with appropriate modification to obtain and maintain a continuous digital airway and provide for extension of the lower jaw and lateral support to the head in order to maintain it in a midline position (fig. 3*A*). In this position, the subject may also be covered to preserve body temperature (fig. 3*B*). Second is the principle of the Eve method [10] (without the usual apparatus or device), used to eliminate the application of potentially dangerous external pressures (fig. 4). The descriptive title of this method indicates the position of the subject, the active expiratory and inspiratory phases, and the fact that safe pressures are supplied entirely by the shifting of the abdominal viscera.

POSITIONING OF SUBJECT

If the subject is found lying in the supine position (fig. 5*A*), the middle finger of the right hand, bent at the second joint to form a 90 degree angle, should be placed in the subject's mouth, over the tongue, in order to draw the tongue slightly forward and depress it into the floor of the mouth. The thumb and index finger and the ring and little finger are placed on either side of the lower jaw so as to extend it in a forward position and add lateral support and stability to the head, which is maintained in a midline position (fig. 6). The midline position of the head also aids in obtaining and maintaining a more direct and unhampered airway, in contrast to the usual positioning in other methods, where the head is turned to one side or the other, resulting in a torsion or twisting of approximately 90 degrees. Roll the subject over in a face-down (prone) position onto the right forearm with the arms and legs of the subject in a straddling and pendant position (fig. 3*A*). If the subject is found lying in a prone position, grasp his right thigh with the left hand, raising the body sufficiently to position the right hand and forearm as previously described and permit the subject to be lowered onto the right forearm in a prone and straddling position (fig. 5*B*).

The left hand is now placed (palm down) across the back with fingers spread on either side of the neck and hooking across the shoulders (fig. 3*A*). Such a positioning of the left hand not only adds to the security of the subject on the forearm but permits a greater angle of arc through which the subject may be tilted, with safety, in executing the basic maneuvers. It should be noted that the middle finger, not the index finger, is placed in the mouth (fig. 6). (Mauriceau's maneuver utilizes the index finger.) These positions of the operator's hands and fingers, as well as the position of the subject, are maintained throughout the entire resuscitative procedure.

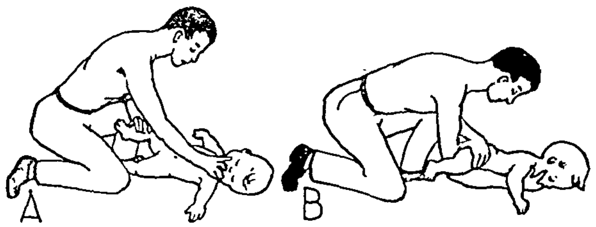

Fig. 5.—*A*, positioning from supine position. *B*, positioning from prone position.

POSITION OF OPERATOR

The operator should rise to a standing position with the subject draped across the forearm as described, keeping the forearm at right angles to the upper arm and parallel to the ground or floor (fig. 2*A*). The upper arm must be kept in close contact with the lateral chest wall, slightly anterior, in order to shift most of the subject's weight to the operator's shoulder girdle, thereby relieving the muscles of the upper arm from most of the so-called dead weight (fig. 7). It should be emphasized that these positioning maneuvers, both of the subject and the operator, while requiring considerable time to explain, actually are accomplished in a matter of seconds.

---

[12] Stander, H.: Text Book of Obstetrics: Designed for the Use of Students and Practitioners, 3rd revision, New York, D. Appleton-Century Company, Inc., 1945, pp. 1062-1063.

EXPIRATORY PHASE

Begin immediately and always with the expiratory phase (fig. 8*A*). Time is of prime importance. Do not delay for any secondary reasons such as moving the subject, loosening clothing, warming, or applying stimulants. Lower the forearm (extension) to a position of approximately 45 degrees, which will place the subject in a head-down attitude. The abdominal viscera will shift and push against the diaphragm in this position, forcing air out of the lungs. At the same time, expulsion and drainage of fluids and debris is accomplished not only by gravity but by the previously established and maintained airway.

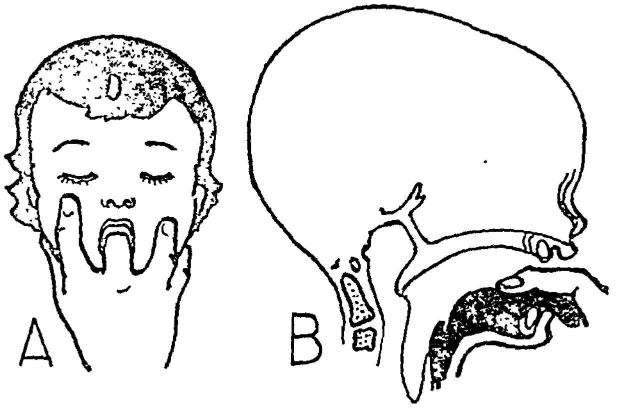

Fig. 6.—*A*, position showing showing digital airway. *B*, lateral view.

INSPIRATORY PHASE

At the completion of the expiratory maneuver, the subject will be raised to the inspiratory phase (fig. 8*B*), a head-up position of approximately 45 degrees, by lifting the forearm (contraction). The abdominal viscera will shift in the opposite direction from the previous one, releasing the pressure and causing an actual pull or tug on the diaphragm, due to the visceral ligamentous attachment. This maneuver will result in air being sucked into the lungs, completing the inspiratory phase and respiratory cycle.

RATE AND RHYTHM OF CYCLES

The rate of the tilting cycle should be between 8 and 12 times per minute through an arc of 45 degrees, head-down position, to that of 45 degrees, head-up position, in rhythmic and uninterrupted sequence, until spontaneous breathing starts or the victim is pronounced dead. It is highly recommended that the operator, in order to accomplish a reasonably accurate sense of timing and rhythm, repeat to himself the following phrases: "Out goes the bad air (expiratory phase), in comes the good air (inspiratory phase)" for a complete cycle rate of 12 times per minute; "Out goes the bad air and (expiratory phase) in comes the good air (inspiratory phase)" for a complete cycle rate of 8 times per minute. It should be noted that each expiratory phase (always the first maneuver) begins with the word "out" and that each inspiratory phase begins with the word "in." If this suggestion is followed and the count not hurried, it will be found that the first example requires 5 seconds per cycle and results in a rate of 12 cycles or respirations per minute. The second example, by insertion of the word "and" in the expiratory phase, requires approximately seven and one-half seconds per cycle and results in a rate of eight cycles or respirations per minute.

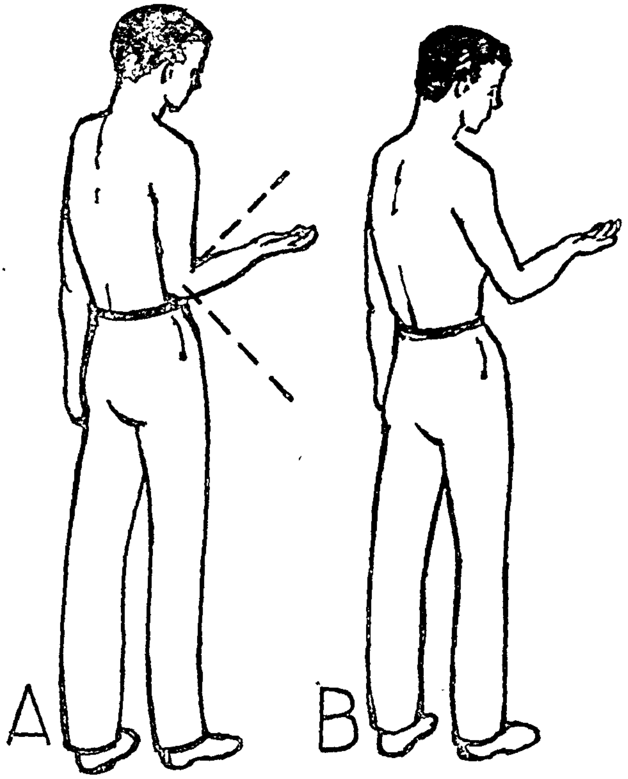

Fig. 7.—*A*, correct arm position with arm close to body. *B*, incorrect arm position with arm away from body.

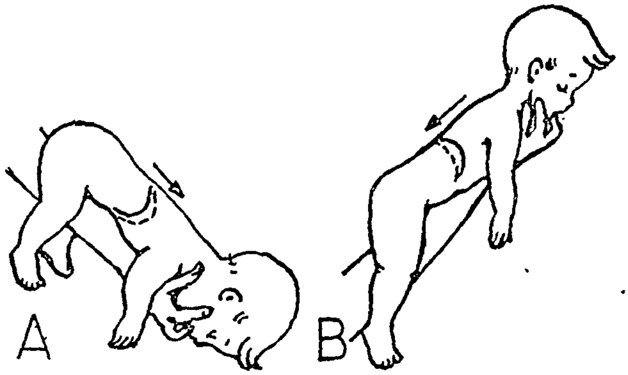

Fig. 8.—*A*, expiration-head-down position showing visceral shift against diaphragm. *B*, inspiration-head-up position showing visceral tug on diaphragm.

It should be realized that timing and degrees of arc are more relative than actual in the practical application of artificial respiration; however, a reasonable attempt to simulate normal respiration must be made. The average inexperienced operator has a great tendency to hurry these maneuvers unless some simple repeat-phase is used to give him a sense of rhythm and timing. In cases of asphyxia by submersion and other cases that are frequently complicated by excessive amounts of fluids, it would be advisable to use the eight times per minute cycle and limit the head-up position to a 30 degree arc until the victim has become essentially dry. At that time the rate should be increased to 12 times per minute and the head-up position to the full 45 degree arc. This precaution not only provides a slightly prolonged expiratory phase, during which more complete drainage of fluids takes place, but also lessens the chance of accidental aspiration. In fact, it has been reported, in studying these components, that a rate of 8 times per minute increased the volume of each cycle but not the minute volume as compared to 12 times per minute.[18]

MODIFICATIONS OF POSITIONS OF OPERATOR

After positioning the subject as previously described, the operator may, instead of rising to a standing position, kneel on the left knee, placing the right leg in a right-angle position with the thigh parallel to the ground. The operator's right elbow is then placed upon the right thigh sufficiently close to the knee to permit free action (45 degrees) in the downward tilt, and resuscitation is started immediately (fig. 9). Many asphyxial emergencies occur in places such as the home, private swimming pools, and other places where chairs, benches, tables, and other household and patio furnishings are immediately available. Under these circumstances of immediate availability of a suitable place to sit, the operator may even further conserve his energy by assuming positions as illustrated in figure 10 or 11. It should be noted in these diagrams (fig. 9, 10, and 11) that the two essential factors necessary for these modifications are: (*a*) the object be of sufficient height to enable the operator to function properly and (*b*) the thigh be kept at a close parallel with the ground and sufficiently above it to obtain the necessary 45 degree angle head-down tilt.

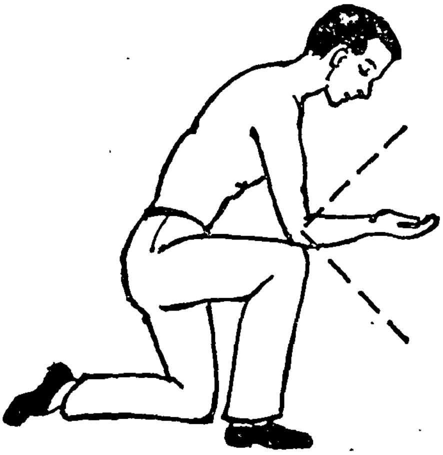

Fig. 9.—Modification to kneeling position.

All of these modifications may be used where possible to the operator's advantage and with no change in the basic resuscitative technique. The kneeling modification (fig. 9) is especially recommended as an alternate position with that of the standing position (fig. 3*A*), and the change may be accomplished without break in rate or rhythm. Resuscitation may be continued almost indefinitely by effecting this change, especially in the heavier children in this age group. The weight of the subject, as may be seen from the diagrams, is placed almost entirely upon the thigh and indirectly on the ground. The change in the operator's position also serves to eliminate any postural or positional fatigue at the shoulder that may occur with a heavy subject and an unusually prolonged resuscitative effort.

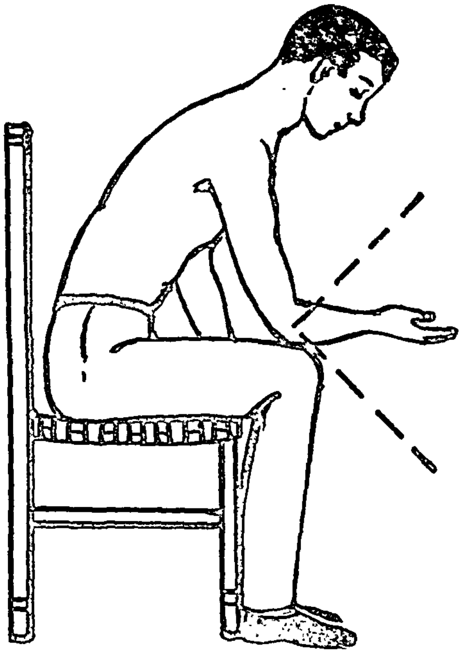

Fig. 10.—Modification to sitting position.

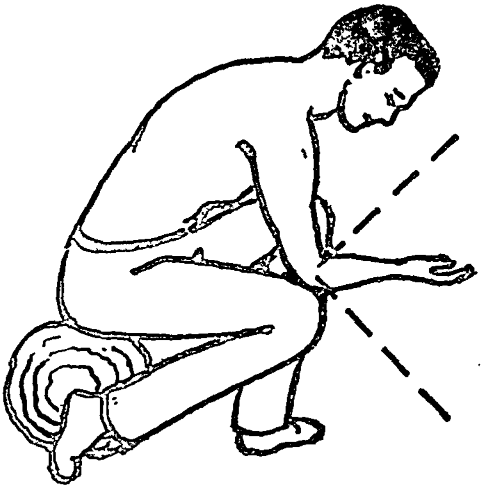

Fig. 11.—Modification to bent knee on low seat.

13. Gordon, A. S.; Fainer, D. C., and Ivy, A. C.: Artificial Respiration: A Comparative Study of Different Methods in Adults Including a New Method, in Special Report, Conference on Artificial Respiration, held at Medical Division, Army Chemical Center, Maryland, on 29-30 September 1950, (April) 1951, p. 73.

PRACTICAL USE OF DIGITAL AIRWAY

A rather important point in relation to the practical use of the digital airway should be explained. No provision has ever been made for such an airway in any method of manual artificial respiration in the past. Consequently, some misunderstandings or questions may be raised in the minds of those who have had limited experience with the practical application of resuscitation concerning predisposition to regurgitation and aspiration of stomach contents. It must be readily admitted that the possibility of accidental aspiration is present in all methods of artificial respiration, both manual and mechanical. The area in the immediate vicinity of the tracheal opening is never completely free of mucus and secretions in normal life. As a result we experience aspiration of small particles of food and fluid in a conscious state of being.

Certainly, then, this situation and possibility is not only present but actually compounded in a state of unconsciousness, where the swallowing reflex is completely abolished and hypersecretions and fluids are present. This condition is particularly true in cases of asphyxia by submersion. The introduction of a digital airway that is maintained throughout the entire resuscitative procedure would appear to greatly lessen the chances of such a condition occurring. In addition it will be recalled that the subject's head is maintained in a midline position with the lower jaw extended, thus providing a direct exit during the expiratory phase. Fluids are not retained in the buccal areas to be aspirated with each succeeding inspiratory phase, and the victim actually has a tendency to dry up more rapidly than in presently accepted methods. With these methods, which utilize the prone position with the head turned to one side or the other and the cheek resting on the hand, there is actually more chance of accidental aspiration, since the buccal area is not completely cleared of fluids and each succeeding expiratory pressure raises a little more fluid from the stomach. This fluid cannot be completely expelled from the mouth, even in a slightly head-down position of the victim, since the position of the head results in a torsion of the neck, an unextended lower jaw, and trapping of fluids. I feel that this situation will be improved by the introduction and provision of an adequate airway with maximal chance of a rapid clearance of fluids and with actually less chance of accidental aspiration.

PEDAGOGIC AND PERFORMANCE FACTORS

Assessment of the degree of difficulty in teaching, the accuracy of performance, and the degree of discomfort and exertion by prospective operators, in a practical sense, is essential. This presented quite a problem in the evaluation of this new method of artificial respiration. I felt that, since the method, as proposed, advocated the use of several components that were new or had new application, in comparison to those currently in use on adults, it was only proper that it be presented to medical groups first. Consequently, a large group of nonmedical personnel was purposely avoided in obtaining the assessment data of the pedagogic and performance factors in order to prevent predisclosure, with possible adverse results. In addition, it was realized that this information could not be obtained from actual practice on live and conscious subjects, even if available. The presence of the swallowing and gag reflexes would prohibit the application of the airway component, and it was felt that the position advantage (prone) of the Mauriceau maneuver as well as the advantage of the Eve principle utilizing internal pressures were too well known to require extensive evaluation.

A random selection of operators, with no previous instruction in this method, was made and the method explained and demonstrated, with the use of partially filled sandbags of varying weights including those of 7, 14, 21, and 30 lb. (3.2, 6.4, 9.5, and 13.6 kg.). Manikins were used to demonstrate the application and positioning of the middle finger to maintain the digital airway and the use of the remaining fingers to extend the lower jaw and add support to the head in a midline position. A stop watch was used to time the speed of application and to devise suitable repeat phrases in order to develop uninterrupted rhythm timing of 8 and 12 cycles per minute. The pedagogic information obtained was that after one period of instruction, all personnel, without exception, were able to repeatedly place the method in operation within an average period of six seconds, and no difficulty was experienced with any component or its execution. The general conclusion was that it was easy to learn.

Next, the performance factor was assessed by using sandbags representing the approximate weights and relative sizes of infants and small children ranging from one week of age (8 lb. [3,628.7 gm.], 21 in. [53 cm.]) to 2 years of age (30 lb. [13.6 kg.], 34 in. [91 cm.]). Note that the relative sizes as given represent the measurements from head to foot and, since the legs are straddled across the forearm, no difficulty was experienced in these representative groups. The length of the forearm of the average individual will easily accommodate this age group without any interference to the required range of angle at the operator's elbow joint. The operators performed the technique in a rhythmic and uninterrupted manner for a period lasting 10 minutes. The 10-minute period was felt to represent a reasonable one for manual artificial respiration; however, many of the operators continued for periods as long as 15 and 20 minutes with the lighter weights (8 to 16 lb.) and did not feel unduly tired. Under emergency conditions it was felt that these longer periods could be duplicated and even extended if necessary. There was one factor that was noticed by all operators. This condition was noticed in the use of the heavier bags (24 to 30 lb.) and was not one due to activity of the forearm but rather inactivity of the shoulder. It could be termed a positional or stability fatigue. Since most of the victim's weight is transmitted to the operator's shoulder girdle indirectly, it was noted that, as the 10-minute period approached the last few minutes, the operators, while holding the upper arm close to the body, attempted to move it slightly anterior to the lateral chest wall in order to gain support to the shoulder by anchoring the elbow. The condition was described, not as a tiring one, but as an uncomfortable or crampy feeling in the shoulder muscles relieved by a slight position change that gave support to the elbow. With this evidence and experience in mind, I devised several modifications to the basic position of the operator that not only eliminated this situation and were quite applicable to the heavier children but could be used routinely by female or young operators of slight physical stature. They have been described and illustrated previously.

The results of the assessments were expressed in a unanimous opinion by the operators that the method was easy to learn and not tiring at all with the lighter weights and only moderately so with the heavier weights. They could continue under emergency conditions by simply shifting the position of the upper arm. The shifting does not interfere with the accuracy of the performance nor with the efficiency of the method; however, it can be avoided completely by using the previously described positional modifications.

COMMENT

The critical need for a practical, safe, and efficient method of manual artificial respiration in infants and small children has been substantiated by personal observations and interviews among groups of professional operators who perform 90 to 95% of the rescue work in the United States and Canada and probably throughout the world. This particular age group represents one in which the opportunity for accidental asphyxial emergencies is greater than in any other age group throughout the span of life. It is, likewise, a group in which the anatomic development and the physiological processes have not had sufficient time to develop any marked safety factor or reserve, as compared to the adult.

Consequently, whatever is to be accomplished in a resuscitative way must be prompt, safe, and efficient. These criteria can only be met by someone on the scene and in possession of a method based on sound medical recommendations. In a final analysis, the determination of the most efficacious method will not come solely from laboratory results. The groups who provide the practical application of all intelligently proposed and approved methods for the rescue of humans must give the final evaluation regarding these methods, as it pertains to human resuscitation.

SUMMARY AND CONCLUSIONS

The descriptive name, Rickard prone tilting–visceral shift, that has been assigned to a new method of manual artificial respiration for infants and small children indicates the position of the victim and that the expiratory phase is the initial one and the shifting viscera produce an active expiratory and inspiratory phase, or a push-pull method. The development was based on two sound and proved principles; namely, utilization of the position in the Mauriceau maneuver, with practical modifications and application of the principle of the Eve rocking method.

The method is strictly manual by definition in that it is executed by a single operator without the assistance of additional personnel, material, or equipment. A continuous digital airway is introduced for the first time in manual artificial respiration, and the head of the victim is placed and supported in the midline, eliminating the torsion that is present in other methods when the head is turned to one side or the other. External pressures that have proved dangerous in the past have been replaced by safe and effective internal pressures that are self-controlled—the push-pull action that has been proved most effective.

The method is simple to teach and easy to learn and does not require any great expenditure of effort or unusual degree of discomfort to the operator in order to perform accurately, safely, and efficiently for what has been determined to be a reasonable period of 10 to 15 minutes. Use of the recommended modifications, although not necessary, will alleviate any tendency to positional fatigue experienced by the operator. As mentioned before, the modifications are practical suggestions that may be utilized if circumstances permit.

The method was devised to be used in an age group ranging from 7 to 8 lb. (3,175.1 to 3,628.7 gm.) to a maximum of 28 lb. (12.7 kg.) in weight, which represents in age a small child from one week of age up to a maximum of 2 years of age. It will be recognized at once that many 2-year-olds have developed sufficiently in size, weight, and muscular support that the Holger Nielsen (arm lift–back pressure) method may be applied with a certain amount of caution.

From a practical point of view, it is felt that application of this method fulfills the criteria that have been proposed for an efficient, safe, and acceptable method of manual artificial respiration in infants and small children. It has been repeatedly emphasized and authenticated that proposed and enacted legislation to enforce safety factors will not ever result in absolute prevention. While it is a step in the right direction, it too frequently results in a false sense of security. The fact remains, as stated and recorded by those who respond to the majority of asphyxial emergencies, that these cases are on the increase. Most important of all is the well-established, practical assertion by these groups of professional operators that the element of time from the discovery of a case of apnea until an operator arrives on the scene is of paramount and critical importance to the success or failure of resuscitation.

This situation appears to be particularly true in children of the helpless and exploratory ages. The present lapse in activity must be replaced by active and intelligent resuscitative effort of an approved and effective nature if results are to be improved in the future. Certainly, if recovery is a possibility, immediate and effective resuscitation is the one and only single factor that will result in its accomplishment. Failure in this respect can be attributed only to lack of interest by society, since all members, with few exceptions, possess the fundamental requisites to accomplish this end and have them available for immediate use at all times—the hands.

FIFTY YEARS OF ORGANIZED ANESTHESIOLOGY

Albert M. Betcher, M.D., Benjamin J. Ciliberti, M.D., Paul M. Wood, M.D.
and
Lewis H. Wright, M.D., New York

The oldest society organized for physicians interested in anesthesiology in this country traces back to a group founded by Dr. A. F. Erdmann. He invited these physicians to a meeting at the Long Island College Hospital in Brooklyn, N. Y., on Oct. 6, 1905. Eight physicians responded that evening to his invitation to get together and form an anesthesiology society. Although there probably were other groups who had met before this date, this society, named the Long Island Society of Anesthetists, has been meeting formally and continuously, changing only its name, to the present day (fig. 1). On that memorable evening, plans were made for regular business and scientific sessions, and dues were set at one dollar per year. The records of this infant society are unfortunately incomplete for the next few years due to a fire in 1911 at the home of the secretary, in which all records were burned except for the original notebook in which the constitution was written. But, during these years, the society met regularly and conducted its scientific sessions on new anesthetic equipment and methods of administration of the agents then employed.

Fig. 1.—Historical development of American Society of Anesthesiologists and International Anesthesia Research Society.

In 1911, pressure was put on the Long Island Society of Anesthetists to move over to Manhattan. The founders had set the number of charter members at 50, and at this time they were still short of that figure. It was urged that many anesthetists outside Brooklyn would join because of the great interest in the scientific sessions. Thus, at the May 31 meeting, a committee was appointed to present a plan for a new constitution. In October of the same year, while Erdmann was president, the name was officially changed to the New York Society of Anesthetists. Dr. James T. Gwathmey was elected the first president at the second regular meeting of the New York Society of Anesthetists on Feb. 7, 1912. Dues were increased to $3 per annum, and the purpose of the society was defined as the advancement of the science and art of anesthesiology. The charter membership was now completed. Continued interest in the possibility of the organization's being national in scope led to more requests by physicians for membership. In fact, there were 103 physicians present at the May 12, 1912, meeting. It was at this meeting that the executive committee was instructed to consult with the American Medical Association about forming a section on anesthesiology within the latter organization.

In the meantime, other organizations in the field of anesthesiology were appearing in this country. Although an organization called the American Association of Anesthetists had had a first formal meeting during the American Medical Association convention in Minneapolis in June 18, 1913, its activities did not become important until one of the foremost pioneers in American anesthesiology, Francis McMechan, took over the reins. In addition, in 1915, he organized the Interstate Association of Anesthetists of Ohio and Kentucky. By 1916, as organization secretary of the American Association of Anesthetists, he directed the society's policy. McMechan enlarged it so that, by 1926, it was changed to the Associated Anesthetists of the United States and Canada. At the same time, the Interstate Association was changed to the Midwestern Association of Anesthetists. McMechan also helped to found the Canadian Society of Anesthetists, which later became the section on anesthesiology of the Canadian Medical Association. He also aided in the formation of the Pacific Coast Association of Anesthetists, the Eastern Society of Anesthetists, and the Southern Association of Anesthetists. All these sectional societies later became regional societies of the Associated Anesthetists of the United States and Canada.

Still the organizational enthusiast, McMechan, in 1919, founded the National Anesthesia Research Society in Cleveland. This society was promoted by E. I. McKesson, a manufacturer of anesthesia appliances, and was meant to include manufacturers of anesthetic drugs and apparatus, who, as nonphysicians, were ineligible for membership in the above organizations. In fact, there were laymen on the governing board of the National Anesthesia Research Society. In 1925, it became exclusively professional. In this year, the name was changed to the International Anesthesia Research Society to include anesthetists from all over the world. As a result of visits McMechan made to other countries, the board of governors inaugurated the International College of Anesthetists. They planned to certify specialists in anesthesia by 1936. The American Society of Regional Anesthesia was started by a group of anesthetists and neurosurgeons in 1923. Its original intent was to honor Gaston Labat, who had developed the art

---

Read before the Section on Anesthesiology at the 104th Annual Meeting of the American Medical Association, Atlantic City, June 8, 1955.

of local infiltration and nerve block techniques. Although it was a small organization, its existence later proved of inestimable value.

Meanwhile, the New York Society of Anesthetists regularly conducted its programs of business and scientific sessions. Prominent speakers, including nonanesthetists contributed to those sessions. Candidates for membership appeared from the neighboring states of New Jersey, Pennsylvania, Connecticut, Massachusetts, and Maryland. By 1915, there were 70 members. An "associate membership" for dentists who showed special qualifications in anesthesiology also helped to increase the membership. The year 1917 saw members of the New York Society of Anesthetists offering their services as individuals to serve in the armed forces as specialists in anesthesiology. Drs. Booth, Buchanan, Guedel, Gwathmey, and Munkittrick were among those who served overseas, organized training centers, and contributed to resuscitative measures for patients exposed to poison gas. At the meeting of Nov. 8, 1917, Major George W. Crile, who had just returned from the war front, addressed the membership. At the conclusion of the war, the New York society attempted to gather the fruits of the gains made during the war effort. Efforts were restarted in 1921 to obtain a section on anesthesiology in the American Medical Association; however, letters sent to the Secretary and responsible committees of the American Medical Association met with no success for the next 10 years.

STEPS TOWARD A. M. A. RECOGNITION

In 1933-1934 the Advisory Board for Medical Specialities was set up. This board did agree to meet with an anesthesiology committee, but only representatives from the International Anesthesia Research Society and the Associated Anesthetists of the United States and Canada were invited. Although there was representation in the New York Society of Anesthetists of physicians from throughout the country, its "local" name precluded an invitation. However, since only organizations that had sections in the American Medical Association could be considered, this invitation was meaningless. The New York Society of Anesthetists then directed its efforts to raise its own standards by granting certification by the society. Late in 1934, they empowered their committee on certification to print application blanks for the granting of fellowships in anesthesiology. Their plan was to hold a written, oral, and practical examination in accordance with the principles of the Advisory Board for Medical Specialties. This plan eventually would be submitted for approval to the advisory board.

Meanwhile, candidates from states beyond the eastern Atlantic seaboard area were applying for membership in the New York society. These included anesthetists from Ohio, Texas, Georgia, Minnesota, Oklahoma, and Nevada. These efforts, literally due to the one-man crusade of the secretary-treasurer, Paul M. Wood, renewed hope of recognition by the American Medical Association of the specialty of anesthesiology. By the time of the Jan. 15, 1936, meeting, several members had received the certificates, designating them as "Fellows in Anesthesiology." Among those recommended for fellowship were Joseph Lumbard and Moses Krakow of New York, Ansel Caine of New Orleans, Charles McCuskey of Los Angeles, Ralph Waters of Madison, Wis., and Sidney Wiggin of Boston. There was further evidence of the national character of the New York society in the recommendation of Paul M. Wood for a revision of the constitution to include a new permanent committee, the public relations committee.

All these events, coming with such rapidity after 1934, stimulated the executive committee of the New York society to such a fervor that they polled their members by mail for their reaction to changing the name of the society. At the following meeting on Feb. 13, 1936, with excitement evident in the hall, the secretary-treasurer explained the reason for the proposed change in name. The motivating purpose was to make this society a national anesthesiology society, in name as well as in fact. Nothing would be changed except to replace the words "New York" with "American" througout the constitution. He reviewed the unwillingness of the American Medical Association and the Advisory Board for Medical Specialties to accept any organization whose title might indicate a local society. It followed, therefore, that, to assume the responsibilities of a national organization, it must have a name that was national in character. Of the 124 replies received to the questionnaire, 120 had been in favor of and 4 had been opposed to the change. One of those opposed had been its founder, A. F. Erdmann, who had feared being swallowed up by a new organization, as occurred in 1911, when the Long Island Society had become the New York Society of Anesthetists. However, as he voiced these fears aloud, he concluded, "I am overwhelmed by the recognition of the changes which will take place and by the fact of the necessity for making these changes."

The first business taken up after changing the name to the American Society of Anesthetists was the appointment of John Lundy to represent the group at a meeting of the American Medical Association and of the Advisory Board for Medical Specialties. However, neither group showed any enthusiasm for prompt approval. Then a possible solution appeared as a result of the group's previous efforts to elevate its status. Ralph Waters, one of the early advocates of uniting the basic medical sciences with clinical anesthesiology, had instituted a five year residency program in anesthesia at the University of Wisconsin. E. R. Schmidt, professor of surgery at the same university, was influenced by the anesthesia program of Waters and was very anxious to see the anesthetist keep pace with the surgeon in professional recognition. At the time the American Society of Anesthetists changed its name, Schmidt was in the East to amalgamate the various surgical societies in order to obtain a board of surgery. He intimated to the anesthesiology society that, if the American Medical Association refused to recognize any additional specialties, he would ask the surgical group to certify anesthetists as an associate board to the American Board of Surgery. As Buchanan reported this meeting to the society membership, "It is a long hard fight, but we eventually, I think, will get our place."

To obtain recognition as a specialty by the American Board of Surgery, it was necessary to have representation of some of the national societies of the specialty. Invitations were extended, therefore, to the International Anesthesia Research Society, the Associated Anesthetists of the United States and Canada, and the American Society of Regional Anesthesia, as well as to the American Society of Anesthetists. The first two societies decided against joining in this plan of certification; however, the small organization called the American Society of Regional Anesthesia, almost extinct because of its lack of dues-paying membership, allied itself with the American Society of Anesthetists. It retained a spark long enough to justify the prepared statement sent to the Advisory Board for Medical Specialties. The statement declared that anesthesiology was a specialty and as such should be recognized and that an American board of anesthesia was being formed and had representatives from the national organizations.

On Dec. 10, 1936, the old society with the new name was officially incorporated as the American Society of Anesthetists, Incorporated. A new constitution and bylaws were adopted, making dentists no longer eligible for membership. The offices of secretary and treasurer were separated. The governing and advisory body was to be a board of directors of 18 members. The constitution likewise provided a committee on fellowship, consisting of nine members. Annual dues for the 487 members were now increased to $5. The members were urged to attend the American Medical Association meeting at Atlantic City, N. J., in June, 1937, to register in the Section on Surgery and to add the word "anesthesia" in parentheses. In October, 1936, three representatives from the Section on Surgery of the American Medical Association met with representatives of the two national anesthesiology societies that had requested a certification board. It was recommended that the anesthetists' representatives to the board be appointed from the Section on Surgery. The first representatives were to be fellows of the American Society of Anesthetists. With this recommendation, the Section on Surgery accepted the responsibility of sponsoring anesthesiology as a related section. Subsequently, at the meeting in Chicago to set up the American Board of Surgery, the Advisory Board of Medical Specialties recommended that the anesthesiology societies apply to the American Board of Surgery to join on the basis of an affiliate board.

The plans for affiliation of the American Board of Anesthesiology with the American Board of Surgery were completed on June 2, 1937. The plan was approved by the American Society of Anesthetists and the American Society of Regional Anesthesia. It conformed in all respects to the examining boards of other medical specialties. The members and associate members of the examining board were selected by a committee representing the above two anesthesia societies and the Section on Surgery of the American Medical Association. In February, 1938, the Advisory Board for Medical Specialties approved the affiliation. Official recognition of physicians competent to practice and teach anesthesiology as a specialty was now an accomplished fact.

Now, in 1939, the American Society of Anesthetists turned its efforts again to establish a section on anesthesiology in the American Medical Association. California, Connecticut, and Indiana had already established sections on anesthesiology in their state medical societies. There was an awareness that the American Medical Association was more friendly to organized medical anesthesiology. A further inquiry led to a proposed meeting with the A. M. A. Council on Scientific Assembly for November, 1939. In advance of this meeting, the group was further heartened by the receipt of a letter from James E. Paullin, Chairman of the Council of Scientific Assembly. It read in part: "Of course, I cannot speak for the entire council, but I do believe that the establishment of a Section of Anesthesiology would be for the good of the American Medical Association and I think it would help your specialty very much—a subject in which I wish to say I am enthusiastically interested."

The Council on Scientific Assembly at the above meeting agreed to recommend to the House of Delegates that a section on anesthesiology be established. In June, 1940, at the Annual Meeting of the American Medical Association, the House of Delegates voted unanimously to establish the Section on Anesthesiology in the American Medical Association. Anesthesiology was now a recognized specialty. In the meantime, rumors were heard that the six affiliate surgical boards of the American Board of Surgery were in favor of separating and becoming separate individual boards. Since anesthesiology had gained its own section, this was now possible. In 1941, the Advisory Board for Medical Specialties approved the American Board of Anesthesiology as a separate major board, with the unanimous consent of all participating societies and boards.

ATTAINMENT OF OTHER GOALS

There was still another objective in the minds of the original founders—the formation of a journal devoted to anesthesia. In 1914, at McMechan's persuasion, the *American Journal of Surgery* established a quarterly supplement of anesthesia and analgesia in that publication. It became the official organ for the existing anesthesiology societies and was continued for about 10 years. McMechan, himself, after founding the National Anesthesia Research Society, provided this organization with a monthly bulletin, which was enlarged in 1922 to the present official organ, *Current Researches in Anesthesia and Analgesia.* This was the first medical journal in the United States devoted entirely to anesthesiology. In 1937, the journal club of the section on anesthesia of the Mayo Clinic started a publication, *Anesthesia Abstracts.* It was under the editorial direction of John Lundy and is still published today.

The New York Society of Anesthetists in 1935 began to mimeograph reports of its business and scientific sessions. Copies were sent to the membership and provided a means of disseminating the latest advances in anesthesiology. In 1938, McCarthy of Toledo, Ohio, chairman of the committee on public relations of the American Society of Anesthetists, started a monthly newsletter. It included reports on anesthesiology from recognized journals. In October of the same year, a committee was appointed to obtain information regarding a journal representing the American Society of Anesthetists. Early in 1940, an editorial board, policy committee, and consulting editors were appointed. The new journal was named *Anesthesiology*. The first issue appeared in July, 1940, and was sent to 568 members and 300 additional subscribers. It has been published bimonthly since and today has a combined circulation of 7,231 copies per issue.

Still another purpose of organized anesthesiology was to expand educational facilities in medical schools and hospitals. In 1935, the committee on education of the New York Society of Anesthetists sent a questionnaire to 87 medical schools in the United States and Canada about the teaching of anesthesiology in their curriculum. Of the 75 schools that replied, 58 listed anesthesiology instruction as a separate subject given by a physician, 5 listed anesthesiology instruction given by nurses, 5 listed anesthesiology instruction as part of surgery or pharmacology, and 7 gave no instruction in anesthesiology at all. The society then published a resolution that the departments of anesthesiology in medical schools and hospitals should be in charge of a certified specialist in anesthesiology who should have direct supervision of the teaching of this subject to undergraduates and graduates. Albany Medical College, the University of Georgia, Stanford University, and the University of Vermont soon thereafter appointed certified specialists in anesthesiology to head these departments.

In 1938, the educational committee of the society set up a placement bureau for physicians desiring resident appointments in approved residency programs. It also announced short refresher courses in postgraduate instruction and listed hospital and medical school appointments in anesthesiology. The number of approved hospital residencies rose from 10 in 1933 to 49 in 1945. At the listing of approved hospital residencies in the Sept. 25, 1954, issue of THE JOURNAL of the American Medical Association, the number had risen to 188. The latest questionnaire sent to medical schools in 1954 showed that only 11 had autonomous departments in anesthesiology. The remaining departments are divisions or sections of surgery. All the chiefs of anesthesiology hold professorial rank, but of varying status (fig. 2).

The final objective of the founders' group was to bring the medical anesthetist to equality with the other specialists in medicine. From 1915 to 1934 the New York Society of Anesthetists, at various times, tried to get the public health law of the state of New York amended to include the administration of anesthetics in the practice of medicine. In 1939, when the anesthesia society was national in name as well as fact, it suggested that the problems of amending state laws for the practice of medicine and of working on the various phases of economic or legal practices, including hospital insurance plans, could best be handled on a local level. A number of state sections of the American Society of Anesthetists were thus set up for this purpose. In addition, it was planned to hold scientific meetings.

LATER DEVELOPMENTS

During World War II, there was a curtailment of activity, since many of the members were in the armed forces. The Articles of War of the Army and Navy Regulations had been revised to recognize the specialty of anesthesiology. Standard colors for the gas cylinders were achieved in 1942. Work on fire and explosion hazards was limited by the war needs. The major manufacturers agreed to standardize equipment. In April, 1945, the society changed its name to the American Society of Anesthesiologists, Inc. It also established an annual Distinguished Service award. As the end of the war neared, there were 739 members in the armed forces. A large number had become interested in anesthesiology while in service. They were concerned particularly in the plans of the society to increase the residency programs in anesthesiology. A further impetus to attract these men into the specialty was the declaration by the House of Delegates of the American Medical Association that the administration of anesthetics was within the practice of medicine. The final objective had been achieved.

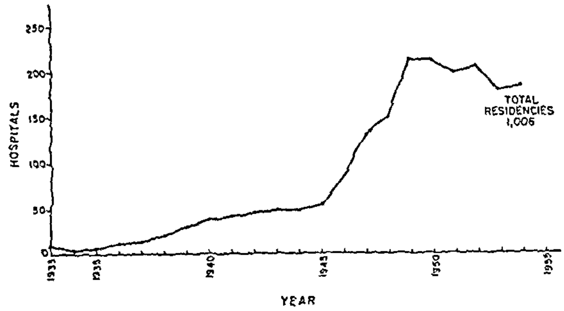

Fig. 2.—Rise in approved hospital residency programs in anesthesiology.

In 1946, the society had 2,147 members. Returning veterans found residencies in 63 training centers. Temporary approval of the residency programs of hospitals was granted to accommodate about 700 men who had been separated from the service. The first fellowship in anesthesiology given by the National Research Council was awarded in September of that year. The Morton Centennial and the Ether Centenary were celebrated in Boston in October under the aegis of the American Society of Anesthesiologists. By 1947, the realization that the society had expanded into an organization of over 2,400 members prompted the appointment of a permanent executive secretary as coordinator for activities. A new constitution and bylaws were adopted, providing for government of the society by the executive committee, a board of directors representing geographical regions of the United States and Canada, and a house of delegates composed of representatives from each state, the territories of the United States, and the provinces of the Dominion of Canada. The first annual meeting in which the house of delegates met was the St. Louis meeting in November, 1948. It heralded the coming-of-age of the society. A speaker and vice-speaker were added in 1953.

The new constitution also provided for component societies on state, territorial, and provincial levels. Each state society patterned its constitution after that of the parent society and, with the receipt of a charter, was allotted representation in the house of delegates. The formation of these component societies has provided a means of handling problems on a local level and of solving matters peculiar to a particular region. One of the important revisions in the new constitution was the establishment of the American College of Anesthesiologists. It was to be under the control of the society and replaced the committee on fellowship. This committee, set up in 1936 to certify anesthesiologists as fellows, became virtually inactive after the establishment of the American Board of Anesthesiology. It had been intended to continue designating as fellows in anesthesiology those anesthetists who could not qualify for the American Board of Anesthesiology and yet deserved some type of certification. When the American College of Anesthesiologists was set up in 1947, the members of the dormant fellowship committee became its board of governors. All anesthesiologists holding certificates previously issued by the committee automatically became fellows of the American College. From 250 fellows in 1947, the membership has steadily increased until there are now 1,335 fellows certified by the American College of Anesthesiologists. It has encouraged physicians to enter the specialty, enabled them to attain a high degree of competent safety, and provided a category of recognition for those who are qualified but do not limit their practice to the specialty of anesthesiology. In addition, the American Society of Anesthesiologists compiles a list of short postgraduate courses of instruction for physicians interested in part-time practice of anesthesiology as well as refresher courses at its annual meetings. The former list, from 110 centers of instruction, is sent each year to the American Academy of General Practice. General practitioners who enroll for these approved courses are given credit by the academy.

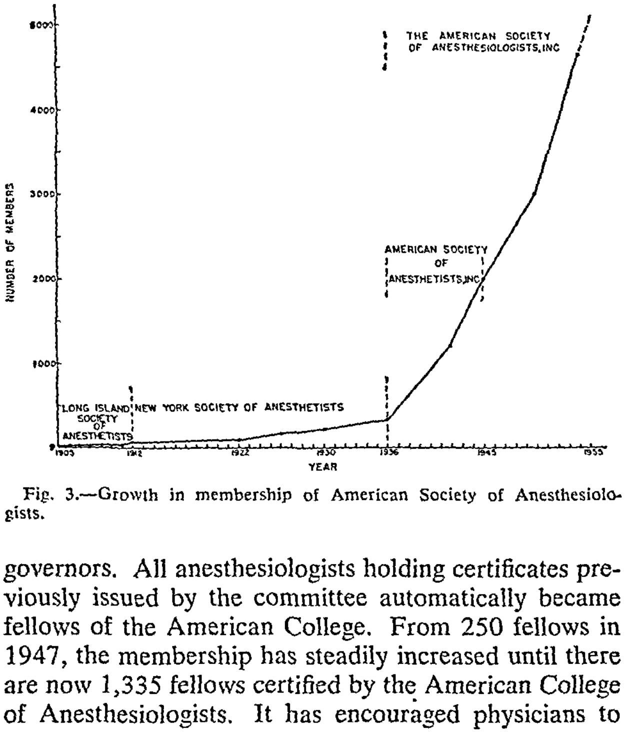

Fig. 3.—Growth in membership of American Society of Anesthesiologists.

The library-museum of the society, officially opened in 1937, has gradually added to its material until it now has available more than 800 exhibit pieces, 4,000 reprints, and 1,600 books. At the direction of the house of delegates at the 1949 annual meeting, a nonprofit organization, called the Wood Library-Museum of Anesthesiology, was formed. It is the official repository for the archives and equipment pertaining to anesthesiology of the American Society of Anesthesiologists and receives a yearly grant from the society.

PRESENT STATUS

Today we have an organization that has grown from a membership of 9 in 1905 (fig. 3) to a membership of 4,714, the Section on Anesthesiology in the American Medical Association, the American Board of Anesthesiology, the American College of Anesthesiologists, a library-museum, a journal of anesthesiology, and training standards in the medical schools and hospitals to elevate the status of anesthesiology and increase the measures of safety for the patient. The functions of the society are reflected in the set-up of its committees and subcommittees, which number more than 29 standing and special committees. Other special committees are appointed as the need for a new activity or as a problem arises. After 50 years of striving to achieve the goals of the founders, namely, to elevate the status of the physician-anesthesiologist and to safeguard the patient during surgery, have we achieved the maximum result? What is the future of organized anesthesiology? Perhaps we can find the answer in the president's address at the 1954 annual meeting of the American Society of Anesthesiologists in Cincinnati. He predicted that the membership of the society would double in the next 10 years, due to the increasing demand for anesthesiologists and the continued expansion of the nation's medical schools; that it would be necessary to install a board of trustees of the American Society of Anesthesiologists; and, finally, the most important, that the economic and professional status of the anesthesiologist would be established in the next decade, in a respect similar to that of any other physician in the clinical practice of medicine. Furthermore, just as the obstetrician has replaced the midwife, the anesthesiologist will replace the technician of anesthesiology within the next generation.

1435 Lexington Ave. (28) (Dr. Betcher).

Tricuspid Stenosis.—Recent reports of surgical treatment of tricuspid stenosis emphasize a need for an accurate method of diagnosing this lesion, which is difficult to recognize clinically, since it is usually overshadowed by mitral stenosis which invariably accompanies it. Although there are clinical signs suggestive of tricuspid disease, such as pigmentation of the skin, peripheral cyanosis, abnormal jugular venous pulsations, expansile pulsation of the liver, ascites in the absence of pulmonary congestion, murmurs in the tricuspid area, enlargement of the heart to the right, and abnormal P waves in the electrocardiogram, it is still difficult, even with the evidence provided by these signs, to make a confident diagnosis of tricuspid stenosis. However, Wood and Chesterman and Whitaker have described a means of diagnosing tricuspid stenosis from an abnormal blood pressure gradient between right auricle and ventricle. Recently, blood pressures similar to those described by these authors have been recorded in three patients who were found subsequently, at operation or autopsy examination, to have severe tricuspid stenosis, thus confirming that an abnormal blood pressure gradient across the tricuspid valve is a valuable sign of tricuspid stenosis.—Whitaker, William, M.D., M.R.C.P., The Diagnosis of Tricuspid Stenosis, *American Heart Journal*, August, 1955.

ESTIMATION OF TOTAL CIRCULATING SODIUM

Carroll M. Leevy, M.D.
and
Francis J. Donovan, M.D., Jersey City, N. J.

Studies of total circulating hemoglobin and protein[1] suggest that a similar quantitation of plasma sodium might be helpful in patients with sodium imbalances. This is a preliminary report of plasma volume and serum sodium determined simultaneously in patients with clinical evidence of water and electrolyte disturbances. These investigations indicate the desirability of knowing the state of the plasma volume as well as concentration of sodium for optimum diagnostic and therapeutic perspective in patients with suspected alterations of circulating sodium.

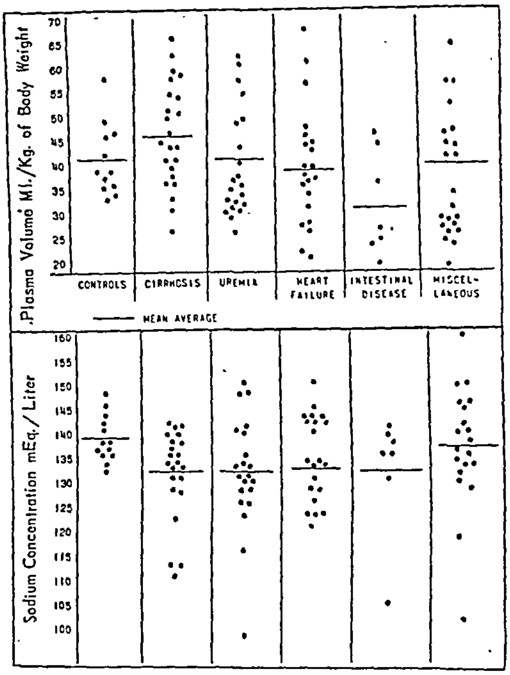

Fig. 1.—Plasma volume (top) and serum sodium concentration (bottom) studies on 13 control patients and 92 patients with body sodium abnormalities.

MATERIALS AND METHODS

Studies were performed on 13 normal subjects and 92 patients with body sodium abnormalities. Fluid and electrolyte disturbances were due to cirrhosis of the liver in 22 patients; heart failure in 21 patients; renal insufficiency in 21 patients; systemic disease with dehydration, fluid accumulation, or acid-base imbalance in 21 patients; and intestinal disease in 7 patients. Plasma volume was determined with standardized Evans blue, T-1824, by use of a modification of the method of Gregersen.[1] Plasma concentration of Evans blue was measured with an Evelyn spectrophotometer in specimens obtained without stasis 10 minutes after injection of the dye. The serum sodium level was determined with the Janke flame photometer by the indirect method. The total circulating sodium value was obtained by multiplying sodium concentration in milliequivalents per liter by plasma volume in liters.

OBSERVATIONS

Plasma volume ranged from 32 to 50 ml. per kilogram of body weight; serum sodium concentration varied from 134 to 148 mEq. per liter; and total circulating sodium ranged from 4.5 to 8.0 mEq. per kilogram of body weight in normal subjects. There was no specific pattern of plasma volume or serum sodium concentration characteristic of the disease states studied (table 1).

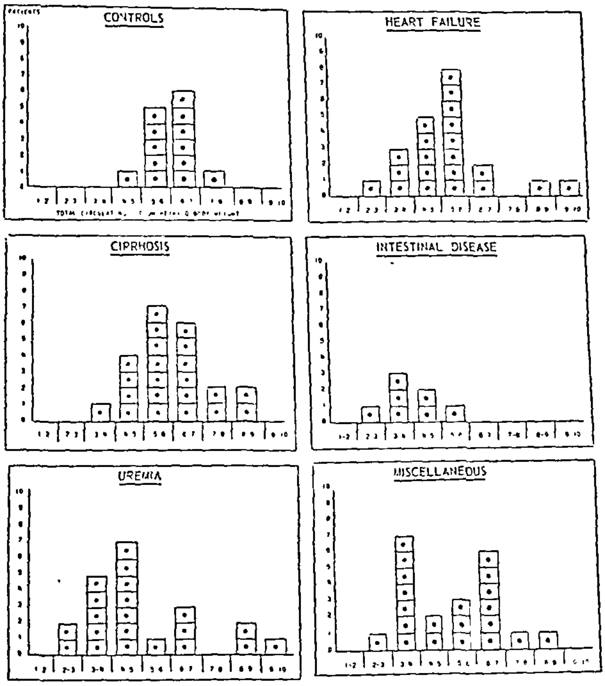

Fig. 2.—Average total circulating sodium in 13 control patients, 22 patients with cirrhosis, 21 with uremia, 21 with heart failure, 7 with intestinal disease, and 21 with miscellaneous systemic disease.

The plasma volume (fig. 1, top), serum sodium concentration (fig. 1, bottom), and average total circulating sodium (fig. 2) varied considerably. Symptoms were usually correlated with circulating sodium. Marked decrease in total circulating sodium was associated with hypotension, oliguria, and azotemia. These symptoms were rarely present with alterations in concentration of serum sodium or plasma volume if total circulating sodium was normal. Estimation of circulating sodium was found to be of practical help in the diagnosis and treatment of salt depletion, salt or water intoxication, and dehydration.

From the Department of Medicine, Jersey City Medical Center. Dr. Leevy is now a lieutenant commander in the United States Naval Reserve at St. Albans, Long Island, N. Y. Dr. Donovan is now in Boston.

Miss Mary L. Nemshick gave technical assistance in this study.

[1] Gregersen, M. I.: Blood Volume, Ann. Rev. Physiol. **13**: 397, 1951.

Simultaneous study of plasma volume and serum sodium concentration is valuable in deciding whether decreased serum sodium concentration is principally due to body salt depletion, shift of sodium into cells in response to potassium depletion, or primary water retention. This is an important decision in an acutely ill person such as the "waterlogged" nephritic patient, the patient with cirrhosis of the liver in hepatic coma, or the cardiac patient after operation. The total circulating sodium is usually low in uncomplicated salt depletion in contrast to a normal level in sodium redistribution and a normal or increased level in primary water retention. Estimated circulating sodium gives a base line for repair of hyponatremia and permits objective evaluation of the effectiveness of therapy. Hypertonic saline is the treatment of choice in patients with low serum sodium levels due to salt depletion [2] (table 2, case 1); however, it is contraindicated in other causes of hyponatremia. Failure to differentiate hyponatremia due to salt depletion and hemodilution may contribute to the high mortality reported in the low-salt syndrome.[3] Treatment of decreased serum sodium concentration, which occurs with negative potassium and nitrogen balance, consists of correcting the etiological mechanism and replacing deficient potassium and protein.[4] Fluid restriction corrects hyponatremia due to primary water retention (table 2, case 2).

TABLE 1.—*Average Values of Simultaneous Determination of Plasma Volume and Serum Sodium*

	Plasma Volume, Ml./Kg.	Serum Sodium Concentration, mEq./Liter/Kg.	Total Circulating Sodium, mEq./Kg.
Normal subjects	41.5 ± 5.2	139.1 ± 0.3	6.0 ± 0.7
Congestive heart failure	39.3 ± 9.4	138.3 ± 6.1	5.2 ± 1.2
Hepatic cirrhosis	45.2 ± 7.9	132.1 ± 6.3	6.0 ± 1.1
Uremia	39.9 ± 9.1	132.6 ± 7.9	5.1 ± 1.4
Intestinal disease	31.1 ± 9.0	132.9 ± 8.5	4.1 ± 0.9
Miscellaneous	37.6 ± 10.7	137.9 ± 8.4	5.2 ± 1.4

Estimation of total circulating sodium permits recognition of salt depletion, although the concentration of serum sodium remains normal. Uncomplicated loss of body salt is rarely accompanied by changes in serum sodium concentration. This is due to activity of osmoceptors that maintain normal concentration.[5] Hyponatremia is noted in patients with salt depletion when hemodilution occurs in response to the body's effort to maintain an adequate plasma volume.[6] A normal serum sodium concentration may mislead the clinician. Better insight is provided by study of plasma volume in addition to serum sodium concentration. We have found it desirable to determine the total circulating sodium repeatedly in patients with fluid retention refractory to therapy. This is illustrated by a patient with heart failure treated with the rice and fruit diet and daily mercurial diuretics. She developed anorexia, hypotension, oliguria, and an elevated nonprotein nitrogen level during the course of therapy. The low-salt syndrome was suspected; however, her serum sodium concentration remained within the normal range. The total circulating sodium was reduced from 7.7 mEq. to 3.9 mEq. per kilogram of body weight. The circulating sodium estimation provides a guide for treating salt depletion when serum sodium concentration remains normal (table 2, case 3). It has also been valuable as a method of determining the need for sodium bicarbonate or lactate in metabolic acidosis. These salts are contraindicated in renal insufficiency or diabetic coma if the circulating sodium level is normal or increased. Given under these circumstances, they do not improve the acidotic state and may induce further electrolyte imbalance and precipitate salt intoxication (table 2, case 4). Alkali may be lifesaving where there is a low serum pH accompanied by a decrease in circulating sodium.[7]

TABLE 2.—*Data Illustrating Value of Simultaneous*

				Laboratory Results			
				Plasma Volume, Ml./Kg. of Body Weight		Serum Sodium, mEq./Liter	
Case No.	Disease State	Treatment Given	Clinical Results	B *	A †	B	A
1	Laennec's cirrhosis with low-salt syndrome and hepatic coma	Hypertonic saline	Hepatic coma disappeared	32.2	42.3	118.8	144.8
2	Congestive heart failure with fluid retention refractory to sodium restriction and diuretics	Water restriction	Fluid mobilized and hyponatremia controlled	66.0	56.4	127.6	138.0
3	Heat exhaustion with peripheral vascular collapse	Isotonic saline	Disappearance of symptoms and signs of salt depletion	29.1	42.7	141.7	137.9
4	Renal insufficiency and acidosis due to chronic pyelonephritis	Molar sodium lactate	Production of hyperelectrolytemia and pulmonary edema	56.2	85.1	142.2	141.0

* B—Before therapy. † A—After therapy.

Study of total circulating sodium has facilitated the differentiation of hypernatremia due to dehydration [8] from the elevated serum sodium level seen in salt intoxication and from the physiological elevation of serum sodium level occasionally noted in central nervous system and endocrine disorders. The circulating sodium level is normal in dehydration, whereas it is increased in other causes of hypernatremia. This distinction is

helpful when an elevated serum sodium level occurs during the course of parenterally given fluid therapy or in association with other electrolyte disturbances.

COMMENT

It has been shown that there is no correlation between total exchangeable sodium and serum levels [9] and that a variety of factors influence body sodium economy. New methods of study have reemphasized the necessity for concern with abnormalities of both extracellular and intracellular electrolytes and stress the danger of dealing with one compartment without considering exchanges. Ideally it would be helpful to know the sodium content of the interstitial area and body cells as well as the plasma. It is now possible to obtain such information by combining results of volume assays and isotopic dilution studies. Further refinement of available techniques may provide a simple and accurate means to serially quantitate all body electrolytes.

It is agreed that no single laboratory test is as helpful as general clinical appraisal in recognition and treatment of sodium imbalances. Estimation of total circulating sodium provides a practical addition to current methods of study. Quantitative study of urinary sodium has been employed to evaluate the state of body sodium and interpret serum sodium alterations.[10] Fluctuations of adrenal reserve and renal function often independently alter urine sodium and limit usefulness of this type of study in patients requiring emergency therapy.

The reliability of either Evans blue or iodinated human serum albumin methods for study of plasma volume [11] and the availability of serum sodium by flame photometry make estimation of total serum sodium a practical procedure. Constant cognizance must be had of technical limitations and errors inherent in the procedures as performed. Serial determinations are more helpful, as they provide insight into long-range adjustments. Repeated use of Evans blue was accompanied by an untoward reaction in two patients in this series. These patients developed an anaphylactoid reaction that subsided spontaneously.

The clinician must be aware of disturbances of protein, water, and other electrolytes in evaluating total circulating sodium. After demonstrating an abnormality in circulating sodium, the decision as to what treatment, if any, is desirable depends upon the causative mechanism and the general metabolic state.

SUMMARY

Estimation of total circulating sodium by simultaneously determining serum sodium and plasma volume revealed a value of 6.0 mEq.±0.7 per kilogram of body weight in normal subjects. Specific disease processes are not associated with a characteristic pattern. Values range from a low of 3.0 mEq. per kilogram in salt depletion to a high of 12.4 mEq. per kilogram in salt intoxication. The total circulating sodium estimation may permit differentiation of hyponatremia due to salt depletion and primary water retention when one of these mechanisms is principally responsible for a decrease in concentration of serum sodium. It facilitates recognition of plasma sodium deficits with normal serum concentration of this ion. This type of study has improved therapeutic perspective in patients requiring prolonged treatment for fluid and electrolyte disturbances. Quantitation of circulating sodium appears to be a valuable adjunct to history, physical examination, and other fluid and electrolyte measurements in diagnosis and treatment of serum sodium disturbances. Constant cognizance of its limitations is essential to proper use in clinical medicine.

Determination of Plasma Volume and Serum Sodium

Reaction of Patient to Chronic Disease.—A patient enters a chronic illness as [he would] . . . a *foreign land. He can no* longer orient himself by accustomed landmarks; he has given up his own routines of living; and in so far as his usual symbols of communication take on new meanings and new references, he must even learn a new language. The reactions of patients with tuberculosis have been given considerable study. It has been recognized that they are in a sense uprooted people, isolated from their past and current life environments, not only by their infection and by the nature of their sanitarium experience, but as much by their own sense of difference from those with whom they have lived in intimate association. They may have reactions of sensitivity and defensiveness; they may become alert to rejection, fearful of their dependent needs, and angry with the unsympathetic world they project as an image on the screen of their preceptions.—J. V. Coleman, M.D., Attitudes of Professional Personnel in the Treatment of the Tuberculosis Patient, *American Journal of Public Health,* July, 1955.

CLINICAL RESULTS OF SELECTIVE LEUKOTOMY BASED ON INTRACEREBRAL ELECTROGRAPHY

Magnus C. Petersen, M.D., Henry W. Dodge Jr., M.D., Carl W. Sem-Jacobsen, M.D., Jorge A. Lazarte, M.D.
and
Colin B. Holman, M.D., Rochester, Minn.

Since Feb. 27, 1940, a total of 503 mentally ill patients have undergone prefrontal leukotomy at the Rochester (Minn.) State Hospital. The open method of Lyerly [1] has been used exclusively. The early operations were graded 4 on the scale devised by Love.[2] As much as possible of the white matter was cut in the plane of the coronal suture. Undesirable after-effects, such as inertia, confusion, and untidiness, always were in evidence after the operation. Most of the patients tended to become obese, and in many some masking of the facies developed. In order to prevent or to minimize these unpleasant sequelae, the trend has been to cut less extensively.[3] In all cases, the cut has been made in the plane of the coronal suture. Therefore, the variations have been in the extent and in the location of the cut in this plane.

STUDY OF ELECTRICAL POTENTIALS

In 1949 a study of the electrical potentials encountered in the depth of the frontal lobe in man was commenced.[4] The recordings were made in the operating room on patients undergoing prefrontal leukotomy. Disadvantages resulting from time limitations, from changes in potentials caused by surgical trauma, from the introduction of a rather bulky electrode, and from anesthetic agents soon became evident. Many of the difficulties were overcome by changes in procedure made possible by replacing the electrodes then in use with flexible electrodes. These could be implanted and left in position for long periods of time before the leukotomy was performed.[5] Thus, the pattern, properties, and distribution of electrical rhythms encountered in the depth of the human brain could be studied in the laboratory under controlled conditions.[6] In this manner electrical potentials in the frontal lobes of 73 patients have been studied through 2,294 recording tips. In the plane of the coronal suture, waves of 2 to 4 cps were invariably recorded from a circumscribed area in the ventromedian quadrant of the frontal lobe. The size of this area, in most cases, varied from 1 to 2 cm. in diameter. The location was fairly constant but varied slightly from patient to patient. It should be emphasized that these wave forms, which are considered abnormal by conventional surface electroencephalographic standards, were always encountered in depth but were not seen in recordings from the scalp.

The finding in the ventromedian quadrant of the frontal lobe of a circumscribed area having a specific electrical activity induced us to limit the cutting to this region. Since July 14, 1953, this selective prefrontal leukotomy has been performed on 63 mentally ill patients. Fifteen of them were male and 48 were female. They ranged in age from 16 to 72 years. Three were below 20 years of age and 47 were between 20 and 49 years of age, while 13 were 50 years of age or older; the average age was 38.1 years. The duration of the mental illness varied from 1.5 to 36 years, the average being 9.4 years. These patients had been hospitalized continuously for periods of time varying from three months to 35 years, the average being 5.5 years.

* S. A. = social adjustment; M. I. = much improved; S. I. = slightly improved; N. I. = not improved.

CLINICAL RESULTS

The clinical results as of Nov. 12, 1954, are summarized by diagnoses in the table. The evaluations were made from personal observations, from reports submitted by relatives of the patients, or from both. By "social adjustment" is meant that the patient has been dismissed from the hospital and has resumed his or her place in society. The patients classified as "much improved" may be either in or out of the hospital. If they are out of the hospital, they are still in need of guidance and some supervision. If they remain in the hospital, they require but little supervision, and usually they are good workers. By "slightly improved" is meant that the patient is more pleasant, less disturbed, and in better contact with reality than he was before the leukotomy. The term "not improved" is self-explanatory.

From the Mayo Foundation, the Rochester State Hospital (Drs. Petersen, Sem-Jacobsen, and Lazarte), and the Mayo Clinic (Drs. Dodge and Holman).

Read before the Eighth Clinical Meeting of the American Medical Association, Miami, Fla., Dec. 2, 1954.

The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

The studies in intracerebral electrography have been supported in part by a research grant from the Minnesota Department of Public Welfare.

As shown in the table, 14 (22.2%) have made satisfactory social adjustment and 37 (58.7%) are much improved. Thus, 51 (80.9%) can at this time be classified under the heading of good results. Nine persons, so far, have shown little or no improvement. One of them is mentally deficient and possibly epileptic, one suffers from congenital athetosis and psychosis, and two have psychosis with hereditary chronic progressive chorea with mental deterioration (Huntington's chorea). At this time, 16 are out of the hospital. Three very disturbed patients died.

REPORT OF CASES

Case 1.—A divorced woman, 38 years old, was first hospitalized for mental illness in 1945. Her main complaints were that people in some mysterious manner were harming her, causing her eyes to burn, and giving her headaches. She improved under electrotonic treatment but did not fully recover. She was again hospitalized in 1951 and 1952. On both occasions she improved in response to electrotonic treatment. Insulin treatment also was given in 1952. The improvement was short-lasting, however, and the complaints gradually became more pronounced, necessitating further hospitalization in March, 1953. The patient was admitted to the Rochester State Hospital on April 6, 1953. At that time she complained that people in some way were harming her through the electrical wires in any building where she happened to be. This caused her to have headaches and a severe burning pain in the eyes. She insisted that the FBI be notified, since she had previously reported the matter to that agency. She continuously kept both eyes covered with black cloth, even though the ophthalmologist assured her that there was nothing organically wrong with them. Between May 20, 1953, and July 1 of that year the patient had 15 electrotonic treatments. Mentally she improved, but she promptly relapsed when the intervals between treatments were lengthened. For this reason a selective prefrontal leukotomy was performed on July 14, 1953. Intracerebral electrographic studies were made before the operation was performed. On the basis of information derived from these studies it was decided to limit the cutting to the lower medial quadrants. She responded readily and was dismissed from the hospital as recovered on Aug. 17, 1953. On Aug. 28 she resumed her former position of secretary in a business establishment.

Case 2.—In 1945 a 31-year-old married woman began to have spells during which she would stare into space, cry out loudly, and complain that people were spying on her. She was admitted to a hospital and given electrotonic treatments. She improved temporarily, but further hospitalization and treatment became necessary in 1946, in 1947, and again in 1948. The response to treatment was essentially the same in each instance. In December, 1948, the patient became very disturbed, destructive, and violent. On one occasion she struck her husband with a bottle while she was riding with him in the family car. On another occasion she grabbed the steering wheel of the car when they were driving and at the same time tried to bite her husband, who was at the wheel. The patient was admitted to the Rochester State Hospital on Jan. 7, 1949. Mentally she was confused, and there was much blocking. She responded to electrotonic treatment but did not fully recover. She was home on two occasions but in each instance was returned to the hospital after a few months in essentially the same mental condition described on her first admission. A prefrontal leukotomy of the selective type was performed on Sept. 8, 1953. Preceding the operation intracerebral electrographic studies were made. As a result of these studies, it was decided to cut the medial half of the left frontal lobe and the lower medial quadrant of the right. The patient responded well to the operation and was dismissed from the hospital as recovered on Jan. 23, 1954. She is working as a saleslady and has made a good social adjustment in spite of an unsatisfactory home situation.

Case 3.—A single girl, 19 years of age, was admitted to the Rochester State Hospital on June 11, 1953. She was born prematurely and was said to have always been sensitive, nervous, and withdrawn. As a child she had frequent temper tantrums and had the habit of nail-biting. She repeated the first grade in school but completed the 12th grade in 1952. The onset of the mental illness was insidious. In December, 1952, the symptoms became more pronounced. The patient showed poor judgment in that she spent her money foolishly, would throw good clothing away, and would let herself be picked up by strangers. On admission to the hospital the patient was slow and preoccupied. When spoken to, she would hide her face in her hands and arms; she would not answer questions unless she was coaxed. Between June 17, 1953, and Nov. 4 of that year she received 26 electrotonic treatments. She gained a great deal in weight and improved much mentally. The improvement was not sustained. Soon the patient again became preoccupied and would laugh in a silly and inappropriate manner. A selective prefrontal leukotomy was performed on March 23, 1954. On the basis of information gained from intracerebral electrographic studies made before the leukotomy, it was decided to limit the cut to the lower medial quadrants. There was steady improvement after the operation, and she was dismissed on June 15, 1954, as much improved. Her social adjustment at the time of writing is good.

COMMENT

Observation of a larger number of patients over longer periods of time is necessary before a final evaluation can be made of this selective leukotomy. It can be stated, however, that so far the clinical results are better and the undesirable after-effects are fewer than they were after the more extensive types of leukotomy.

1520 E. Center St. (Dr. Petersen).

CLINICAL NOTES

EVALUATION OF A RAPID SERUM AMYLASE TEST

Michel Gilbert, M.D., Rochester, N. Y.

The purpose of this paper is to report our experience at the Strong Memorial Hospital with the rapid serum amylase test described by Fishman and Doubilet.[1]

METHOD

The amylase activity is estimated in Somogyi units by incubating a small amount of serum with a minute quantity of starch at 40 C (104 F) for five minutes. The residual starch, if any, is measured by the color changes produced by the addition of an iodine reagent. The test was found suitable for emergency clinical conditions, since the only equipment needed was a constant temperature water bath, a centrifuge, small test tubes, pipets, and three dropping bottles. The reagents, described in the original article, were simple to prepare and needed few precautions to maintain in suitable condition.

During the period of January to July, 1954, this test was employed in our surgical emergency ward in all cases of acute upper and midabdominal distress of doubtful etiology. The remaining serum was rechecked later by the Somogyi method. In the absence of correlation of the results, the Somogyi test was repeated in order to rule out an error in the latter method.

From the Department of Surgery, University of Rochester, Strong Memorial Hospital. Dr. Gilbert is now at the University Hospitals, Cleveland.

[1] Fishman, L., and Doubilet, H.: A Rapid Serum Amylase Test, J. A. M. A. 157:908 (March 12) 1955.

RESULTS

A total of 56 emergency tests were performed; however, 6 of these were not checked by the Somogyi method and thus had to be discarded from the series. Of the remaining 50 results, 3 did not correlate with the Somogyi method, an error of 6%. Of the 47 patients whose serum amylase levels were found to be correct, the range was as follows (see table): 4 patients (8.5%) had serum amylase levels greater than 500 mg. per 100 cc., 5 patients (10.5%) had serum amylase levels between 350 and 500 mg. per 100 cc. Thus, 9 patients (19%) out of the 47 had a definite elevation of their serum amylase. Eight patients (17%) had a serum amylase level between 200 and 350 mg. per 100 cc., and 30 patients (64%) had a normal serum amylase level (0 to 200 mg. per 100 cc.).

COMMENT

Pancreatitis, either primary or secondary to other pathology (e. g., posterior penetrating ulcer), is often difficult to diagnose clinically unless a serum amylase test is done during the acute phase. The results on the 47 patients with acute upper or midabdominal pain of unknown etiology seen in our emergency ward showed that 9 patients (19%) had a definitely elevated serum amylase. These nine patients were given a diagnosis of acute pancreatitis and were treated by active nonoperative measures such as nasogastric suction, parasympatholytic agents, and infusions. Further tests such as gastrointestinal and gallbladder series were performed later to rule out the possibility of pancreatitis being secondary to other pathology. Thus, a little less than one out of five patients seen in our emergency ward with upper or midabdominal distress of doubtful etiology had pancreatic involvement.

Range of Serum Amylase Levels (in Somogyi Units) in Forty-Seven Patients with Acute Upper or Midabdominal Pain of Unknown Etiology

Amylase Range	Patients No.	Patients %
Elevated		
> 500 mg. per 100 cc.	4	8.5
350 to 500 mg. per 100 cc.	5	10.5
Doubtful range		
200 to 350 mg. per 100 cc.	8	17
Normal range		
0 to 200 mg. per 100 cc.	30	64

The test developed by Fishman and Doubilet was found to have a 94% accuracy and did not require any expensive or intricate equipment or trained personnel. Determination of the amylase level required only five minutes after the blood was clotted. Although only the range (e. g., 0 to 200, 200 to 350, 350 to 500, 500 to 700, and greater than 700 mg. per 100 cc.) and not the exact amylase content was given, this sufficed for emergency use. A more exact amylase concentration could be determined later with Somogyi method. Another advantage of this test was the small amount of serum needed (e. g., 0.1 cc. and 0.05 cc.). For example, the amylase content of even a few drops of fluid obtained by paracentesis could be easily determined. The color and end-points were found to be sharp and their interpretation easily made (e. g., blue to green, 0 to 200 mg. per 100 cc.; light green or amber, 200 to 350 mg. per 100 cc.; yellow, 350 mg. per 100 cc. or higher). If a yellow color was obtained with the use of 0.1 cc. serum, then another tube was set up with only 0.05 cc. serum and the results interpreted as follows: blue to green, 350 to 500 mg. per 100 cc.; orange to amber, 500 to 700 mg. per 100 cc.; yellow, 700 mg. per 100 cc.; or higher. The only difficulty we encountered was to remember that the starch solution had to be made up every three weeks and kept refrigerated when not in use. It was found that two of our three errors were due to the use of a starch solution older than three weeks. Since that time, by using a starch solution no older than three weeks, 24 consecutive serum amylase determinations have been made without error as determined by comparisons with the Somogyi method. It was also found necessary to change the iodine reagent every four months in order to have sharp color end-points.

SUMMARY

The rapid serum amylase test described by Fishman and Doubilet was found to be of value as an emergency procedure in the differential diagnosis of acute upper abdominal conditions and has been adopted at our hospital for this use.

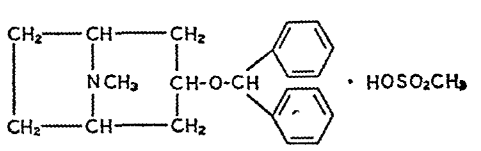
COUNCIL ON PHARMACY AND CHEMISTRY

NEW AND NONOFFICIAL REMEDIES

Monographs and supplemental statements on drugs that appear in this column have been authorized by the Council for publication and inclusion in New and Nonofficial Remedies. They are based upon the evaluation of available scientific data and reports of investigations.

R. T. Stormont, M.D., *Secretary.*

Benztropine Methanesulfonate.—$C_{21}H_{25}NO.CH_4O_3S$.—M.W. 403.52.—3-Diphenylmethoxytropane methanesulfonate. — Tropane benzohydryl ether methanesulfonate.—The structural formula of benztropine methanesulfonate may be represented as follows:



Actions and Uses.—Benztropine methanesulfonate, a parasympatholytic agent that comprises chemical features of both atropine and certain antihistiminic drugs, exhibits anticholinergic, antihistaminic, and local anesthetic properties. Its anticholinergic effect is useful in the symptomatic treatment of all forms of paralysis agitans. The therapeutic significance of its antihistaminic and local anesthetic actions in that disease or its over-all usefulness for other conditions has not been established. The action of benztropine methanesulfonate is prolonged; its anticholinergic effect is approximately equivalent to that of atropine sulfate; its antihistaminic activity is similar to that of pyrilamine maleate. Benztropine may be associated with anticholinergic-like side-reactions as well as the characteristic sedative and other side-effects of the antihistaminic drugs. Benztropine methanesulfonate does not produce central stimulation.

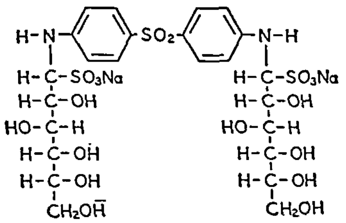
In paralysis agitans, benztropine methanesulfonate is chiefly effective for the relief of tremor and rigidity. It also may ameliorate other troublesome symptoms such as sialorrhea, drooling, mask-like facies, oculogyric crises, and pain secondary to cramping and muscle spasm. It may be employed alone or in conjunction with certain other drugs of established value in paralysis agitans, depending upon its effectiveness in individual patients. Aged patients who do not tolerate cerebral-exciting agents may respond to benztropine methanesulfonate.

Therapeutic doses of benztropine methanesulfonate may cause such anticholinergic-like side-effects as dryness of the mouth, blurred vision, nausea, and nervousness. Unless these effects are severe or are accompanied by vomiting or difficulty in swallowing or speaking, they usually can be disregarded or the dosage reduced slightly. In excessive doses for a given patient, the drug may cause weakness and inability to move particular muscle groups, which require adjustment in dosage. Difficulty in urination may be encountered occasionally, and the possibility of producing or aggravating glaucoma resulting from the mydriatic effect of the drug should be borne in mind. In the event of severe reactions such as mental confusion, excitement, or vomiting, the drug should be withdrawn temporarily and then resumed at a lower dosage level. Patients exhibiting a sedative side-effect, which may be associated with the accompanying antihistaminic action, should not be permitted to operate machinery or appliances requiring alert attention.

Dosage.—Benztropine methanesulfonate is administered orally. The usual dosage in paralysis agitans is 1 to 2 mg. daily, with a range of 0.5 to 6 mg. Patients should be started on a single daily dose of 0.5 to 1 mg. with increments of 0.5 mg. every few days until the optimal tolerated dosage is reached. The increments can be added as a separate 0.5 mg. dose so that doses of 0.5 mg., or multiples thereof, one to four times daily may be administered. Younger patients with post-encephalitic paralysis agitans may tolerate larger initial doses and, for maintenance therapy, may require 2 mg. two or three times daily. Older patients may be controlled by 1 mg. twice daily. Some patients may receive the greatest benefit with a single 2 mg. dose at bedtime, which is often sufficient to control symptoms for 24 hours; a single total daily dose administered at another time also may be effective for some patients. As with other therapy in paralysis agitans, the approach should be one of individual adjustment of dosage to obtain maximal symptomatic improvement with a minimum of undesired effects. When the drug is given to replace or supplement other drugs, the change should be gradual, with the dosage of the previous medication being reduced as the dosage for benztropine is increased.

Sharp & Dohme, Division of Merck & Co., Inc., cooperated by furnishing scientific data to aid in the evaluation of benztropine methanesulfonate.

Glucosulfone Sodium.—$C_{24}H_{34}N_2Na_2O_{18}S_3$.—M.W. 780.70. — *p,p'*-Diaminodiphenylsulfone-N,N'-di-(dextrose sodium sulfonate).—Glucosulfone sodium is available only in a mixture containing about 88.5% of anhydrous *p,p'*-diaminodiphenylsulfone-N,N'-di-(dextrose sodium sulfonate) and about 11.5% of dextrose. The structural formula of the active component may be represented as follows:



Actions and Uses.—Glucosulfone sodium is a chemotherapeutic agent effective against Mycobacterium. It is tolerated far better parenterally than orally, possibly because of liberation of the parent compound, *p,p'*-diaminodiphenylsulfone, by action of gastric acid.

The drug is effective in the treatment of leprosy. Against tuberculosis the results have been less dramatic, although beneficial effects have been reported. Streptomycin is much more effective in tuberculosis than is glucosulfone sodium, but, when the two are given together, development of resistance to streptomycin is delayed; hence in tuberculosis glucosulfone sodium is used principally as an adjunct to streptomycin therapy.

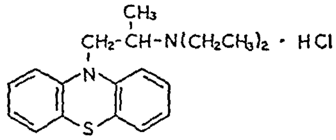
The most important untoward reaction to parenteral administration of glucosulfone sodium is the development of a hemolytic anemia. This usually corrects itself after discontinuance of the drug. Other toxic effects include nausea, vomiting, cyanosis, rashes, and mental confusion. These reactions may occur in about 10% of patients.

Dosage.—In the treatment of leprosy, the intravenous dose is 2 to 5 gm. It is administered daily for six consecutive days, omitted on the seventh day, and administered daily for the next six days. Treatment is interrupted for one week at the conclusion of each two week period. This schedule should be maintained for many months, the precise duration depending on the patient's response. In the treatment of tuberculosis, glucosulfone sodium may be used according to the same dosage schedule in conjunction with the usual course of streptomycin therapy.

Patients receiving glucosulfone sodium for prolonged periods should be under constant supervision. Frequent estimations of hemoglobin should be made and the drug stopped if any signs of anemia appear.

Parke, Davis & Company cooperated by furnishing scientific data to aid in the evaluation of glucosulfone sodium.

Ethopropazine Hydrochloride.—$C_{19}H_{24}N_2S.HCl$.—M.W. 348.93. — 10-(2-Diethylaminopropyl)phenothiazine hydrochloride.—The structural formula of ethopropazine hydrochloride may be represented as follows:



Actions and Uses.—Ethopropazine hydrochloride, a phenothiazine derivative, is a parasympatholytic agent that exhibits a ganglionic blocking action comparable to that of nicotine but that produces a sufficient depression of the central nervous system to block the convulsant activity characteristic of nicotine. Intense and prolonged mydriasis is produced by parenteral injection in experimental animals. The drug also antagonizes certain acetylcholine effects such as bradycardia, hyperperistalsis, and salivation but, unlike atropine, does not inhibit the hypotensive effects of acetylcholine. Except at high dosage levels, it has only a minor effect on blood pressure, and its adrenolytic activity is somewhat weak and variable. Small doses stimulate respiration, but larger doses depress respiration. The drug also exhibits some antihistamine activity.

Ethopropazine hydrochloride is useful in the symptomatic treatment of parkinsonism, especially for controlling rigidity. It also exerts a favorable influence upon spasm, tremor, sialorrhea, and oculogyric crises and festination in that disease and may be employed in conjunction with other appropriate atropine-like drugs when these are indicated to supplement the action of ethopropazine, such as in refractory oculogyric crises. The role of its antihistaminic action in parkinsonism has not been established.

Ethopropazine hydrochloride commonly produces side-effects, but these are rarely severe. High dosage may cause temporary hypotension. With therapeutic doses drowsiness is the most frequent side-effect and dizziness also may occur. As dosage is increased, mouth dryness, blurring of vision, lassitude, sense of heaviness in the limbs, and, less commonly, epigastric discomfort also may appear. Because of its mydriatic action, ethopropazine theoretically should not be used in patients with glaucoma. Administration of the drug over long periods has not been followed by any blood dyscrasias or other signs of chronic toxicity.

Dosage.—Ethopropazine hydrochloride is administered orally. Optimal effective dosage is determined by individual response and may change with progression of the disease. Patients with symptoms of mild to moderate severity frequently respond to a daily dosage of 0.1 to 0.2 gm., preferably administered in divided doses to provide a smooth, sustained effect of the drug. Severe symptoms may require gradual increase in the daily dosage to 0.5 or 0.6 gm. Daily dosage as high as 1 gm. has been employed without ill-effects, but it is seldom necessary to exceed a total of 0.7 gm. daily. Therapy is usually initiated with a dose of 10 mg. four times daily. This is increased 10 mg. per dose every two or three days until a dose level of 50 mg. four times daily is reached at the end of the second week of therapy. Further increments may be added as necessary so as to reach an optimal level within three weeks of therapy. In some patients a fifth dose at bedtime may be desirable or the morning dose may be larger than the subsequent doses for the day. When used to supplement or supplant other medication, the drug is added to the existing regimen by administering initial doses and gradual increments as stated previously for two weeks; then it is continued while the original medication is gradually reduced. It is then stabilized at a lower level or is eventually discontinued. Complete transition usually requires a period of about six weeks; replacement therapy should not be substituted suddenly.

With the occurrence of distressing side-effects, lowering of dosage may become necessary, but those effects encountered during initial stages of therapy usually disappear with continued medication. Unless uncomfortable side-effects are unusually severe, it is rarely necessary to discontinue therapy.

Warner-Chilcott Laboratories, Division of Warner-Hudnut, Inc., cooperated by furnishing scientific data to aid in the evaluation of ethopropazine hydrochloride.

Fibrinogen (Human).—Fibrinogen is a protein essential for blood coagulation. It is prepared by alcohol fractionation from human plasma collected and prepared in accordance with the regulations of the National Institutes of Health.

Actions and Uses.—Fibrinogen (human) is indicated for certain extensive surgical procedures and for restoring plasma fibrinogen levels to normal as an adjunct in treating hemorrhagic complications caused by acute afibrinogenemia. This latter condition often accompanies premature separation of the placenta (abruptio placentae). It is also used in the prevention of hemorrhagic episodes resulting from congenital or acquired chronic hypofibrinogenemia. Although the risk of transmitting serum hepatitis is probably greater with fibrinogen (human) than with whole blood, the amount of fibrinogen that can be supplied by whole blood transfusion is inadequate to restore fibrinogen levels in acute afibrinogenemia. Fibrinogen (human) should not displace the use of whole blood when the latter is indicated to replace the loss of formed elements or other components arising from the hemorrhagic complications of fibrinogen deficiency.

In the employment of fibrinogen (human) the physician should weigh very carefully the hazard of transmitting the virus of serum hepatitis against the danger of hemorrhagic complications in which it may be lifesaving. It should not be employed in the absence of adequate blood coagulation studies and determination of plasma fibrinogen levels, except in emergencies when facilities for performing these procedures are not available. A plasma fibrinogen level of less than 50 mg. per 100 cc. is considered critically low; levels below 100 mg. per 100 cc. may indicate the need for fibrinogen, but, in chronic hypofibrinogenemia, low levels may be encountered without frank hemorrhage.

Dosage.—Fibrinogen (human) is administered intravenously after reconstitution of a dried preparation with water for injection; 1 gm. of dried fibrinogen (human) is dissolved in 50 cc. of pyrogen-free sterile distilled water. The dried product should be stored at 2 to 10 C. It should be administered within one hour after reconstitution. In acute afibrinogenemia associated with premature separation of the placenta, the usual dosage is 2 to 6 gm. (100 to 300 cc.), depending upon the response of the patient. In other afibrinogenemic or hypofibrinogenemic conditions, the dosage should be adjusted according to the clinical observations and initial plasma fibrinogen levels. Whenever feasible, the latter are invaluable as an aid for determining the adequacy of the dosage.

Cutter Laboratories cooperated by furnishing scientific data to aid in the evaluation of fibrinogen (human).

COUNCIL ON FOODS AND NUTRITION

The following article adopted by the Council is published to explain in general terms the Council's new method of operation. EUGENE H. STEVENSON, M.S. *Acting Secretary.*

NEW COUNCIL PROGRAM

One of the responsibilities of the medical profession is to assist in the attainment and maintenance of a high level of nutritional health in our nation. The American Medical Association can best meet this responsibility in the following manner: (1) by formulating desirable nutritional standards for foods and expressing opinions regarding their wholesomeness and usefulness, emphasizing those foods that have public health significance or are important in the feeding of special population groups, such as infants, invalids, and others; (2) by indicating what it believes to be desirable criteria for the formulation of accurate and informative advertising copy pertaining to foods and nutrition; and (3) by reporting to the profession and educating the public on all aspects of nutrition through the dissemination of accurate nutritional information.

Therefore, the activities of the Council on Foods and Nutrition of the American Medical Association shall be directed toward these three objectives, as described below.

FOOD STANDARDS

Desirable standards for certain classes of foods will be developed and periodically reviewed and revised as needed.

In addition to standards for special purpose foods, standards for general purpose foods of public health importance, such as vitamin D milk, iodized salt, and citrus juices, will be developed. As other properties of foods are subject to regulation by the Food and Drug Administration and by the laws of individual states, the standards proposed by the Council will be directed toward the improvement of the nutritional aspects of foods.

These standards will be made available to the medical profession and others interested through periodic reports in THE JOURNAL and elsewhere.

The Council may publish in THE JOURNAL informational reports on the use of the Council standards and on the extent to which labeling laws protect the public from false or incorrect claims and the misuse of Council standards.

The Council proposes to determine from time to time by independent evaluation whether products claimed to meet Council standards actually do so and to call incidents of mislabeling to the attention of the appropriate authorities or the profession as indicated.

FOOD ADVERTISING

To guide those concerned with the production and marketing of nutritionally better foods, the Council is revising its publication, "General Decisions on Foods and Food Advertising." This includes statements and decisions of the Council on food composition, food advertising, and special food questions relating to public health. The Council believes that these will serve as valuable aids in the composition of accurate and informative advertising copy.

Educational food advertising (informative advertising dealing with classes of foods without reference to specific brands, processors, or distributors) will continue to be an interest of the Council. A program will be conducted as in the past except that a seal will not be granted. When an educational advertisement has been reviewed by the Council and found to be consistent with current authoritative medical opinion, permission will be granted to use a statement indicating this fact.

NUTRITION EDUCATION

The Council, since its inception, has recognized its responsibility of interpreting the findings of nutritional research and disseminating accurate nutritional information to the physicians and the public. Expansion of this activity has been under study for some time by a Council committee and has been carefully explored in discussions of the full Council. With the discontinuation of the seal-acceptance program, the Council can now devote more of its energies in this direction.

The program of nutrition education will utilize a variety of means of communication. It will provide a source of accurate information for presentation to the profession and the public in national and local programs. It will sponsor conferences on a high professional level on topics of current interest in the field of nutrition, such as the recent Symposium on Inorganic Elements in Human Nutrition. It will prepare educational material for medical publications and when requested check for accuracy suitable news releases for the public press. The program will provide for Council-sponsored articles for presentation in THE JOURNAL and other Association publications.

The program of nutrition education will provide nutrition information to other interested organizations at national, state, and local levels through corresponding medical channels. The presentation of nutrition information in medical schools can be facilitated greatly by this program.

PLACEBOS

Most dictionary definitions of a placebo are too restrictive for modern usage. Hofling [1] defines a placebo as a "therapeutic measure which is administered largely or entirely for a psychologic effect not inherent in its physical or pharmacologic properties." This definition does not limit usage to drugs. It is reasonable, for example, to speak of a heat treatment as having a placebo effect. Leslie [2] has classified placebos as pure when the effect is due entirely to their psychological effect and as impure when they contain a substance of some inherent pharmacological activity not relevant to the immediate problem. The patient's faith in his physician adds great psychic power to the efficacy of any therapeutic measure and makes the placebo an important adjunct to treatment. What constitutes a good placebo cannot be specifically stated, because what may be a good one for one patient may not be so for another even though he has a similar condition. However, anything that is so used must be inexpensive and nontoxic.[3]

Leslie defends the use of placebos on ethical grounds when they are used for the welfare of the patient. Sometimes a placebo may be needed as a stopgap to relieve distressing symptoms in a patient who must undergo prolonged diagnostic tests. There is always a danger in this situation that if the placebo works too well the physician will relax his efforts and miss a chance to treat disease in an early stage. An injection of sterile water for the patient after operation who is being weaned away from opiates may aid in preventing habituation. Surely it is as legitimate to give placebos for a condition that has been carefully diagnosed as it is to give them for one for which no scientific treatment exists. To tell a patient with such a condition that there is no help for him would be cruel and negligent. In dealing with patients whose dependent need for emotional security is great the physician may use placebos, not to deceive, but as an added emotional link with the patient. On the other hand, to give a placebo in order to quiet a patient at any cost indicates a negative approach to the real problem. It is poor practice to give a therapeutic agent as opposed to a pure placebo on the assumption that it can do no harm and may do some good. Vitamins are often given in this spirit, and if the patient appears to benefit the physician may come to think the improvement has been due to a specific effect of the placebo and may be tempted to use the same drug in treating a patient for whom a more specific treatment is available. To give vitamins to a well-nourished patient or injections of liver extract to one who is not anemic bespeaks an uncritical and confused state of mind in a physician.

A placebo should not be given when the physician-patient relationship is in jeopardy and not unless the physician has examined the indications for its use even more carefully than if he were to order specific therapy. Leslie gives many helpful suggestions regarding the technique of giving placebos. No placebo should be given for a prolonged period. If the placebo is in tablet form it should not look like aspirin in color, shape, or size. When withdrawing a placebo on which a patient has become dependent it will not help him to be told that it was only a placebo.

A special indication for the use of placebos is the double-blind test of the efficacy of a new drug, in which neither the physician nor the patient knows whether the patient is getting an active drug or a placebo. This sort of testing should keep the observations objective, but patients known as placebo-reactors, those who cannot discriminate clearly between active and inert drugs, have been found to exist.[4] A large number of such reactors in the control series would tend to decrease the difference between the results obtained with a potent and valuable drug and the controls, possibly to the point of indicating that the new drug was worthless. On the other hand, the optimal dosage of a drug may be underestimated if a large number of placebo-reactors whose symptoms are easily relieved by any medication have been included in the test group. This hazard sometimes may be overcome, if conditions permit, by making the patient his own control by giving drug A one time and drug B another time, one of these being the placebo and the other the drug being tested. If the symptoms of a chronic disease are being treated the test group and control group can be reversed at stated intervals, but if both groups contain many placebo-reactors the results may still be misleading. A complicating feature of this problem is that placebo-reactors are not consistent in their response. Studies are being conducted to try to enable experimenters to recognize and weed out placebo-reactors. This promises to be no easy task. Furthermore, it is difficult to evaluate the effect of drugs on a disease in which a large psychosomatic factor is present, such as peptic ulcer, hypertension, migraine, and scleroderma.

There are many legitimate uses for placebos, but physicians should use them wisely and avoid using them for any but the most carefully considered indications.

AWARD FOR A. M. A. COMMITTEES

The American Medical Association, through its Committee on Pesticides and Committee on Toxicology, has been awarded a national home safety Certificate of Commendation for exceptional public service in the prevention of home accidents during the year 1954-1955 by the National Safety Council. The award was bestowed for the committees' educational efforts to reduce accidental poisoning. The Committee on Pesticides studies the dangers involved in the use of agricultural chemicals, while the Committee on Toxicology investigates the health problems of household and industrial chemical products. The two committees conduct educational and research programs on two fronts: first, to increase public understanding of the proper use of chemicals; and, second, to provide guidance to the medical profession on the many health questions that are associated with the use of chemicals.

The older of these two groups is the Committee on Pesticides, which was formed in January, 1950. As part of its education program, it has prepared 20 interpretative statements reviewing the medical and public health aspects of agricultural chemicals. These have had worldwide distribution and have been translated into several foreign languages. An exhibit on accidental poisoning and a radio transcription on the same theme have been in constant demand by medical societies and lay health groups. The Committee on Pesticides has also encouraged greater consideration of economic poisons in the curriculums of medical and pharmacy schools by providing outlines of information, organizing symposiums, and arranging for experimental studies of pharmacologically interesting pesticidal compounds.

The Committee on Toxicology was organized more recently. It was set up early this year as a result of a House of Delegates resolution calling for the dissemination of information on potentially poisonous household chemicals. The Committee is studying means and recommending measures to decrease the risks of accidental poisoning. To this end, it has sponsored a conference on the health problems of household chemicals and published or prepared for publication several reports. In cooperation with the Committee on Pesticides it is presently organizing a symposium on the health hazards of chemicals for the annual meeting of the American Association for the Advancement of Science.

The Committee on Pesticides and the Committee on Toxicology are to be commended for their accomplishments and deserve continued support in their activities. They and other organizations similarly engaged in the prevention of poisoning and other accidents need the active assistance of all physicians if further gains are to be made.

FARM/CITY WEEK

In his State of the Union Message in 1954 President Eisenhower said, "The well-being of our 160 million people demands a stable and prosperous agriculture. Conversely, every farmer knows he cannot prosper unless all America prospers." Acknowledging this counsel, the American Medical Association, together with 400 other organizations, is participating this week in the first observance of Farm/City Week, October 23-29. Under the sponsorship of the Farm-City Conference, an informal alliance of leaders in industry, agriculture, and the professions, the observance is dedicated to the creation of better understanding between rural and urban dwellers. Specifically, its function is to provide demonstrations of the civic, social, and economic bonds between city and farm neighbors that characterize our national vigor.

Kiwanis International and its member clubs are spearheading this program, which is being formally launched today (October 22) by the Secretary of Agriculture Ezra Taft Benson at the Department's Agricultural Research Center in Beltsville, Md. The presence of both Secretary of Labor Mitchell and Secretary of Commerce Weeks is expected to give added momentum to the observances that are to be held throughout the United States during the ensuing days of this first Farm/City Week.

Kiwanis clubs have been requested to seek the support and manpower of medical societies in formulating and effecting these community programs. Farm/City Week is, of course, a nonpartisan public service venture, and it presents an unexcelled opportunity for medical societies to exercise civic leadership, dramatize medicine's services, win support of community health programs, and enjoy the reciprocal benefits of a cooperative public relations program.

Medicine's year-round programs covering nutrition, sanitation, physician-procurement, preventive medicine, child welfare, mental health, vocational guidance, and budgeting for medical expenses are but a few topics that are pertinent to the medical society's participation in Farm/City Week. Newspapers, radio, and television are among the communication mediums eager to receive information and to report these activities that are conducted in the interest of public health. Tours of medical facilities by civic groups and students, addresses, and open houses are also effective means of calling attention to the services of the local medical society. Because organized medicine is a recognized integrant of both rural and urban communities, doctors are urged to participate in Farm/City Week observance and thereby indicate medicine's interest in the welfare of all.

ORGANIZATION SECTION

FEDERAL MEDICAL LEGISLATION

First Session, 84th Congress

Surplus Property for Civil Defense

Senator Humphrey (D., Minn.), in S.1527, and Congressman Brooks (D., Texas), in H. R. 7227, would authorize the distribution of federal surplus property for civil defense purposes. These bills were referred to the respective government operations committees.

Educational Expenses for Higher Education

Congressman Jackson (R., Calif.), in H. R. 4444, would amend the Internal Revenue Code to provide a partial tax credit for income tax purposes for payments to educational institutions for the cost of education above the 12th grade. Credit would be given for 30% of payments, with a maximum credit of $450 for the education of each person. This measure was referred to the Ways and Means Committee.

Medical Deductions for Income Tax Purposes

Congressman Hyde (R., Md.), in H. R. 5336, would remove the 3% limitation on deductions for income tax purposes on the amounts paid for medical and dental expenses and would remove the maximum limitation on allowable medical expenses. Where the taxpayer or spouse is 65 years of age or older, the 1% limitation for drugs and medicine before deductions are calculated would also be removed. This measure was referred to the Ways and Means Committee.

Twenty Year Permanent and Total Disability

Congressman Wilson (R., Ind.), in H. R. 6447, would amend the veterans regulations to liberalize the statute used by the Veterans Administration in calculating the 20 year period following which disability rating may not be reduced. The bill would also restore disability rating that has been reduced under the present regulations, except when it could be shown that such a rating was based on fraud. Congressman Wilson proposes that the date the disability began as certified by the Veterans Administration be used instead of the actual date the determination was made, as is the present practice. This bill was referred to the Veterans' Affairs Committee.

Free Poliomyelitis Vaccine

Congressman Burnside (D., W. Va.), in H. R. 6973, provides an unlimited appropriation for poliomyelitis vaccination and would include free transportation in the event mass inoculation would take place after the close of school. This measure was referred to the Interstate and Foreign Commerce Committee. Congressman Sullivan (D., Mo.), in H. R. 7206, would authorize unlimited appropriations to permit the National Foundation for Infantile Paralysis to conduct vaccination against poliomyelitis of children under 20 years of age without any means test. The foundation would be given authority to make regulations for use of the vaccine, including allocation, distribution, and establishment of priorities. This bill was referred to the Committee on Interstate and Foreign Commerce.

Medical Advisory Committee on Alcoholism

Congressman Huddleston (D., Ala.), in H. R. 7254, would establish a medical advisory committee on alcoholism in the Department of Health, Education, and Welfare: "(1) to advise and cooperate with the United States Public Health Service (and particularly with its Mental Hygiene Division) in promoting education on alcoholism throughout the departments and agencies of the Federal Government; (2) to promote education on alcoholism throughout the several States, acting primarily through the State departments of health; (3) to advise on the establishment of clinics for the care of alcoholics; (4) to advise the departments and agencies of the Federal Government on the establishment of facilities for the care of alcoholics at various stages of the disease, and particularly to advise with respect to the different types of medical approach which are required for rehabilitation at the different stages; (5) to advise educational bodies on medical matters connected with alcoholism, and to provide for material for inclusion in the syllabus of the various educational institutions; and (6) to provide advice, from a medical, educational, community, and socio-logical point of view, regarding the care, treatment, and prevention of alcoholism throughout the country." Two-thirds of the members of the committee must be physicians licensed to practice medicine. This measure is identical with H. R. 3937 by Radwan (R., N. Y.). It was referred to the Committee on Interstate and Foreign Commerce.

Cash Disability Payments under Social Security

A series of bills were introduced to lower the age for cash disability benefit payments to those under social security who have been disabled at an earlier date than the age 65 set for those retired under the Old-Age and Survivors Insurance program. The proposals in these bills would make payments available at an earlier age, generally after six months of disability. There are minor differences in these bills: S. 2387 (Humphrey; D., Minn.), H. R. 6655 (Reuss; D., Wis.), H. R. 6580 (Karsten; D., Mo.), H. R. 6812 (Johnson; R., Wis.), H. R. 6935 (Alexander; D., N. C.), H. R. 6920 (Jennings; D., Va.), H. R. 6902 (Dorn; R., N. Y.), S.1639 (Long; D., La.), S.2293 (Kennedy; D., Mass.), H. R. 3610 (Roberts; D., Ala.), H. R. 4489 (Siler; R., Ky.), H. R. 6415 (Perkins; D., Ky.), H. R. 6898 (Canfield; R., N. J.), H. R. 7208 (Fino; R., N. Y.), and H. R. 7246 (Ashmore; D., S. C.). A number of these bills are identical with measures previously introduced. The Senate bills were referred to the Finance Committee and the House measures to the Ways and Means Committee.

From the Washington Office of the American Medical Association.

NEW DAYTIME TELEVISION PROGRAM

The American Medical Association is cooperating with a filmed television program on infant care that started the week of Oct. 16 on local stations throughout the country. Titled "It's Baby Time," the daytime program will feature W. W. Bauer, M.D., Director of the A. M. A.'s Bureau of Health Education, as medical narrator and Jane Warren, R.N., as demonstrator of nursing procedures. The 15-minute feature will take up common problems in the development and feeding of healthy babies. Since it is being placed on individual television stations and not through an established network, "It's Baby Time" will be seen on a schedule that varies from community to community. Sponsor of the show is Libby Baby Foods.

Here is the station line-up for the new program: New York, WABC, Tuesday and Thursday, 11:45 a. m.; Chicago, WGN-TV, Wednesday and Friday, 1 p. m.; St. Louis, KSD-TV, Tuesday and Thursday, 8:30 a. m.; Pittsburgh, KDKA-TV, Tuesday and Thursday, 2 p. m.; Nashville, Tenn., WSM-TV, Thursday and Friday, 12:15 p. m.; Milwaukee, WISN-TV, Thursday and Friday, 1 p. m.; Minneapolis-St. Paul, KSTP-TV, Tuesday and Thursday, 11:45 a. m.; Norfolk, Va., WTAR-TV, Thursday, 1 p. m.; Tampa-St. Petersburg, Fla., WFLA-TV, Thursday, 2:15 p. m.; Kansas City, Mo., KCMO-TV, Tuesday, 12 noon; El Paso, Texas, KROD-TV, Thursday, 11 a. m.; Louisville, Ky., WHAS-TV, Thursday, 12 noon; Mobile, Ala., WKRG-TV, Friday, 12:45 p. m.; Seattle, KING-TV, Thursday, 12:30 p. m.; and Miami, WTVJ, Monday, 9:45 a. m.

PLANS FOR RURAL HEALTH CONFERENCE

The A. M. A. Council on Rural Health met Sept. 9-10 with its advisory committee composed of representatives of leading agricultural organizations. The joint group reviewed policies and made plans for the ensuing year's activities. The advisory committee also assisted the Council in planning for the 11th National Conference on Rural Health that is to be held at the Multnomah Hotel, Portland, Ore., March 8-10. The theme will be "Your Doctor and You." The Thursday morning session, March 8, will be devoted to an informal session to study and discuss doctors' participation in community activities. The conference will take up such subjects as the family and the physician, mental health, problems of the aging, health insurance, and other health topics of interest to rural groups.

REVISED LIST OF FILMS

A revised list of films available through the A. M. A. motion picture library has been prepared, and copies are available on request from the Committee on Motion Pictures and Medical Television of the American Medical Association. This catalogue lists 83 medical films suitable for showing to medical societies, hospital staff meetings, and other scientific groups. The catalogue also includes 36 health films of interest to physicians who may be called upon to speak before lay audiences such as service organizations and Parent-Teacher Associations.

COUNCIL ON MEDICAL SERVICE

A STUDY OF MATERNAL AND CHILD CARE IN THE UNITED STATES

This is section B of the third in a series of articles by the Committee on Maternal and Child Care of the Council on Medical Service reviewing state and local medical care programs for mothers and children. Section A, on Nebraska as a whole, appeared in The Journal, *June 25, 1955, page 691. This section is devoted to maternal and child health in the communities of Lincoln and Omaha.*

Over 26% of the people of Nebraska live in the two cities of Lincoln and Omaha, 28% of the resident births in Nebraska are in these two cities, and 35% of the total births in Nebraska occur in their hospitals. It is of interest in this study, then, to examine rather closely statistics and descriptive data relative to maternal and child health in both cities with a view to correlating them with statewide statistics and factors within the metropolitan and rural areas that may have a part in the total improvement of maternal and child health in Nebraska.

Table 1.—*1953 Hospital Statistics for Lincoln*

Births		
Total infants delivered in the 3 hospitals of Lincoln		2,974
No. of stillbirths (fetal deaths reported over 20 weeks' gestation)	39 (1.3%)	
Total live births		2,935
Total live-born premature infants	135 (4.6%)	
Deaths		
Total maternal deaths		0
Total neonatal deaths		56 (19.0/1,000 live births)
Neonatal deaths due to or associated with prematurity	40 (71.4%)	
Neonatal deaths—other causes	16 (28.6%)	

MATERNAL AND CHILD HEALTH IN LINCOLN

Statistics.—According to statistics supplied by the Lincoln-Lancaster County Health Department, the city of Lincoln, with a population of 98,884 (1950 census), had 2,504 resident births in 1952 including 46 registered fetal deaths (stillbirths). Two maternal deaths occurred in 1952. Resident infant deaths in Lincoln totaled 48 (19.5 per 1,000 live births) in 1952. This represents an infant mortality rate of 17% less than the state as a whole and 32% less than the United States average. In 1953 two of the three hospitals of Lincoln had records of 237 previable fetal deaths (under 500 gm. or less than 20 weeks' gestation). These early fetal deaths are not reported as stillbirths, in accord with the state health department's definition of a stillbirth, and, therefore, many hospitals do not keep complete records. The combined rate of such early fetal deaths (abortions or miscarriages) for the two hospitals is 99.2 per 1,000 live births (exclusive of regularly reported stillbirths—so-called viable sized fetal deaths).

Committee Members are: W. L. Crawford, M.D., chairman, Rockford, Ill.; R. B. Chrisman Jr., M.D., Miami, Fla.; Philip S. Barba, M.D., Philadelphia; Harold S. Morgan, M.D., Lincoln, Neb.; J. L. Reichert, M.D., Chicago; Garland D. Murphy, M.D., El Dorado, Ark.; Howard A. Nelson, M.D., Greenwood, Miss.; and Donald A. Dukelow, M.D., consultant, Chicago.

TABLE 2.—*Age at Death in Hospital of Infants Born in Lincoln Hospitals Who Died in the Neonatal Period, by Birth Weight (1953)*

	No. of Neonatal Deaths by Completed Days of Age at Death					
Birth Weight, Gm.	Total	Under 1 Day (Under 24 Hr.)	1 Day (24-47 Hr.)	2 to 6 Days (48-167 Hr.)	7 to Under 28 Days	Age Unknown
500 or less	2	2	..	..	..	..
501-1,000	9	9	..	..	..	..
1,001-1,500	9	5	1	3	..	..
1,501-2,000	13	7	1	5	..	..
2,001-2,500	2	..	1	1	..	..
Premature, but weight unknown	5	..	..	..	..	5
Total, 2,500 or less	40	23	3	9	..	5
2,501-3,000	5	1	2	2	..	..
3,001-3,500	8	3	..	4	1	..
3,501-4,000	1	..	..	1	..	..
4,001-4,500	2	1	..	..	1	..
4,501-5,000	..	..	..	..	..	..
5,001 or more	..	..	..	..	..	..
Birth weight unknown	..	..	..	..	..	..
Total, 2,501 or more	16	5	2	7	2	..
Total	56	28	5	16	2	5

TABLE 3.—*Cause of Death in Hospital of Infants Born in Lincoln Hospitals Who Died in the Neonatal Period, by Birth Weight (1953)*

	No. of Neonatal Deaths of Live-Born Infants								
Cause of Neonatal Death *	Total	Total 2,500 Gm. or Less	500 Gm. or Less	501-1,000 Gm.	1,001-1,500 Gm.	1,501-2,000 Gm.	2,001-2,500 Gm.	Premature, but Birth Weight Unknown	Total 2,501 Gm. or More
Postnatal asphyxia and atelectasis (762)	14	7	..	..	3 (1 †)	3 (1 †)	1	..	7 (1 †)
Injury at birth (760-761)	1	..	..	..	..	..	..	..	1

All other neonatal deaths from unknown cause	..	..	..	..	..	..	..	..	..
Total	56	40	2	9	9	13	2	5	16

---

* According to International Statistical Classification of Diseases, Injuries and Causes of Death, Sixth Revision.
† Autopsy not performed in these cases.

Tables 2 and 3 indicate neonatal deaths by age and birth weight and by cause of death and birth weight respectively. The tables are given as recommended (slightly modified) in Standards and Recommendations for Hospital Care of Newborn Infants: Full Term and Premature, American Academy of Pediatrics. Of the 16 neonatal deaths unassociated with prematurity, the largest number, 7, were due to atelectasis or atelectasis combined with pneumonitis; fetal erythroblastosis caused 3 deaths and congenital heart abnormalities 3 deaths. Table 2 shows that 50% of the total neonatal deaths occurred within 24 hours after birth, and this occurrence is considerably greater for those infants whose birth weights were less than 2,500 gm. than for those over 2,500 gm. Table 3 indicates that 28 (50%) of the total neonatal deaths were classified as due to "prematurity (immaturity), unqualified" (autopsies were done on two infants in this group). The greatest specific cause of death of both premature and full-term babies was postnatal asphyxia and atelectasis, with congenital malformations the second greatest cause. Autopsies had been done in most of these cases.

Lancaster County Medical Society.—The Lancaster County Medical Society represents about 200 physicians in the city of Lincoln and county of Lancaster. Eight pediatricians and nine obstetricians serve Lincoln and environs. Although the society has regular standing committees and special advisory committees that maintain close liaison with the public, it has no special standing committee concerned with maternal and child care. The state medical association committees serve this need. The state association office is located in Lincoln.

Well-Child Conferences.—The Lincoln-Lancaster County Health Department operates two well-child clinics per week. Eligibility rules are flexible, but the clinics are maintained essentially for those who cannot afford private care. A local pediatrician is employed on a part-time basis to conduct the clinics, and attendance is arranged by appointment as scheduled by the public health nurse. Records indicate that 185 infants and preschool children made 606 visits to the clinics in 1953. In addition, 1,548 public health nursing visits were made to these and other infants and children in their homes.

Other Health Department Maternal and Child Health Activities.—A dental clinic is conducted four hours per day, five days a week, by the city-county health department under the supervision of a part-time dentist. Services are primarily for those preschool and school children who cannot afford private care. A total of 1,329 examination and treatment services were provided to 493 patients in 1953, 308 of whom were school and preschool children. The immunization service of the health department accounted for 14,835 smallpox vaccinations, plus 588 triple antigen shots and 520 booster shots given to infants and preschool and school children. The health department's maternity service (prenatal and postpartum care) was very small, with only eight patients and a total of 49 prenatal and 9 postpartum care clinic visits. The health department nurses, however, made a total of 265 field visits for antepartum and postpartum care. Expectant parent's classes are conducted each year under the auspices of the department's nursing service, the obstetric departments of the three hospitals, the medical society, the Red Cross, the local Y.W.C.A., and the state health department. Class attendance in 1953 was 582.

Child Guidance Center.—The Lincoln-Lancaster County Child Guidance Center is a nonprofit (dues-paying members) organization administered by a board of directors of 24 in cooperation with the mental health division of the state board of health (federal funds) and with additional financial assistance from the Community Chest and other agencies. Seven local physicians are members of the board of directors and five are members of the center's advisory and policy committee. The center proceeds under psychiatric guidance in all cases and is the only private resource of its kind in the state. The fee schedule is flexible, and no charge is made in appropriate cases. During 1954 approximately four diagnostic cases, two consultation cases, and four treatment cases were opened each month. Continuing treatment cases carried averaged about 35. In addition, a monthly average of 11 community presentations was made by the staff of the center.

School Health Services.—The health activities of the 31 public schools of Lincoln with an enrollment of approximately 17,000 are the direct responsibility of the board of education. The school health service staff consists of one school nursing supervisor, 13 nurses, 2 part-time dentists, an orthopedic consultant, and a psychiatric consultant. Aid comes from the local health department and the Lancaster County Tuberculosis Association in special activities such as screening for tuberculosis. The city parochial schools and county schools are provided health services by the health department. All kindergarten, third, sixth, and ninth grade public school children (approximately 3,000) are urged, through their parents, to have a physical examination by their private physician. The board of education no longer provides such examinations in the schools. Teachers and other new employees must have had complete medical examinations prior to their being accepted into the Lincoln schools. All public school children from kindergarten to the 12th grade are screened each year for nutritional status and are given vision and throat screening; audiometric tests are given to all 4th, 7th, and 10th grade students; limited dental inspections are made on all children during the first month of school; patch tests are given to all 5th grade pupils; and complete chest x-rays are done annually on all 10th grade pupils, teachers, and school employees. Health education is taught through junior and senior high school courses in health and safety and hygiene and physiology. A three hour college credit symposium in health education is offered for all teachers and nurses. Monthly meetings on health education and information on health activities in school are held for parents.

TABLE 4.—*Vital Statistics* (1952)*

Total resident births		7,079
Live births	6,959	
Registered fetal deaths (stillbirths)	120 (1.7%)	
Percentage delivered in hospitals	99.6%	
Maternal deaths (resident)	6 (0.86/1,000 live births)	
Infant deaths (resident)	176 (25.3/1,000 live births)	

---

* Omaha-Douglas County Health Department.

During the 1953-1954 school year, 2,174 pupils received school physical examinations (a new policy of not providing medical examinations in school began with the 1954-1955 school year); 22% were referred to their family physicians for follow-up and treatment. Dental inspections resulted in 16,508 referrals; vision screening resulted in 236 vision defects corrected; tuberculosis testing and x-rays resulted in 4.3% abnormal conditions found; and follow-up showed 25 pathological conditions discovered.

TABLE 5.—*1953 Hospital Statistics* for Omaha*

Births		
Total infants delivered in the 10 hospitals		9,347
No. of stillbirths (fetal deaths over 20 weeks' gestation)	124 (1.3%)	
Total live births in the 9 hospitals		9,223
Total live-born premature infants	467 (5.1%)	
Deaths		
Total maternal deaths		7 (0.76/1,000 live births)
Total neonatal deaths		158 (17.1/1,000 live births)
Neonatal deaths due to or associated with prematurity	123 (78%)	
Neonatal deaths—other causes	35 (22%)

* All hospitals of Omaha, including the U. S. Air Force Hospital at Offutt Field (outside the city limits).

MATERNAL AND CHILD HEALTH IN OMAHA

Statistics.—Omaha's 1950 census indicates 251,119 inhabitants, 25,474 (10.1%) of whom were under 5 years of age. Foreign-born white persons account for 7% and nonwhite persons another 7% of the city's population. The median school years completed for residents over 25 years of age was 11.4. Some vital statistics for 1952 relative to maternal and child health in Omaha are found in table 4. As in the previous section on Lincoln. Three additional tables are presented to give detailed information on maternal and neonatal deaths occurring in the local hospitals in 1953. These data cannot be compared with health department data in table 4 because they necessarily include other than Omaha resident births. Two of the 10 Omaha hospitals had available data on deaths (abortions or miscarriages) in previable fetuses under 500 gm. or under 20 weeks' gestation. The combined rate for these two hospitals was 54 per 1,000 live births. Table 5 summarizes the vital statistics from the 10 Omaha hospitals, and tables 6 and

TABLE 6.—*Age at Death in Hospital of Infants Born in the Ten Omaha Hospitals Who Died in the Neonatal Period, by Birth Weight (1953)*

		No. of Neonatal Deaths by Completed Days of Age at Death				
Birth Weight, Gm.	Total	Under 1 Day (Under 24 Hr.)	1 Day (24-47 Hr.)	2 to 6 Days (48-167 Hr.)	7 to Under 28 Days	Age Unknown

Total	158	67	49	30	3	9

7 give detailed information on the neonatal deaths by age at death and birth weight and by birth weight and causes of death respectively.

Almost one-half (45%) of the neonatal deaths of premature babies in Omaha hospitals occurred within 24 hours after birth, and, as with Lincoln, the number of deaths of full-term babies was only one-third as great during the first 24 hours as after that time. Autopsies had been done in one-third of the neonatal death cases that were classified prematurity, unqualified, and the total in this classification constituted over one-half (56%) of all neonatal deaths of infants under 2,501 gm. Again, as in Lincoln, the greatest specific cause (other than prematurity, unqualified) of neonatal death was postnatal asphyxia and atelectasis, with autopsy having been done in 38 out of the 43 cases in which this diagnosis was made. Congenital malformations and injuries at birth ranked second and third respectively.

TABLE 7.—*Cause of Death in Hospital of Infants Born in the Ten Omaha Hospitals Who Died in the Neonatal Period, by Birth Weight (1953)*

		No. of Neonatal Deaths of Live-Born Infants							
Cause of Neonatal Death *	Total	Total 2,500 Gm. or Less	500 Gm. or Less	501-1,000 Gm.	1,001-1,500 Gm.	1,501-2,000 Gm.	2,001-2,500 Gm.	Premature, but Birth Weight Unknown	Total 2,500 Gm. or More

* According to International Statistical Classification of Diseases, Injuries and Causes of Death, Sixth Revision.
† Autopsy not performed in these cases.

Omaha-Douglas County Medical Society.—The Omaha-Douglas County Medical Society's office, and headquarters, in Omaha is the focal point through which the profession's organized efforts reach the public. Efforts toward improvement in public health are well exemplified by the work of its committee on education and preventive medicine that, in cooperation with other agencies, keeps before the public all types of health education material from "First Aid in the Home" to "Old Wives Tales—Pregnancy" via television, radio, the press, and various publications. The society has approximately 400 active members, including 18 pediatricians and 19 obstetricians who serve the Omaha area.

Well-Child Clinics.—Eight well-child clinics covering the various areas of the city are sponsored by the Omaha-Douglas County Health Department's division of public health nursing (Visiting Nurse Association) with the cooperation of the University of Nebraska Hospital and financial support from the Community Chest and other agencies. Eligibility is limited to those under a certain income level who would otherwise probably not seek this care through a private physician. The purpose of this program is to keep the well child well and find defects early. No immunizations or treatments are given at these clinics—rather those in need of these services are referred to a private physician or the Health Department Immunization Clinic. Medical policy is determined by a medical advisory committee of the local medical society, which body also approves the physicians who conduct each clinic. During 1953 a total of 197 well-child clinics were held, serving 594 infants and 1,430 preschool children. In addition to the above-described clinics, both medical schools in Omaha have well-child clinics at their respective dispensaries that are limited to those infants delivered at their respective affiliated hospitals.

Immunization Program.—The health department and its division of public health nursing (Visiting Nurse Association) sponsor the program of immunization as a preventive health service without restriction as to income level. However, the children served are mostly those referred by public health and public school nurses. Each of the three clinics (located in strategic areas of the city) is open every Saturday morning and staffed by a part-time physician and one or more public health nurses. Children are immunized against smallpox, diphtheria, whooping cough, and tetanus; during 1953 approximately 5,000 visits were made to these clinics.

Public Health Nursing in Omaha (Relative to Maternal and Child Health).—The Visiting Nurse Association of Omaha has been incorporated into the reorganized Omaha-Douglas County Health Department as its division of public health nursing. In addition to the division's part in the above-described clinics it plays an integral part in the health services to the 41 parochial schools of Omaha and the 52 public schools in Douglas County (exclusive of Omaha). Also, the division's nursing service is available to prenatal patients on a fee basis or free, as the financial situation of the family indicates. Creighton University Dispensary routinely refers all prenatal patients to the Visiting Nurse Association. The University of Nebraska Dispensary refers many of its prenatal patients and all of its primiparas after delivery. The division nurses made a total of 33,462 home visits during 1953, and 17,739 (53%) were concerned with maternity, infant, preschool and school children, and orthopedic cases. Besides the director, the division (Visiting Nurse Association) employs an educational director, 3 supervisors, 3 physical therapists, and 27 nurses.

Health Education in Omaha (Relative to Maternal and Child Health).—The health education division of the health department directs the collection and dissemination of information relating to maternal and child health. The division assists and cooperates with other professional groups and agencies such as the medical society, dental society, P.T.A., and United Community Services. A library of books, current literature, and films is maintained; preservice programs are conducted for nurses and medical students in which the University of Nebraska, Creighton University, and the University of South Dakota participate.

Omaha Public School Dental Clinic.—The Omaha Public School Dental Clinic was established under the joint sponsorship of the Omaha Board of Education and the health department upon the recommendation of the Omaha District Dental Society after a survey in which it was concluded that dental decay was a major problem in Omaha school children and that all available preventive measures should be employed. A complete four-chair full-time dental clinic was established at Central High School. A full-time dental assistant and a receptionist are paid by the board of education. Four part-time dentists are paid by the health department (state and federal funds). During the 1952-1953 school year, 5,449 patients visited the clinic and received a total of 24,837 services, such as fillings, extractions, prophylaxis, and x-rays.

School Health Program.—The board of education through its office of special services administers the public school health program with the advice and cooperation of the health department and the local physicians. No medical director or part-time physicians are employed, and, therefore, no physical examinations are performed in the schools. Rather, this phase of the health appraisal is accomplished in private doctors' offices and at the available dispensaries and clinics for those who cannot afford private physician care. Parents are encouraged to have their children examined before kindergarten and in the 3rd, 5th, 8th, and 11th grades. The screening phase of the health appraisal of public school children is accomplished by 20 full-time school nurses and the teachers. This screening includes nutritional status, vision, hearing, skin and scalp, nervous symptoms, speech, and posture. Dental screening and examination is done by private dentists and the public school dental clinic. Tuberculin tests are given all ninth graders, cafeteria workers, teachers, and custodial help by the tuberculosis association. Teachers are oriented into the school health program during the week prior to school, and parents are kept informed on school health activities through P.T.A. and home visits by nurses. The board of education conducts a special school for the handicapped where teaching is combined with physical, occupational, and speech therapy. During the 1952-1953 school year, over 5,000 treatments were given to registered handicapped children through the public school system.

Of the 24,437 kindergarten through eighth grade pupils registered in 1952-1953, 97.4% had had a medical examination as of June 1, 1953, 7,115 (29.1%) having had one during the year, with 6,165 (87%) having been performed by the family physician. During this same year, 7,700 pupils received dental certificates for work completed or no work needed, and 3,349 additional pupils made one or more visits to a dentist; 11,324 pupils were given vision tests, resulting in 1,313 being fitted with glasses; and 2,324 had audiometric tests, with 319 defective hearing cases found and 271 pupils receiving ear examinations. During the 1952-1953 year, the total defects found through physical examinations and screening procedures were 20,187; 16,031 were seen by doctors; 14,003 corrections were made and 2,028 were under treatment; and 91.2% of the pupils had been vaccinated and 95% immunized against diphtheria and whooping cough.

CONCLUSIONS

Section B of this study, on Lincoln and Omaha, is closely related to section A, which was concerned with maternal and child care on a statewide basis. The services and facilities available and the various factors related to the improvement of maternal and child care on a state level apply with even greater emphasis to these two metropolitan areas. For instance, the median school years completed for residents of Omaha over 25 years of age was 11.4, compared to 10.1 for the state. The study (sections A and B) indicates that much emphasis has been placed on health education. The "Nebraska School-Community Health Program," the Omaha-Douglas County Medical Society's radio and television programs, the state and local health department programs, the state medical society's efforts through committees and individual members, the Nebraska Public Health Association's contributions, and the assistance from other health agencies have undoubtedly contributed to the improvement of maternal and child health.

The total neonatal death rates for the state as a whole compare very favorably with those of the hospitals of Lincoln and Omaha. Therefore, it is apparent that quality care is being administered throughout the state and that, through the emphasis on education, the citizens have been taught to seek those health services that are available to them through their private physicians. A careful study of the tables presented relative to age, weight, and cause of death should indicate quite clearly specific areas where problems still exist. The beginning that Nebraska has already made is a pointer in the direction of still greater progress in the improvement of maternal, infant, and child health in the state's metropolitan and rural areas.

The education of the laity in matters of health is important, but of equal importance is the emphasis placed upon a high standard of obstetric and pediatric care by the physicians of Nebraska. This has been greatly facilitated by the presence in Nebraska of two medical schools and their affiliated hospitals. Other hospitals of the state have tended to keep pace, due to the medical staff's awareness of facilities necessary and the state health department's assistance in maintaining high standards of hospital care for mothers and babies of Nebraska through its division of maternal and child health.

MEDICAL NEWS

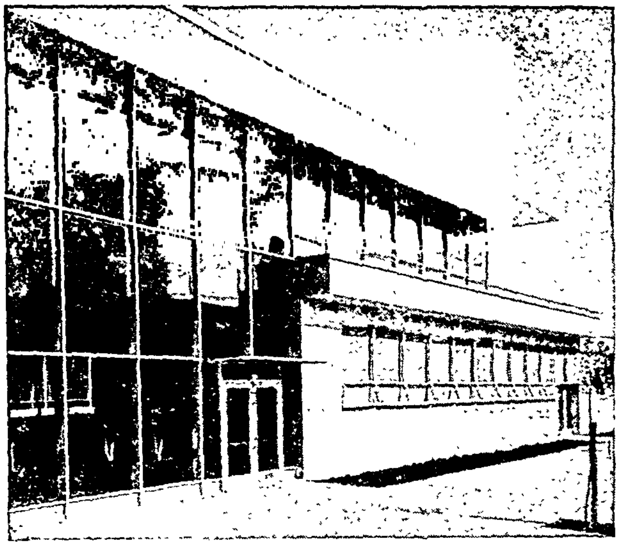
CALIFORNIA

Symposiums in San Diego.—The Los Angeles campus of the University of California School of Medicine and Medical Extension in cooperation with the San Diego County Medical Society will present the following symposiums from 2 to 10 p. m. at San Diego County General Hospital:

Oct. 26, Repair of Superficial Wounds and Burns.
Nov. 2, Radioisotopes in Medical Practice.
Nov. 9, Surgery of the Hand.

Applications should be made to Dr. Thomas H. Sternberg, Assistant Dean for Postgraduate Medical Education, University of California School of Medicine, Los Angeles 24.

Society Moves Its Headquarters.—The San Francisco Medical Society and its blood bank recently have moved from the old mansion at 2180 Washington St. to a new fireproof concrete building at 250 Masonic Ave., practically the geographical center of the city. The building may be easily expanded to a full three stories, and a balcony seating 250 may be added to the auditorium, which now seats 500. Space for the minifilm unit, an office for the woman's auxiliary, and a large kitchen adjacent to the auditorium are also on the first floor. The L-shaped blood bank, occupying the major part of the first floor, has a separate entrance. A conveyor along the south side runs from the donors' room to the refrigerator. The society entrance has a striking cantilever staircase, set in a planting area, leading to the society's administrative offices and a directors' room on the second floor. The wings of the building enclose a courtyard with a glassed-in promenade off the auditorium. Ample parking facilities are included.



Entrance to new headquarters of San Francisco Medical Society.

Course in Pediatrics.—Recent advances in basic aspects of pediatric medicine will be presented by the University of California School of Medicine and University Extension at the university's medical center in Los Angeles Oct. 27-29. The subjects include Problems in the Management of the Newborn Infant; Problems of the Noncompetitive Child; Pediatric Aspects of Cardiology; Anemias of Infancy and Childhood; and Fluid Balance and Electrolyte Therapy in Pediatrics. Application or request for information concerning this course should be made to Dr. Thomas H. Sternberg, Assistant Dean for Postgraduate Medical Education, University of California Medical Center, Los Angeles 24 (GRanite 8-9711).

COLORADO

Meeting of Hospital Association.—The Colorado Hospital Association will hold its 31st annual meeting at the Cosmopolitan Hotel, Denver, Oct. 25-26. The subjects for discussion will be "The Growth and Changing Role of Hospitals"; "Impact on Hospitals of New Methods of Treatment"; "The Chronically Ill and the Care of the Aged"; and "What Plans Should Hospitals Lay for Them?"

FLORIDA

Meeting of Practitioners.—The Florida Academy of General Practice will hold its sixth annual scientific assembly at the Princess Issena Hotel, Daytona Beach, Oct. 22-23. Presentations by out-of-state speakers will include:

Treatment of Reversible Uremia, Franklin H. Epstein, New Haven, Conn.
Management of Melanomas, Richard D. Brasfield, New York.
Various Types of Insulin and Their Use, Joseph T. Beardwood Jr., Philadelphia.
Congestive Heart Failure, Robert C. Batterman, New York.
Medical Complications of Pregnancy; Clinical Aspects of the Contracted Pelvis, Willis E. Brown, Little Rock, Ark.
Care of the Newborn, Thomas E. Bailey, Augusta, Ga.

The sessions will close with a clinicopathological conference by Dr. William W. Schildecker, Daytona Beach. A cocktail party, Saturday 6 p. m., will precede the annual banquet, at which the principal speaker, Dr. Frank G. Slaughter, Jacksonville, will have as his subject "Physician's Heritage."

ILLINOIS

Personal.—Dr. Harold C. Lueth, Evanston, has been promoted to the rank of brigadier general in the Army Reserve by the Illinois Military District, with headquarters in Chicago. He is currently commanding general of the 801st Medical Detachment (hospital center).

Diamond Jubilee.—The Winnebago County Medical Society celebrated its 75th anniversary on Oct. 11 at Rockford. Dr. Elmer Hess, Erie, Pa., President of the American Medical Association, appeared in a society-sponsored television program, "Let's Talk It Over," in the afternoon and in the evening addressed the members of the society and guests at the Forest Hills Country Club. Dr. Hess was the speaker at the noon meeting of the Kiwanis Club.

Chicago

Dallas B. Phemister Lecture.—Dr. Charles F. W. Illingworth, Regius Professor of Surgery, University of Glasgow, will deliver the second Dallas B. Phemister Lecture at the Billings Hospital Auditorium, 950 E. 59th St., Oct. 28, 8 p. m. The subject of his address will be recent research on peptic ulcer. The profession is invited.

Phi Beta Pi Lecture.—Theta chapter of Phi Beta Pi fraternity will sponsor its annual Stephen Walter Ranson Lecture at 4 p. m. Oct. 27 in Thorne Hall on the Northwestern University campus at Superior Street and Lake Shore Drive. Dr. John H. Lawrence, chief, Donner Laboratories, University of California, Berkeley, will discuss "Some Recent Investigations in Medicine."

Blatt Memorial Lecture.—The pediatric staff of the Cook County Hospital announces that the seventh annual Maurice Lamm Blatt Memorial Fund Lecture will be given Oct. 24, 8:30 p. m., in the Medical Amphitheater of the Cook County Hospital. Dr. Wolfgang W. Zuelzer, director of laboratories of the Children's Hospital, Detroit, will discuss "Maternal Fetal Incompatibility in the O-A-B System and Hemolytic Disease of the Newborn."

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

Wilder Memorial Lecture.—The sixth William Hamlin Wilder Memorial Lecture of the Institute of Medicine of Chicago, an illustrated presentation, "Human Toxoplasmosis with Special Reference to Intraocular Inflammation," by Dr. Albert B. Sabin, professor of research pediatrics, University of Cincinnati College of Medicine, will be delivered at a joint meeting of the institute, the Chicago Society of Internal Medicine, and the Chicago Ophthalmological Society at the Drake Hotel, 8:15 p. m., Oct. 24. All are welcome. Telephone during the meeting, SUperior 7-2200. Preceding the meeting there will be cocktails at 6 p. m. followed by dinner ($5.75 per plate).

Mayo Memorial Lectures.—Prof. Erling Dahl-Iversen, professor of surgery, University of Copenhagen, Denmark, will deliver the Charles H. Mayo Memorial Lectures at Thorne Hall (Superior Street and Lake Shore Drive), Northwestern University Medical School. Prof. Dahl-Iversen, who is also chief of surgical services of the University Surgical Clinic at Rigshospitalet, Copenhagen, will address Chicago physicians and surgeons at 4 p. m. Oct. 26 on the functions of the endocrine organs during the postoperative period. The lectureships on surgery were instituted in 1931 by the late Dr. Charles H. Mayo, founder of the Mayo Clinics, who was graduated from Northwestern University Medical School in 1888.

Meeting on Cerebral Palsy.—"Trends in Cerebral Palsy Care and Treatment" will be the theme of a meeting sponsored by the United Cerebral Palsy Association of Illinois, United Cerebral Association of Chicago, Parents Association for Cerebral Palsy Children, and the Spastic Paralysis Aid Foundation on Oct. 29, 8:30 a. m., at the Spalding School, 1628 W. Washington Blvd. Trends in medical care will be discussed by Dr. Edward F. Lis, Research and Educational Hospitals, and trends in research by Dr. Glidden L. Brooks, national medical director, United Cerebral Palsy Association, New York. A tour of Spalding School will precede luncheon and the afternoon discussion groups. Parents of cerebral palsied children and interested professional persons are cordially invited. There is no registration fee.

MARYLAND

University News.—Dr. Samuel P. Bessman, director of biochemical research of the Research Foundation at Children's Hospital, Washington, D. C., has been appointed associate professor of pediatrics in the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore.

Practitioners Meet in Baltimore.—The Maryland Academy of General Practice will hold its seventh annual scientific assembly at the Sheraton Belvedere Hotel in Baltimore Oct. 26-27. Dr. Merrill M. Cross, Silver Spring, president, will serve as toastmaster at the banquet Wednesday, 7 p. m., at which Mr. Mac F. Cahal, Kansas City, Mo., executive secretary, American Academy of General Practice, will be the speaker. Other out-of-state speakers include:

Walter A. L. Thompson, New York, Orthopedic Problems Encountered in General Practice.
Laurence L. Robbins, Boston, Roentgenology and the General Practitioner.
Elmer C. Bartels, Boston, Medical Treatment of Thyroid Disease.
Henry P. Laughlin, Washington, D. C., Psychiatry in General Practice.
George L. Kelly, Augusta, Ga., Problems of Libido and Potentia Encountered in General Practice.
Frederic D. Zeman, New York, General Therapeutic Considerations.
Murray B. Ferderber, Pittsburgh, Rehabilitation.
Austin I. Dodson, Richmond, Va., Treatment of Urinary Tract Infections.

MASSACHUSETTS

Meeting of Diabetes Association.—The New England Diabetes Association will meet Oct. 25, 8 p. m., in the Joslin Auditorium of the New England Deaconess Hospital, Boston. Herman B. Chase, Ph.D., professor of biology at Brown University, Providence, R. I., will speak on inherited insulin resistance in animals, and Dr. Russell J. Barrnett, assistant professor of anatomy at Harvard Medical School, Boston, will talk on histochemical demonstration of insulin.

MISSOURI

Ginsberg Memorial Seminar.—The first annual Dr. A. Morris Ginsberg Memorial Clinical Seminar, established in memory of the late clinical professor of medicine at the University of Kansas, will be held in the auditorium of the Menorah Medical Center, Kansas City, Oct. 27-29. Dr. Meyer Friedman, director, Brunn Cardiovascular Research Institute at Mount Zion Hospital, San Francisco, will lecture on "Functional and Cardiovascular Disease," "Studies in Digitalis Therapy," and "Cholesterol Metabolism" at 10 a. m. Thursday, Friday, and Saturday respectively. He will also lead the panel discussion on Hypertension, Thursday; Clinical Use of Digitalis, Friday; and Clinical Management of Coronary Arteriosclerosis, Saturday; each to be held at 11:30 a. m. A clinicopathological conference will take place at 2 p. m. Thursday, and a combined staff conference will be held at 9 a. m. Saturday. Daily ward rounds and informal discussions with the Menorah staff will be conducted by Dr. Friedman. Physicians in the Kansas City area are invited to participate.

NEBRASKA

Mid-West Clinical Society.—The Omaha Mid-West Clinical Society will hold its 23rd annual assembly Oct. 24-27 at the Hotel Paxton. A panel discussion on upper gastrointestinal hemorrhage is scheduled for Monday, 1:30 p. m. At the dinner, 6 p. m., Dr. Frank H. Bethell, Ann Arbor, Mich., will lead a discussion on hemorrhagic disorders. The Tuesday afternoon session will open with a panel discussion, "Treatment of Carcinoma of the Endometrium." Dr. Harold D. Palmer, Denver, will be leader for the Tuesday dinner discussion, "Malignant Lesions of the Abdomen and Pelvis in Infants and Children." The Wednesday afternoon panel discussion, 1:30 p. m., will be devoted to poisoning in children. The dinner discussion leader will be Dr. Francis L. Lederer, Chicago ("Adenoid and Tonsil Operations—To Be or Not to Be"). Panel discussion Thursday, 1:30 p. m., will be on treatment of cardiovascular problems. The dinner, 6 p. m., at which Dr. J. Scott Butterworth, New York, will lead the discussion about "Auscultation of the Heart—A Neglected Art," will be followed by an evening meeting, 7:30 p. m., at which Dr. Charles W. Mayo, Rochester, Minn., will have as his subject "The United Nations and the Role of Doctors and Medicine in International Relations."

NEW YORK

Sixth Wadsworth Lecture.—The sixth Augustus B. Wadsworth Lecture will be given at the division of laboratories and research, New York State Department of Health, Albany, Oct. 27, by Dr. John G. Kidd, professor of pathology, Cornell University Medical College, New York City, on "Immunological Approaches to the Problems of Cancer."

Personal.—The Samuel Sackett Foundation, which studies rheumatic fever and its related diseases, announces that Dr. Gene H. Stollerman, medical director of Irvington House in Irvington, has been appointed to direct rheumatic fever research in the department of medicine of Northwestern University Medical School, Chicago. The research program was made possible by the income from a $500,000 endowment providing for the research on a permanent basis.

New York City

Second Harvey Lecture.—Ernest F. Gale, director, Medical Research Council Unit for Chemical Microbiology, University of Cambridge, England, will deliver the second Harvey Lecture of the current series at the New York Academy of Medicine on Oct. 27 on "Nucleic Acids and Protein Synthesis."

Meding Award.—The Dr. Charles Bramman Meding award, granted annually to a person judged to have made an important contribution to the advancement of otolaryngology and/or ophthalmology, will be presented to Dr. Franz Altmann on Oct. 28 by the Harlem Eye and Ear Hospital. Dr. Altmann's film, "Embryology of the Ear," will be shown at the hospital auditorium coincident with the presentation of the award.

Symposium on Diabetes.—The third symposium on diabetes mellitus will be held Oct. 27 at the Memorial Center for Cancer and Allied Diseases, 410 E. 68th St., under the sponsorship of the Clinical Society of the New York Diabetes Association. The topic for discussion will be "The Pituitary-Adrenal System and Diabetes Mellitus." Out-of-state speakers include Dr. Carl F. Cori, St. Louis, Dr. Rachmiel Levine, Chicago, and Dr. E. Perry McCullagh, Cleveland. The sessions are open to physicians, medical students, and other professional personnel. Advance registration must be made through the New York Diabetes Association, 270 Park Ave., New York 17. There is no registration fee.

Assistant Medical Examiner Wanted.—The Department of Personnel, city of New York, is reopening applications for assistant medical examiner (office of the chief medical examiner). Persons who filed applications in March, 1954, are requested to bring their applications up to date. The salary range is from $8,200 to $10,300 a year, and the position offers pension, sick leave, and paid vacations. The minimum requirements are an M.D. degree from an accredited school; one year of formal appointment as intern in an approved general hospital; two years of training or full-time experience in gross and microscopic pathology in a laboratory of an approved university, morgue, or hospital, or a satisfactory equivalent; evidence, subject to official verification, of having performed 150 autopsies; and a valid New York State license to practice medicine. Applications, together with the $5 fee, will be accepted to 4 p. m., Oct. 26, at the Department of Personnel, 96 Duane St., New York 7. A request for application by mail must be accompanied by a 9 in., self-addressed envelope, stamped 6 cents for return.

NORTH CAROLINA

Annual Symposium at Raleigh.—The seventh annual medical and surgical symposium of the Raleigh Academy of Medicine will be held Oct. 27 at the Sir Walter Hotel in Raleigh, beginning at 9:30 a. m. and terminating with an after-dinner address. The following program will conclude with panel discussion by all participants:

Hypertensive Toxemias of Pregnancy, Leon C. Chesley, Ph.D., State University of New York College of Medicine, Brooklyn.
Medical Diseases Complicated by Pregnancy, Alvin J. B. Tillman, Columbia University College of Physicians and Surgeons, New York.
Vaginitis and Vulvovaginitis, C. P. Jones, M.T., consulting bacteriologist, Duke Hospital, Durham.
Vaginal Hysterectomy, Edward D. Allen, Chicago.
Developmental Picture of Carcinoma of the Cervix, Cyrus C. Erickson, University of Tennessee College of Medicine, Memphis.

Dr. Robert A. Kimbrough, Philadelphia, will moderate the program and the panel discussion and will deliver the after-dinner address, "Carcinoma of the Cervix." All physicians are cordially invited to attend the symposium, the cocktail hour, and the dinner as guests of the academy.

OHIO

Course on Gastroenterology.—The Frank E. Bunts Educational Institute, Cleveland, announces a postgraduate continuation course, "Newer Developments in Gastroenterology," Oct. 26-27, including discussions of the surgical and medical aspects of gastrointestinal diseases; demonstrations of the newer roentgenographic techniques used in diagnosis of hiatus hernia, jejunal ulcer, diverticulum, and papilla of the colon, with special attention to intravenous cholangiography; and a practical demonstration of laboratory procedures. Information may be obtained from the Secretary of the Frank E. Bunts Educational Institute, 2020 E. 93rd St., Cleveland 6.

OKLAHOMA

Personal.—The citizens of Blair and the surrounding area held an all-day celebration in tribute to Dr. Robert Z. Taylor on his 71st birthday. Dr. Taylor has been practicing in Blair since 1909.

Meeting of Clinical Society of Oklahoma City.—The 25th annual conference of the Oklahoma City Clinical Society will convene Oct. 24-27 at the Biltmore Hotel. Dr. Elmer Hess, Erie, Pa., President, American Medical Association, will deliver the banquet address Monday. Other guest lecturers are: Drs. James H. Allen and Theodore A. Watters, New Orleans; Edward P. Cawley, Charlottesville, Va.; Richard V. Ebert, Little Rock, Ark.; Keith S. Grimson, Durham, N. C.; John R. Hannan, Cleveland; Arild E. Hansen, Galveston, Texas; Carl P. Huber and Edward B. Smith, Indianapolis; Raymond J. Jackman, Rochester, Minn.; Emanuel M. Papper, New York; Homer E. Prince, Houston, Texas; Clyde L. Randall, Buffalo; Lowell A. Rantz, San Francisco; Dana M. Street, Memphis, Tenn.; and Everett D. Sugarbaker, Jefferson City, Mo. The sessions will include a clinicopathological conference, general assembly, round-table luncheons, a smoker, and dinner meetings. The registration fee of $20 includes all these features. For information address: Executive Secretary, 503 Medical Arts Bldg., Oklahoma City.

PENNSYLVANIA

Medical Examiner System.—As the final step in establishing the medical examiner system in Philadelphia, where nonmedical personnel have previously held the post of coroner, the Philadelphia Department of Public Health has announced plans to fill the position of medical examiner with a physician trained in pathology and forensic medicine. Recent legislation of the Philadelphia City Council defined the post as one responsible to the department of public health and enabled the health department itself to set the requirements for Civil Service appointment to the position.

Philadelphia

Geriatrics Conference.—The Home for the Jewish Aged, 5301 Old York Rd., will sponsor the first annual medical symposium on clinical aspects of the aging process, with special reference to neurology, psychiatry, nutrition, and cardiology, Oct. 23, 10 a. m.-4 p. m. Dr. Nathan Blumberg, medical director of the home, will serve as chairman. The following panels will be presented: (1) Neurology and Psychiatry, Drs. Matthew T. Moore and Maurice E. Linden, Philadelphia, and Abraham M. Rabiner, Brooklyn, N. Y.; (2) Nutrition, Drs. Robert S. Goodhart, New York, Donald M. Watkin, Staten Island, N. Y., and Hertha K. Sorter, Chicago; and (3) Cardiology, Drs. James B. Donaldson, Philadelphia, Raymond Harris, Albany, N. Y., and Simon Dack, New York. Luncheon will be served at 1 p. m. Physicians are cordially invited.

Pemberton Lecture on Rheumatoid Disease.—The fifth annual Dr. Ralph Pemberton Memorial Lecture, "The Nature of Rheumatoid Disease," will be delivered by Dr. Metro A. Ogryzlo, assistant professor of medicine, University of Toronto Faculty of Medicine, Toronto, Canada, under the sponsorship of the eastern Pennsylvania chapter of the Arthritis and Rheumatism Foundation and the Philadelphia Rheumatism Society Oct. 27, 8:30 p. m., at the Philadelphia County Medical Society, 301 S. 21st St. A reception and dinner (subscription $6) will be held at 6 p. m. Physicians may place reservations through Dr. William J. Somerville, Chairman, % Arthritis and Rheumatism Foundation, John Bartram Hotel, Philadelphia 7. Formal credits will be allowed for the lecture by the Academy of General Practice. The public is invited.

VERMONT

New Department of Preventive Medicine.—The University of Vermont College of Medicine, Burlington, announces the Commonwealth Fund of New York City has approved a project for the establishment of a new department of preventive medicine and for the development of a Regional Medical Needs Project. The project is to run four years, beginning Feb. 1, 1956. Dr. Leon R. Lezer, assistant professor of preventive medicine at the college, is chairman of the 16-member committee, formed to consider the rural medical needs of Maine, New Hampshire, and Vermont. The new department, consisting of a sociologist, medical social worker, public health nurse, health educator, statistician, and secretarial help, will be "the nucleus that will develop a teaching program in comprehensive medical care." It will also be a primary function of the staff to "act as consultants on request to rural areas in Maine, New Hampshire, and Vermont in studying local medical needs."

Serving on the committee with Dr. Lezer are commissioners of health, medical society officers, and members of medical college faculties from Vermont, New Hampshire, and Maine.

WEST VIRGINIA

Personal.—Dr. Ralph W. Ryan, Morgantown, has accepted appointment as civilian consultant in ophthalmology to the National Institutes of Health at Bethesda, Md., where he will do research in the control of eye diseases. He will, however, continue the practice of his specialty in Morgantown.

State Medical Election.—Dr. Athey R. Lutz, Parkersburg, was recently elected president of the West Virginia State Medical Association; Dr. E. Lyle Gage, Bluefield, first vice-president (reelected); Dr. Charles A. Hoffman, Huntington, second vice-president; and Dr. T. Maxfield Barber, Charleston, treasurer (reelected). The next annual meeting will be held at the Greenbrier Aug. 23-25, 1956.

WISCONSIN

Course on Radioisotopes.—A course for nonradiologists on the application of radioisotopes in clinical medicine is being offered on four consecutive Thursday afternoons, beginning Oct. 20, 10 a. m., at Marquette University School of Medicine, Milwaukee. The course is under the direction of Dr. Irving I. Cowan, director of the department of isotopes and assistant clinical professor of radiology. Tuition is $20 for the eight-hour course.

GENERAL

Meeting of Industrial Council.—At its annual meeting at the Rensselaer Polytechnic Institute in Troy, N. Y., Oct. 27-29, the Industrial Council, a national forum of educators and American industry, will have as its subject "The Pharmaceutical Industry." The principal speakers will include Pierre A. deTarnowsky, Mead Johnson & Company, Evansville, Ind.; Dr. Theodore G. Klumpp, Winthrop-Stearns, Inc., New York; Dr. Raymond M. Rice, Eli Lilly and Company, Indianapolis; and Ernest H. Volwiler, Ph.D., Abbott Laboratories, North Chicago, Ill.

Western Psychiatric Convention.—The first Western Divisional Meeting of the American Psychiatric Association will be held in San Francisco Oct. 27-30 as a joint meeting with the West Coast psychoanalytic societies. Papers on psychosomatic medicine, psychophysiological response to stress, use of reserpine and chlorpromazine, child psychiatry, group therapy, and teaching of psychiatry have been scheduled. Dr. William G. Barrett, San Francisco, president-elect, American Psychoanalytic Association, will give the academic lecture. The Northern California Psychiatric Society is the host society of the convention. Its newly elected officers are: Dr. Alfred Auerback, San Francisco, president; Dr. William R. Sheehy, Berkeley, vice-president; and Dr. Thomas A. Gonda, San Francisco, secretary-treasurer.

Association of Medical Colleges.—The 66th annual meeting of the Association of American Medical Colleges will be held at the New Ocean House, Swampscott, Mass., Oct. 24-26. The meeting will open Monday with the introduction of new deans. Reports on experiments in medical education will be made Monday and Tuesday afternoons. The following symposium on compensation of faculties of clinical departments will be presented Wednesday morning:

The Full-Time Plan at the University of Chicago, Lowell T. Coggeshall, Chicago.
The Private Diagnostic Clinic at Duke University, Wilburt C. Davison, Durham, N. C.
The University of Virginia Plan, Thomas H. Hunter, Charlottesville, Va.
The University of Iowa Plan, Norman B. Nelson, Iowa City.
The Harvard University Plan, George Packer Berry, Boston.

Meeting of Parenteral Drug Association.—The Parenteral Drug Association will hold its annual meeting Oct. 25-27 at the Hotel New Yorker in New York City. The sessions will open with "Changes Made in the U. S. P. XV Affecting Parenterals" by Lloyd C. Miller, Ph.D., U. S. Pharmacopeia, New York. "Physician Preference in Types of Parenteral Products" will be discussed by Dr. Herbert S. Kupperman, New York University College of Medicine, New York. Dr. Arnold J. Lehman, Food and Drug Administration, Washington, D. C., will present "Pharmacological Testing of New Parenterals." Round-table discussions have been scheduled on the U. S. P., 15th revision, sterility tests and on a program of collaborative research. Dr. Austin Smith, Editor of The Journal, guest of honor and speaker at the banquet, will discuss "Trends in Drug Evaluation."

Meeting of Gastroenterologists.—The second annual convention of the American College of Gastroenterology Oct. 24-26 at the Shoreland Hotel, Chicago, will be followed by a course in postgraduate gastroenterology Oct. 27-29. Attendance at the course will be limited to those who have paid the matriculation fee. Dr. Lynn A. Ferguson, Grand Rapids, Mich., president, will preside over the first scientific session Monday morning. Dr. Martin E. Rehfuss, Philadelphia, will be the speaker at the luncheon, 12:30 p. m. Monday (sponsored by Burton, Parsons & Company; admission by card only). Tuesday at 2 p. m. Dr. Clifford J. Barborka, Chicago, will moderate a panel discussion on peptic ulcer. Participants include Dr. H. Marvin Pollard, Ann Arbor, Mich., and Drs. Robert B. Lewis, E. Clinton Texter Jr., and Walter W. Carroll, all of Chicago. The banquet will be held at 7:30 p. m. Tuesday. More than 29 invited speakers will participate in the scientific sessions.

Anesthesiologists Meet in Boston.—The American Society of Anesthesiologists will hold its annual session at the Hotel Statler, Boston, Oct. 29-Nov. 2. The sessions will open Monday morning with panel symposiums on the endocrine factors in response to anesthesia and surgery. Other panel symposiums will include "The Effects of Anesthetics on the Circulatory Dynamics," "Hypothermic Anesthesia," "What Are the Causes of Death Relative to Anesthesia and Surgery?" and "What Influence Does the Anesthetic Agent Have on the Mortality Rate?" Monday at 8 p. m. there will be an informal meeting to discuss problems related to electroencephalography in anesthesia and to show records of the current investigations in this field. At a historical session Wednesday morning Dr. Albert M. Betcher, New York, will present "The Jubilee Year of Organized Anesthesia," and Dr. F. A. Duncan Alexander, Iowa City, will have as his topic, "James Leonard Corning and the Origins of Spinal Analgesia and Anesthesia."

Symposium on Tuberculosis in Childhood.—The National Jewish Hospital, Denver, will present a Symposium on Tuberculosis in Infancy and Childhood Nov. 9-13. No registration fee will be required. Applications will be considered in order of their receipt by the executive chairman, Dr. Gardner Middlebrook, Denver. Dr. Rene J. Dubos, New York, moderator for the opening session, will present "The Problem," which will be followed by "Historical Comments" by Dr. Bela Schick, New York, and "Morphology of Tuberculous Lesions" by Dr. Kornel L. Terplan, Buffalo. Some 24 presentations will be made, including:

Immunopathology of Tuberculosis, Sidney Raffel, Menlo Park, Calif.
Dynamics of Antituberculous Chemotherapy, Walsh McDermott, New York.
Unusual Cases of Tuberculosis, Ralph V. Platou, New Orleans.
Clinical Aspects of the Natural History of Tuberculosis in Infants and Children, Edith H. Lincoln, New York.
Correlation of in Vitro Sensitivity of M. Tuberculosis with Clinical Response of Patient to Therapy, Hattie E. Alexander, New York.
Management of Special Problems in the Chemotherapy of Tuberculosis in Infants and Children, Jose E. Sifontes, Syracuse, N. Y.

Annual Session on Surgery of Trauma.—The American Association for the Surgery of Trauma will hold its 15th annual session Oct. 27-29 at the Drake Hotel, Chicago. The closing presentation, the presidental address by Dr. Robert H. Kennedy, New York, will be preceded by a symposium (Discussion of Disability Evaluation by Members of the Disability Evaluation Committee of the American Medical Association), presented by Drs. Alexander P. Aitken, Brookline, Mass.; Alfred H. Whittaker, Detroit; Henry H. Kessler, Newark, N. J. (by invitation); and Earl D. McBride, Oklahoma City (by invitation). The program of 40 papers includes 39 invited participants. A cocktail hour at 7 p. m. Friday will precede the annual banquet (black tie preferred), at which Dr. Eric Oldberg, professor of neurology,

Symposium on Diabetes.—The third symposium on diabetes mellitus will be held Oct. 27 at the Memorial Center for Cancer and Allied Diseases, 410 E. 68th St., under the sponsorship of the Clinical Society of the New York Diabetes Association. The topic for discussion will be "The Pituitary-Adrenal System and Diabetes Mellitus." Out-of-state speakers include Dr. Carl F. Cori, St. Louis, Dr. Rachmiel Levine, Chicago, and Dr. E. Perry McCullagh, Cleveland. The sessions are open to physicians, medical students, and other professional personnel. Advance registration must be made through the New York Diabetes Association, 270 Park Ave., New York 17. There is no registration fee.

Assistant Medical Examiner Wanted.—The Department of Personnel, city of New York, is reopening applications for assistant medical examiner (office of the chief medical examiner). Persons who filed applications in March, 1954, are requested to bring their applications up to date. The salary range is from $8,200 to $10,300 a year, and the position offers pension, sick leave, and paid vacations. The program of 40 papers includes 39 invited participants. A cocktail hour at 7 p. m. Friday will precede the annual banquet (black tie preferred), at which Dr. Eric Oldberg, professor of neurology, and neurological surgery, University of Illinois College of Medicine, Chicago, will have as his topic "Inside a Symphony Orchestra." Dr. Oldberg is president of the Chicago Orchestral Association. Ladies and guests are invited to the annual dinner.

Congress of Neurological Surgeons.—The fifth annual meeting of the Congress of Neurological Surgeons will convene at the Hotel Statler, Los Angeles, Oct. 27-29. Dr. Carl W. Rand, University of Southern California School of Medicine, Los Angeles, will present "Notes on Pituitary Tumors," "Histological Changes of the Injured Brain with Clinical Applications," and "Brain Tumors Complicating Pregnancy and Spontaneous Subarachnoid Hemorrhage Occurring in Noneclamptic Pregnancy." Other guest speakers are: Dr. H. Russell Meyers, Iowa City; Dr. John E. Webster, Detroit; Dr. William H. Sweet, Boston; Dr. Cyril B. Courville, Dr. Johannes M. Nielsen, Dr. Lawrence H. Arnstein, Dr. Richard A. Koons, and Horace W. Magoun, Ph.D., Los Angeles; and Dr. Robert H. Pudenz, Dr. James G. Golseth, and Anthonie Van Harreveld, Ph.D., Pasadena, Calif. Dr. Golseth will conduct a postgraduate course on electromyography on Wednesday. Symposiums have been scheduled on neurophysiology, carotid artery thrombosis, and hypothermia and hibernation in neurosurgery. The banquet Thursday will be preceded by cocktails, 6:30 p. m. On Oct. 31 the congress will hold a joint meeting with the Sociedad Mexicana de Cirugia Neurologica in Mexico City, where a symposium will be presented on cysticercosis of the central nervous system.

Meeting of Gerontological Society.—The eighth annual meeting of the Gerontological Society will be held in the Sheraton-Belvedere Hotel, Baltimore, Oct. 27-29. Dr. Frederic D. Zeman, New York, will serve as chairman for the first general session Thursday morning, which will have as its topic "Basic Considerations—Medical and Social Problems of the Aging and the Aged." Dr. Edward L. Bortz, Philadelphia, will be chairman of the second general session, Friday morning, when the subject will be "Whither Gerontology? Current Research Needs." The section on clinical medicine will meet jointly with the Maryland Academy of General Practice Thursday afternoon to discuss "Everyday Problems in the Care of the Elderly." Friday afternoon that section will hold a joint meeting with the Commission on Chronic Illness to consider "Old Age and Chronic Illness." Thursday afternoon staff members of the National Institute of Mental Health, National Institutes of Health, Bethesda, Md., will present a symposium, "The National Institute of Mental Health and Problems of Aging," for the section on psychological and social sciences. The society will be guests of the Medical and Chirurgical Faculty of the State of Maryland and the Baltimore City Medical Society at an evening session Thursday, at which an address, "Education for Gerontology," will be delivered by Dr. Frederick C. Swartz, East Lansing, Mich.

Gulf Coast Clinical Society.—The Gulf Coast Clinical Society, composed of physicians from southern Alabama, southern Mississippi, and northwest Florida, will hold its 15th annual meeting at the San Carlos Hotel, Pensacola, Fla., Oct. 27-28. Presentations by out-of-state speakers include:

Mechanism of Action of the Antibiotic Drugs, John C. Krantz Jr., Baltimore.
Gyne-Chiatry, William K. Keller, Louisville, Ky.
Fever of Unknown Origin, Max Michael Jr., New York.
Angiocardiography, Jarrell E. Miller, Dallas, Texas.
Tumors Primary in the Neck, Grant E. Ward, Baltimore.
Mechanisms Responsible for Recurrent Bronchopulmonary Infection, Edwin R. Levine, Chicago.
New Light on the Etiology of Gastric and Duodenal Ulcer, Lester R. Dragstedt, Chicago.

At luncheon, Thursday 12:30 p. m., Drs. Ward, Levine, and Krantz will conduct a round-table discussion, "Etiology and Treatment of Bronchiogenic Carcinoma." A cocktail party, 6:30 p. m., will precede the banquet at the Pensacola Country Club (courtesy of Van Antwerp's Surgical Supply, Inc., Mobile, Ala.). The sessions will end with the presentation of a clinicopathological conference Friday, 11:20 a. m., by Drs. Michael, Dragstedt, and Miller, and Dr. W. A. D. Anderson, professor of pathology, University of Miami School of Medicine, Coral Gables, Fla.

Surgeons Meet in Chicago.—The American College of Surgeons will hold its clinical congress Oct. 31-Nov. 4 at the Conrad Hilton Hotel, Chicago. Panel discussions will be held on surgery of the thyroid, parenteral therapy, carcinoma of the breast, surgery in patients with cardiac disease, surgery and anesthesia, benign lesions of the pancreas, and surgery of the colon. The Monday afternoon session will open with a clinicopathological conference. During the general sessions, symposiums will be presented on trauma, cancer, new or unusual problems in surgery, and graduate training in surgery and the surgical specialties. The general sessions will close with a discussion "What's New in Surgery?" based on papers presented during the forum on Fundamental Surgical Problems. The 10th Martin Memorial Lecture, "Current Dilemmas of Doctors and Others," will be delivered Monday evening by Grayson L. Kirk, Ph.D., New York, president of Columbia University. The oration on trauma will be made Thursday afternoon by Dr. Frank B. Berry, Washington, D. C., assistant secretary of defense, whose subject will be "Mass Casualties." Dr. Warren H. Cole, Chicago, will be installed as president of the college on Friday evening, when he will speak on "Surgical Philosophy Old and New." During the congress, operations performed at the University of Illinois Research and Educational Hospitals will be televised in color. Questions from the audience will be relayed to, and answered by, the operating team, while the operation is in progress.

Society News.—Newly elected officers of the **American Association of Railway Surgeons** include Dr. Richard A. Sutter, St. Louis, president; Dr. Harold A. Spilman, Ottumwa, Iowa, president-elect; Drs. Joseph F. Prinzing, Denver, Ernest Colli, New Orleans, and Lloyd A. Hamilton, Lambertville, N. J., vice-presidents; Dr. Theodore L. Hansen, Chicago, treasurer; Dr. Chester C. Guy, Chicago, secretary; Dr. James K. Stack, Chicago, recorder; and Mr. H. S. Dewhurst, Chicago, assistant secretary-treasurer.——Officers of the newly organized **Society for Research on the Reticuloendothelial System** include: Dr. Charles A. Doan, Columbus, Ohio, president; Dr. Leon O. Jacobson, Chicago, vice-president; and Dr. John H. Heller, Ridgefield, Conn., executive secretary. Members of the group are specialists in internal medicine, microbiology, endocrinology, immunology, nutrition, and radiology. The membership represents more than 100 institutions of learning and hospitals in the United States, Europe, South America, and the Middle East. Its national headquarters are in Ridgefield, Conn.——The **American Board of Clinical Chemistry, Inc.,** which held its annual meeting at Henry Ford Hospital, Detroit, May 20-21, announces that a complete Directory of Certified Clinical Chemists, obtainable from the secretary-treasurer, Dr. Oliver H. Gaebler, Henry Ford Hospital, Detroit 2, will be sent without charge to hospital departments or other laboratories that engage in clinical chemistry.——William H. Feldman, D.V.M., Rochester, Minn., has been elected chairman of the advisory medical board of the **Leonard Wood Memorial (American Leprosy Foundation),** succeeding Dr. Howard T. Karsner, Washington, D. C., who has been made a special consultant to the board. Other new members of the board are Dr. Fred L. Soper, Washington, D. C., director, Pan American Sanitary Bureau; Dr. Thomas B. Turner, Baltimore; and Dr. Thomas H. Weller, Boston.——Newly elected officers of the **American College of Chest Physicians** include: Dr. James H. Stygall, Indianapolis, president; Dr. Herman J. Moersch, Rochester, Minn., president-elect; Dr. Burgess L. Gordon, Philadelphia, first vice-president; Dr. Donald R. McKay, Buffalo, second vice-president; Dr. Charles K. Petter, Waukegan, Ill., treasurer; and Dr. Albert H. Andrews, Chicago, assistant treasurer. The next annual meeting will be held at the Sherman Hotel, Chicago, June 7-10, 1956. ——At the annual meeting of the **Aero Medical Association** Dr. Kenneth E. Dowd, Montreal, Canada, was elected president; Dr. Jan H. Tillisch, Rochester, Minn., president-elect; Capt. Ashton Graybiel (MC), U. S. N., Pensacola, Fla., first vice-president, to succeed Dr. Tillisch as president-elect next year; Dr. Thomas H. Sutherland, Marion, Ohio, secretary-treasurer (reelected). The official history of the association, titled "Doctors in the Sky" by Dr. Robert J. Benford, Washington, D. C., was publicly released on the first day of the meeting. The following awards were made during the convention: Theodore C. Lyster award for achievement in the general field of aviation medicine to Gen. Otis O. Benson Jr., Washington, D. C.; the Raymond F. Longacre award to Dr. Roy R. Grinker, Chicago; and the Arnold D. Tuttle award to Fred A. Hitchcock, Ph.D., Columbus, Ohio. The 27th annual meeting of the association will be held at the Drake Hotel in Chicago, April 16-18, 1956.—— At the annual meeting of the **United States-Mexico Border Public Health Association** in Mexico City, the following officers were elected for 1956: Mr. George W. Marx, Phoenix, Ariz., president; Dr. Guillermo Soberanes, Hermosillo, Sonora, president-elect; Dr. Esteban de Essesarte, Agua Prieta, Sonora; Dr. Austin W. Matthis, El Centro, Calif., vice-president; and Dr. Sidney B. Clark, El Paso, Texas, secretary-treasurer.

FOREIGN

Symposium on Vitamin B_{12}.—Plans are being made for the first European symposium on vitamin B_{12} to be held the last week of May, 1956, in Hamburg, Germany. The physiology and the clinical application of vitamin B_{12} in human and veterinary medicine will be discussed. For information, write to Doz. Dr. H. Bauer, Nervenklinik, Hamburg-Eppendorf, Germany.

International Professional Union.—At a meeting in Paris, France, in June the official delegates of the National Professional Societies of Gynecologists and Obstetricians of the World founded the International Professional Union, of which Prof. Jean Ravina, Paris, is president, succeeding the president-founder, Dr. Maurice Fabre of Paris. The next international meeting will be in Madrid, Spain, Sept. 28-29, 1956. For information write to the secretary-general, Dr. Jacques Courtois, 1 rue Racine, St.-Germain-en-Laye (S. & O.), France.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

1956 Annual Meeting, Chicago, June 11-15.

1956 Clinical Meeting, Seattle, Nov. 27-30.

1957 Annual Meeting, New York, June 3-7.

National Medical Public Relations Conference, Hotel Statler, Boston, Nov. 28. Mr. Leo F. Brown, 535 N. Dearborn St., Chicago 10, Director.

American Academy of Dermatology and Syphilology, Palmer House, Chicago, Dec. 3-8. Dr. James R. Webster, 55 East Washington St., Chicago 2, Secretary.

American Academy of Neurological Surgery, The Homestead, Hot Springs, Va., Oct. 27-29. Dr. Eben Alexander Jr., Bowman Gray School of Medicine, Winston-Salem, N. C., Secretary.

American Academy of Obstetrics and Gynecology, Conrad Hilton Hotel, Chicago, Dec. 13. Dr. C. Paul Hodgkinson, 116 South Michigan Blvd., Chicago, Secretary.

American Association of Blood Banks, Palmer House, Chicago, Nov. 19-21. Miss Marjorie Saunders, 3707 Gaston Ave., Dallas 10, Texas, Secretary.

American Association of Medical Clinics, Curtis Hotel, Minneapolis, Nov 4-6. Dr. Edwin P. Jordan, Box 58, Charlottesville, Va., Executive Director.

American Association for the Surgery of Trauma, Drake Hotel, Chicago, Oct. 27-29. Dr. James K. Stack, 700 N. Michigan Blvd., Chicago 11, Secretary.

American Clinical and Climatological Association, The Homestead, Hot Springs, Va., Oct. 31-Nov. 2. Dr. M. N. Fulton, 124 Waterman St., Providence 6, R. I., Secretary.

American College of Anesthesiologists, Hotel Statler, Boston, Nov 4-5. Mr. John H. Hunt, 188 West Randolph St., Chicago 1, Executive Secretary.

American College of Cardiology Interim Meeting, Hotel Claridge, Memphis, Tenn., Nov. 10-12. Dr. Philip Reichert, Empire State Bldg., New York 1, Secretary.

American College of Gastroenterology, Hotel Shoreland, Chicago, Oct. 24-26. Dr. Joseph Shaiken, 33 West 60th St., New York 23, Secretary.

American College of Surgeons, Conrad-Hilton Hotel, Chicago, Oct. 31-Nov. 4. Dr. Michael L. Mason, 40 East Erie St., Chicago 11, Secretary.

American League Against Epilepsy, Roosevelt Hotel, New York, Dec. 8. Dr. Peter Kellaway, Baylor University College of Medicine, Houston 25, Tex., Secretary.

American Medical Women's Association, Board Meeting, Netherlands-Plaza Hotel, Cincinnati, Nov. 11-13. Miss Lillian T. Majally, 1790 Broadway, New York 19, Executive Secretary.

American Public Health Association, Muehlebach Hotel and Municipal Auditorium, Kansas City, Mo., Nov. 14-18. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

American School Health Association, Hotel President, Kansas City, Mo., Nov. 14-18. Dr. A. O. DeWeese, 515 East Main St., Kent, Ohio, Secretary.

American Society of Anesthesiologists, Hotel Statler, Boston, Oct. 29-Nov. 3. Dr. J Earl Remlinger Jr., Room 1101, 188 W. Randolph St., Chicago 1, Secretary.

American Society for the Study of Arteriosclerosis, Hotel Sheraton, Chicago, Nov. 6-7. Dr. O. J. Pollak, P.O. Box 228, Dover, Del., Secretary.

American Society of Tropical Medicine and Hygiene, Somerset Hotel, Boston, Nov. 2-5. Dr. John E. Larsh Jr., Dept. of Parasitology, School of Public Health, Chapel Hill, N. C., Secretary.

Association of American Medical Colleges, New Ocean House, Swampscott, Mass., Oct. 24-26. Dr. Dean F. Smiley, 185 N. Wabash Ave., Chicago 1, Secretary.

Association of Military Surgeons of the U. S., Hotel Statler, Washington, D. C., Nov. 7-9. Colonel Robert E. Bitner, 1726 I St. N.W., Washington 6, D. C., Secretary.

Association for Research in Nervous and Mental Diseases, Hotel Roosevelt, New York, Dec. 9-10. Dr. Clarence C. Hare, 710 West 168th St., New York 32, Secretary.

Association of State and Territorial Health Officers, Hotel Washington, Washington, D. C., Nov. 6-12. Dr. Franklin D. Yoder, State Board of Health, Cheyenne, Wyo., Secretary.

Central Society for Clinical Research, Drake Hotel, Chicago, Nov. 4-5. Dr. Robert H. Ebert, 950 East 59th St., Chicago 37, Secretary.

Congress of Neurological Surgeons, Hotel Statler, Los Angeles, Oct. 27-29. Dr. Philip D. Gordy, 1007 Delaware Ave., Wilmington, Del., Secretary.

Eastern Section, American Federation for Clinical Research, Hotel Warwick and College of Physician's Building, Philadelphia, Dec. 2-3. Dr. Charles R. Shuman, Temple Univ. Hospital, Broad and Ontario Sts., Philadelphia 40, Chairman.

Gerontological Society, Sheraton-Belvedere Hotel, Baltimore, Oct. 27-29. Dr. Nathan W. Shock, Baltimore City Hospitals, Baltimore 24, Secretary.

Gulf Coast Clinical Society, Pensacola, Fla., Oct. 27-28. Dr. Barkley Beidleman, 1750 N. Palafox St., Pensacola, Fla., Secretary.

Inter-Society Cytology Council, Statler Hotel, Cleveland, Nov. 11-12. Dr. Paul F. Fletcher, 634 N. Grand Blvd., St. Louis 3, Secretary.

Interstate Post Graduate Medical Association of North America, Municipal Auditorium, Milwaukee, Nov. 14-17. Mr. Roy T. Ragatz, 207 Gay Bldg., Madison 3, Wis., Executive Director.

Medical Society Executives Conference, Parker House, Boston, Nov. 27. Mr. H. Martin Baker, 1102 South Hillside, Witchita 17, Kansas, Secretary.

Midwestern Section of American Federation for Clinical Research, Thorne Hall, Northwestern University, and Drake Hotel, Chicago, Nov. 3. Dr. Robert J. Glaser, Barnes Hospital, St. Louis 10, Secretary.

National Association for Mental Health, Indianapolis, Nov. 4-6. Mr. Robert M. Heininger, 1790 Broadway, New York 19, Director.

New England Health Education Association, Boston, Dec. 2. Miss Wyntha Tompkins, Middlesex Health Association, Essex, Mass., Secretary.

Oklahoma City Clinical Society Conference, Oklahoma City, Oct. 24-27. Dr. Charles E. Leonard, 512 Medical Arts Bldg., Oklahoma City 2, Secretary.

Omaha Mid-West Clinical Society, Hotel Paxton, Omaha, Oct. 24-27. Mrs. Anne K. Ramsey, 1031 Medical Arts Bldg., Omaha 2, Executive Secretary.

Puerto Rico Medical Association, Santurce, Dec. 7-11. Dr. Luis R. Guzman-Lopez, Box 9111, Santurce, Secretary.

Radiological Society of North America, Palmer House, Chicago, Dec. 11-16. Dr. Donald S. Childs, 713 E. Genesee St., Syracuse 2, N. Y., Secretary.

Regional Meetings, American College of Physicians:

- Louisville, Ky., Nov. 5. Dr. Sam A. Overstreet, 332 West Broadway, Louisville, Ky., Governor.
- Newark, N. J., Nov. 9. Dr. Edward C. Klein Jr., 6 S. Kingsman Rd., South Orange, N. J., Governor.
- Detroit, Dec. 3. Dr. H. Marvin Pollard, 1313 East Ann St., Ann Arbor, Mich., Governor.
- Hot Springs, Ark., Dec. 3. Dr. A. A. Blair, 100 S. 14th St., Ft. Smith, Ark., Governor.
- Winston-Salem, N. C., Dec. 8. Dr. Elbert Persons, Duke Hospital, Durham, N. C., Governor.

Society of Clinical Surgery, Hotel Roosevelt, New Orleans, Nov. 11-12. Dr. Frank F. Allbritten Jr., University of Kansas Medical Center, Kansas City, Mo., Secretary.

Southern Medical Association, Shamrock Hotel, Houston, Texas, Nov. 14-17. Mr. V. O. Foster, 1020 Empire Bldg., Birmingham 3, Ala., Secretary-Manager.

Southern Society of Cancer Cytology, Houston, Texas, Nov. 14-17. Dr. J. Ernest Ayre, 1155 N.W. 14th St., Miami, Fla., Secretary.

Southern Surgical Association, The Homestead, Hot Springs, Va., Dec. 6-8. Dr. George G. Finney, 2947 St. Paul St., Baltimore 18, Secretary.

Southwestern Medical Association, Westward Ho Hotel, Phoenix, Ariz., Nov. 16-18. Dr. Celso C. Stapp, 800 Montana St., El Paso, Texas, Secretary.

State Medical Journal Conference, Chicago, Nov. 7-8. Mr. Alfred J. Jackson, 535 N. Dearborn St., Chicago 10, Director.

The Constantinian Society, Sheraton-Park Hotel, Washington, D. C., Oct. 26-29. Dr. C. F. Shook, P. O. Box 1035-36, Toledo 1, Ohio, Secretary.

Western Orthopedic Association, The Reef, Honolulu, Hawaii, Nov. 7-10. Dr. Ivar J. Larsen, 1133 Punchbowl, Honolulu 13, Hawaii, Secretary.

Western Society of Electro-Encephalography, Westward Ho Hotel, Phoenix, Ariz., Nov. 10-12. Dr. Sylvester N. Berens, 902 Boren Ave., Seattle, Secretary.

Western Surgical Association, Olympic Hotel, Seattle, Dec. 1-3. Dr. John T. Reynolds, 612 N. Michigan Blvd., Chicago 11, Secretary.

World Congress on Fertility and Sterility, Naples, Italy, May 18-26, 1956. For information address: Prof. G. Tesauro, S. Andrea della Dame, 19, Naples, Italy.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Various Centers. April 24-25 (Part II); June 19-20 (Parts I and II); September 4-5 (Part I). Candidates may file applications at any time but they must be received at least six weeks before the date of the examination for which application is made. New candidates should apply by formal registration; registered candidates may notify the board, indicating desired location, date and candidate number. Ex. Sec., Dr. John P. Hubbard, 133 South 36th St., Philadelphia 4.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 19-21. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery.

Arkansas:* *Examination.* Little Rock, Nov. 10-11. Sec., Dr. Joe Verser, Harrisburg.

California: *Oral and Clinical Examinations for Foreign Medical School Graduates.* San Francisco, Nov. 13. *Oral Examination for Reciprocity Applications.* San Francisco, Nov. 12. Sec., Dr. Louis E. Jones, Room 536, 1020 N St., Sacramento.

Colorado:* *Examination.* Denver, Dec. 6-7. Final date for filing application is Nov. 4. Exec. Sec., Mrs. Beulah H. Hudgens, 831 Republic Bldg., Denver 2.

Connecticut:* *Regular. Examination.* Hartford, Nov. 8-10. Sec., Dr. Creighton Barker, 160 St. Ronan St., New Haven. *Homeopathic.* Derby, Nov. 8-19. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby.

Delaware: *Examination.* Dover, Jan. 10-12. *Reciprocity.* Dover, Jan. 19. Sec., Dr. Joseph S. McDaniel, Dover.

Florida:* *Examination.* Miami Beach, Nov. 20-21. Sec., Dr. Homer L. Pearson, 901 N. W. 17th St., Miami.

Idaho: *Examination and Reciprocity.* Boise, Jan. 9-11. Exec. Sec., Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Indiana: *Examination.* Indianapolis, June. Exec. Sec., Miss Ruth V. Kirk, 538 K. of P. Bldg., Indianapolis.

Iowa:* *Examination.* Des Moines, Dec. 5-7. Ex. Sec., Mr. Ronald V. Saf, State Office Bldg., Des Moines.

Kansas: *Examination and Endorsement.* Topeka, Dec. 7-8. Sec., Dr. Lyle F. Schmaus, New Brotherhood Bldg., Kansas City.

Kentucky: *Examination.* Louisville, Dec. 5-7. Asst. Sec., Mr. R. F. Dixon, 620 S. 3rd St., Louisville.

Maine: *Examination and Reciprocity.* Portland, Nov. 8-9. Sec., Dr. Adam P. Leighton, 192 State St., Portland.

Maryland: *Examination.* Baltimore, Dec. 13-16. Exec. Sec., Miss Hannah A. McCarthy, 1215 Cathedral St., Baltimore 1.

Mississippi: *Reciprocity.* Jackson, December. Asst. Sec., Dr. R. N. Whitfield, State Board of Health, Jackson.

Nebraska:* *Examination.* Omaha, June 18-20. Director, Bureau of Examining Boards, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

New Mexico:* *Examination and Reciprocity.* Santa Fe, Nov. 21-22. Sec., Dr. R. C. Derbyshire, 227 E. Palace Ave., Santa Fe.

New York: *Examination.* Albany, Buffalo, New York City and Syracuse, Oct. 4-7. Sec., Dr. Stiles D. Ezell, 23 S. Pearl St., Albany.

North Carolina: *Reciprocity.* Asheville, Oct. 31. Sec., Dr. Jos. J. Combs, 716 Professional Bldg., Raleigh.

North Dakota: *Examination.* Grand Forks, Jan. 4-6. *Reciprocity.* Grand Forks, Jan. 7. Sec., Dr. C. J. Glaspel, Box 228, Grafton.

Ohio: *Examination.* Columbus, Dec. 15-17. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Oklahoma:* *Examination.* Oklahoma City, June 5-6. Sec., Dr. E. F. Lester, 813 Braniff Bldg., Oklahoma City.

Pennsylvania: *Examination.* Philadelphia, January. Acting Sec., Miss Marguerite G. Steiner, Box 911, Harrisburg.

South Carolina: *Examination.* Columbia, Nov. 7. Sec., Mr. N. B. Heyward, 1329 Blanding St., Columbia.

South Dakota:* *Examination.* Sioux Falls, Jan. 17-18. Exec. Sec., Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Texas:* *Examination and Reciprocity.* Galveston, Dec. 1-3. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

Virginia: *Examination.* Richmond, Dec. 7-9. *Reciprocity.* Richmond, Dec. 6. Final date for filing application is Nov. 21. Address the Secretary, 631 First St. S.W., Roanoke.

Wisconsin:* *Reciprocity and Examination.* Madison, Jan. 10-12; *Reciprocity,* Madison, Spring; *Reciprocity and Examination.* Milwaukee, July 10-12. Sec., Dr. Thomas W. Tormey, Jr., 1140 State Office Bldg., Madison.

Alaska:* On application. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

Guam: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Sec., Dr. John E. Kennedy, Agana.

Hawaii: *Examination.* Honolulu, Jan. 9-12. Sec., Dr. I. L. Tilden, 1020 Kapiolani, St., Honolulu.

Virgin Islands: *Examination and Endorsement.* St. Thomas, Nov. 8-9. Sec., Dr. Earle M. Rice, St. Thomas.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

District of Columbia: *Examination.* Washington, Oct. 24-25. Deputy, Mr. Paul Foley, 1740 Massachusetts Ave., N.W., Washington 6.

Florida: *Examination.* Gainesville, Nov. 5. Sec., Mr. M. W. Emmel, Box 340, Gainesville.

Oregon: *Examination.* Portland, Dec. 3; March 3; June 2, Sept. 8 and Dec. 1. Dr. Earl M. Pallett, Sec., State Board of Higher Education, Eugene.

South Dakota: *Examination.* Vermillion, Dec. 2-3. Sec., Dr. Gregg M. Evans, 310 E. 15th St., Yankton.

Wisconsin: Milwaukee, Dec. 3. Final date for filing application is Nov. 25. Madison, Apr. 7. Final date for filing application is Mar. 30. Sec., Dr. W. H. Barber, 621 Ransom St., Ripon.

Alaska: On application. Juneau or other towns in Territory as decided by Board. *Reciprocity.* On application. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

---

*Basic Science Certificate required.

MAGAZINE–TELEVISION REPORT

The following list of current medical articles in mass-circulation magazines and forthcoming network television programs on medical subjects is published each week only for the information of readers of The Journal. *Unless specifically stated, the American Medical Association neither approves nor disapproves of the articles and programs reported.*

TELEVISION

Monday, Oct. 24

NBC-TV, 11:30 a. m. EDT. "Medical and Health News with Howard Whitman," a segment of the "Home" program.

NBC-TV, 9 p. m. EDT. "Medic" presents "When I Was Young," a drama based on the problems of menopause and medicine's new methods of dealing with it.

ABC-TV, 9:30 p. m. EDT. "Medical Horizons" reports on the residency training program at Johns Hopkins Hospital, Baltimore.

Monday, Oct. 31

NBC-TV, 9 p. m. EST. "Medic" turns to recent history for its presentation on aviation medicine. Titled "The World So High," the drama tells how William Lovelace, Army doctor, parachuted from a plane eight miles above the earth to test the effects of high altitude on the human system.

MAGAZINES

Life, Oct. 10, 1955

"Heart Attack"

A detailed report on the cause and effect of a heart attack illustrated with anatomic drawings and photographs. The presentation also includes a profile on Dr. Paul Dudley White and a summary of research into the disease.

Woman's Home Companion, November, 1955

"The Epoch Approach to Child Development," by Dr. Milton J. E. Senn with Evan McLeod Wylie

The director of Yale's Child Study Center questions the "rigidities" of pediatric theories that try to match children to "growing-up timetables." He feels instead "that each child will have a mind all his own which will respond individually to the way in which he is nurtured, reared and educated."

Pageant, November, 1955

"You're Giving Yourself That Headache," by Henry Lee

The author says that several researchers have been working out a system of preventive therapy for headaches based on the theory that long-time sufferers "have made it a habit to get headaches regularly." A "headache preventive therapist" first helps the patient "lower the weight of tension being carried" and, with medication, "stiffens the trigger so that it will take more tension to go off." The article mentions Gynergen Dihydroergotamine (D.H.E.-45) and a "pill combination of caffein and ergot," all produced by Sandoz Pharmaceuticals.

Better Living, November, 1955

"Chart of Common Childhood Illnesses," compiled by Dr. Harry S. Altman

As part of a continuing series published under the supervision of the New York Academy of Medicine, the author lists common childhood ailments and gives data on cause, treatment, and prevention.

Family Circle, November, 1955

"Pity the Poor Snorer," by Frances Gibson Satterfield

"Can anything be done to prevent snoring? Medical papers at various times have recommended a number of remedial steps, at the same time admitting they are often ineffectual." The author summarizes ideas on the subject.

GOVERNMENT SERVICES

PUBLIC HEALTH SERVICE

Supply of Poliomyelitis Vaccine.—HEW Secretary, Marion B. Folsom, announced Oct. 2 that enough poliomyelitis vaccine has been released to give two injections to three-fourths of the nation's children in the 5-9 age group. He said definite predictions are not possible, but present indications are that enough vaccine will be released to give two injections to all the 15,903,000 children in this top priority group by Dec. 31. It would take about 32 million cc. to give every child in the 5-9 age group two injections. The National Institutes of Health, Public Health Service, has released 23,812,596 cc. since the program started in April. This leaves less than 9 million cc. needed to complete two injections for each child in this age group. Of the vaccine released so far, about 13 million cc. have been released to the National Foundation for Infantile Paralysis for its program of free vaccinations for second and third grade school children. About 10 million cc. have been released to states and territories under the voluntary control program, 53% of this going to commercial channels and 47% to public agencies.

Secretary Folsom pointed out that while production and clearance of the vaccine is being expedited, research continues to seek possible improvements in the vaccine testing and manufacturing processes. This research program is being done under the joint auspices of the National Foundation for Infantile Paralysis, the vaccine manufacturers, and scientists in medical schools and universities, and the Public Health Service and its technical advisory committee. He said that after the immediate needs of the 5-9 age group have been met, vaccine will be made available to other age groups most susceptible to poliomyelitis. The age group priority recommendations are made by the National Advisory Committee on Poliomyelitis Vaccine, which counsels the Department of Health, Education, and Welfare on matters of distribution and allocation. This committee will be convened soon to consider the next priority group.

Plans for Distribution of Free Poliomyelitis Vaccine.—Surgeon General Scheele announced on Sept. 28 the approval of plans submitted by 22 states and territories for use of federal funds to distribute free poliomyelitis vaccine. An additional 16 plans have been received from states and territories and are being reviewed. The states and territories with approved plans are Arizona, Colorado, Delaware, Kansas, Kentucky, Louisiana, Minnesota, Missouri, Nebraska, New York, North Carolina, North Dakota, Ohio, Oklahoma, South Dakota, Tennessee, Texas, Utah, Virginia, Wisconsin, Hawaii, and the Canal Zone. These states can start drawing immediately on $13,119,508 of the 30 million dollars that Congress appropriated for purchase and administration of vaccine.

Under the Poliomyelitis Assistance Act, all states are entitled to receive grants under a formula based on the cost of vaccine, the state's per capita income, and its population of children under 20, and pregnant women. Judging from the plans already approved, the poliomyelitis programs will be handled much the same as other state immunization programs, and plans will vary from community to community. Some counties and cities will hold public clinics; some will rely chiefly on private physicians; and many will make the vaccine available both in public clinics and to private physicians. In communities that lack local health departments, the program will be administered by the state health department or the local medical profession.

The federal law provides that states may determine methods of distributing the vaccine between public and commercial channels. In most states, some vaccine will be distributed through both channels and physicians will have some vaccine available from the public supply as well as from commercial outlets. Where the public vaccine is used in public programs, no means test can be used to limit the persons who are eligible for free vaccinations. The Public Health Service is responsible for allocating vaccine (as distinguished from funds) to states according to the percentage of children in an eligible age group who live in each state. State plans indicate an almost complete acceptance of the 5 to 9 age priority recommended by the National Advisory Committee on Poliomyelitis Vaccine.

Under the federal aid program, states have an option of buying their own vaccine or of obtaining federally purchased vaccine in lieu of cash. Early plans indicate that most of them plan to buy their own vaccine. They will receive their federal payments in monthly installments. States also have the option of using all of their share of the 30 million dollars for purchase of the vaccine or of reserving up to one-sixth for administrative costs, such as cost of conducting public clinics. Many of the states have indicated that they will spend all of their share for vaccine purchase.

Grants for Research in Hospital Services.—A program of grants for research in hospital services and facilities has been initiated by the Public Health Service. Grants from funds appropriated to the Department of Health, Education, and Welfare will be made to qualified nongovernmental research scientists, on the recommendation of the Federal Hospital Council. Grants will be awarded for research into: (1) the needs for hospital and related services; (2) measurement of resources to meet these needs; (3) hospital and medical facilities planning, both in relation to community needs and resources, and to architectural and design aspects; (4) methods of increasing the availability and effectiveness of hospital services and of improving the quality of these services; and (5) methods by which hospital services can be improved or costs lowered through coordination on a regional or other basis. Inquiries and applications for grants should be addressed to the Division of Research Grants, National Institutes of Health, Bethesda, Md.

Research on Air Pollution.—The Public Health Service has announced grants totaling $295,367 to start a special program of research into air pollution problems that Surgeon General Scheele hopes will answer many puzzling questions and help eliminate many dangers from air pollution. The 10 grants were awarded by the surgeon general on recommendations of the National Advisory Health Council from a $500,000 fund appropriated by Congress this year.

"There has been increasing evidence that various types of air pollution may constitute a serious, widespread danger to human health," Dr. Scheele said. "To what degree this is so, in just what way the human body may be damaged by different air pollutants in different concentrations, is therefore a matter of deep concern to us. These and other studies over the period of the next few years should provide some of the answers."

VETERANS ADMINISTRATION

Residents in Psychiatry Wanted.—The Veterans Administration Hospital, Hines, Ill., still has openings for resident physicians in psychiatry, beginning at any time but preferably at the start of each quarter for the current fiscal year. The hospital is a large training center that is accredited for training in 18 specialties of medicine. It is within easy commuting distance of various psychiatric facilities in Chicago. The deans' committee is comprised of the four local medical schools. The training program is well rounded and accredited for full training.

Dr. J. E. Davis Retires.—John Eisele Davis, Sc.D., retired from the Veterans Administration Sept. 30 after 35 years of government service and will now devote himself to teaching, lecturing, and writing. Dr. Davis has been a pioneer in development of recreation for the treatment of mental patients. He is the author of several books and manuals on medical rehabilitation and on corrective and recreational therapy as psychotherapeutic-activity approaches. He is said to have written the first book on recreational therapy published in this country in collaboration with Dr. William R. Dunton, associate professor of psychiatry at Johns Hopkins Medical School. He was the founder of the Association for Physical and Mental Rehabilitation which now has chapters in every state. His most recent book, "Clinical Applications of Recreational Therapy," was published in 1952. Dr. Davis' winter home is at Keystone Heights, Fla.

DEATHS

Lyon, James Alexander ⊕ Washington, D. C.; born in Deposit, N. Y., Feb. 28, 1882; Maryland Medical College, Baltimore, 1906; subsequently studied in London, Vienna, and at Harvard; *interned at Franklin Square and Bay View City hospitals* (rotating service) Baltimore, 1906-1907; resident physician Loomis Sanatorium in Liberty, N. Y., 1907-1909; later senior resident physician and assistant superintendent at the Massachusetts State Sanatorium in Rutland; served as a first lieutenant, captain, and major in the Medical Corps of the U. S. Army from 1916 to 1925; first served on the Mexican Border and later with the American Expeditionary Forces in France, participating in the battles of Champagne-Marne, Aisne-Marne (Belleau, Château-Thierry), St. Mihiel, Ile de France, Lorraine, Defense of Toul, and Meuse-Argonne; later, served as post surgeon for the third U. S. Infantry, Fort Wayne, Detroit; his military honors included the Silver Star, Purple Heart, Congressional Selective Service medal, Mexican Border Service medal, the Victory medal with five major battle campaign clasps, and the French Croix de Guerre; first secretary and third president of the Washington Heart Association; member of the Association of Military Surgeons of the United States and the American Heart Association; fellow of the American Association for the Advancement of Science, American College of Chest Physicians, and the New York Academy of Medicine; life member of the American College of Physicians; professor of clinical cardiology at Georgetown University School of Medicine from 1929 to 1940; specialist certified by the American Board of Internal Medicine; consulting cardiologist at the Doctors Hospital, where he was a member of the executive and teaching staff; cardiologist at Sibley Memorial Hospital; for many years on the staffs of the Georgetown University Hospital, Children's Hospital, and the Emergency Hospital, where he died Aug. 3, aged 73, of adenocarcinoma of the sigmoid colon.

Kitchin, Thurman Delna ⊕ Wake Forest, N. C.; born in Scotland Neck, N. C., Oct. 17, 1885; Jefferson Medical College of Philadelphia, 1908; in 1917 became professor of physiology at Wake Forest College, where he was president from 1930 to 1950, after which he became professor of physiology and hygiene at the Wake Forest School of Medicine, serving as dean for many years; past-president of the Medical Society of the State of North Carolina and the Sixth District Medical Society; fellow of the American College of Physicians and the American Association for the Advancement of Science; member of the Southern Medical Association, Tri-State Medical Society, Omicron Delta Kappa, Delta Kappa Epsilon, Phi Chi, and Phi Beta Kappa; in 1925 appointed by Governor McLean a member of a special committee to study the problem of the feebleminded in North Carolina; member of the Veterans Administration special committee on rehabilitation and education problems; *member of the North Carolina advisory council of the unemployment* compensation commission; chairman of the North Carolina advisory council for the employment security commission; representative of the Association of American Colleges Advisory Council on Medical Education; member of board of directors of the North Carolina Sanatorium for the Treatment of Tuberculosis in McCain; received honorary degrees of doctor of law from Duke University, Durham, University of North Carolina, Chapel Hill, and Davidson (N. C.) College; author of "Lectures on Pharmacology," "The Doctor and Citizenship," and "Doctors in Other Fields"; died Aug. 28, aged 69, of a heart attack.

Cheever, David ⊕ Boston; born in Boston June 25, 1876; Harvard Medical School, 1901; associate professor of surgery *emeritus at his alma mater, where he joined the faculty in 1913;* served as a lieutenant colonel in the British Expeditionary Force during World War I; past-president of the American Surgical Association, New England and Boston Surgical societies, and the Boston Medical Library; from 1940 to 1946 a member of the board of overseers of Harvard University and was a vice-president of the Harvard Alumni Association; fellow of the American Academy of Arts and Sciences and the Massachusetts Historical Society; honorary fellow of the Royal Society of Medicine, London, and the Society of Surgery of Argentina; Bevan lecturer, Chicago Surgical Society (1939), and Balfour lecturer, University of Toronto (1941); member of the founders group of the American Board of Surgery; for many years on the staffs of the Boston City and Peter Bent Brigham hospitals; died at his summer home in Wellesley Aug. 13, aged 79, of heart disease.

Gillespie, Noel Alexander, Madison, Wis.; born in London, England, Dec. 25, 1904; *M.B., University of Oxford School of* Medicine, England, 1931, and M.D., in 1935; University of Wisconsin Medical School. Madison, 1945; after serving on the staffs of several British hospitals between 1934 and 1939, joined the faculty of the University of Wisconsin Medical School to occupy in turn the positions of resident, research associate, assistant professor, and associate professor of anesthesia; fellow of the Royal Society of Medicine, the Royal College of Surgeons, *and the International College of Anesthetists; corresponding* member of the Société française d'anesthésie; member of the American Society of Anesthesiologists, the Canadian Anesthetists' Society, and the Association of Anesthetists of Great Britain and Northern Ireland; author of "Endotracheal Anaesthesia"; died in the University Hospitals Aug. 21, aged 50, of myocardial infarction.

Porter, John McGill ⊕ *Concordia, Kan.; born in Kansas City* Aug. 13, 1899; Harvard Medical School, Boston, 1926; interned at the Henry Ford Hospital in Detroit; from 1948 to 1953 member of the House of Delegates of the American Medical Association; president of the Kansas Medical Society, of which he was elected second vice-president in 1952, and in 1953 first vice-president; for eight years previously held the office of secretary of this society; past-president of the Cloud County Medical Society and the Kansas Heart Association; during World War II served in the U. S. Naval Reserve for four years and was discharged with the rank of captain; during World War I was a second lieutenant in the field artillery; in 1947 resigned as health officer of Cloud County to accept an appointment as a member of the state board of health; died Sept. 5, aged 56, of acute pancreatitis.

Pillsburg, Henry Church ⊕ Brigadier general, U. S. Army, retired, Ross, Calif.: born in Lowell, Mass., May 27, 1881; Harvard Medical School, Boston, 1906; fellow of the American College of Physicians and the American College of Surgeons; member of the Asssociation of Military Surgeons of the United States; entered the regular Army in 1907; served during World Wars I and II; became a lieutenant colonel in 1927 and a colonel in *1933; major assignments included direction of medical services* in the Panama Canal Zone, service as director of x-ray facilities at Walter Reed Hospital, Washington, D. C., and command of the Lovell General Hospital in Fort Devens, Mass., and the Thayer General Hospital in Nashville, Tenn.; retired May 31, 1945; died July 18, aged 74, of a heart attack.

Shaw, Arthur Briggs, Altadena, Calif.; born in Joliet, Ill., April 28, 1886; Dartmouth Medical School, Hanover, N. H., 1911; interned at Boston City Hospital, and the Willard Parker Hospital and New York Lying-In Hospital in New York City; formerly practiced in Longview, Wash., where he was president of the Cowlitz County Medical Association for two terms and was one of the founders of the Cowlitz General Hospital, serving on its board for several years; died in the Collis P. and Howard Huntington Memorial Hospital in Pasadena July 18, aged 69, of myocardial infarction.

⊕ Indicates Member of the American Medical Association.

Aurand, William Henry ⊕ Minneapolis; University of Minnesota College of Medicine and Surgery, Minneapolis, 1901; member of the American Academy of General Practice; in 1938 became chief of staff of St. Barnabas Hospital; died in the Franklin Hospital July 17, aged 80, of carcinoma of the bladder with multiple bone metastases.

Bagwell, Robert Wayne ⊕ Borger, Texas; University of Texas School of Medicine, Galveston, 1941; interned at the Baltimore City Hospital; formerly a resident at the Brackenridge Hospital in Austin; served in the U. S. Naval Reserve during World War II; died May 23, aged 38, of coronary thrombosis.

Bennett, Francis Paul ⊕ Alliance, Ohio; University of Cincinnati College of Medicine, 1922; interned at the Wheeling (W. Va.) Hospital; for many years a member and at one time president of the staff of the City Hospital; died in the University Hospitals, Cleveland, June 26, aged 61, of abdominal cancer.

Bibb, James Porter, Montgomery, Ala.; University of Nashville Medical Department, 1907; died July 20, aged 75, of arteriosclerosis.

Blanchard, Florence Estelle Crummett, Windsor, Vt.; College of Physicians and Surgeons; Boston, 1911; died June 29, aged 71, of cerebral thrombosis.

Bowman, Delbert J. ⊕ Lincoln, Neb.; Cotner University Medical Department, Lincoln, 1911; for many years on the staff of St. Elizabeth Hospital; died Aug. 4, aged 73.

Briscoe, Benjamin E., Willcox, Ariz.; University of Tennessee Medical Department, Nashville, Tenn., 1901; served on the school board and state legislature; died in Phoenix July 29, aged 78, of cancer of the mouth.

Browning, Eugene Shelley ⊕ Grand Rapids, Mich.; Detroit College of Medicine, 1905; at one time on the faculty of Grand Rapids Medical College; on the staffs of the Blodgett and St. Mary's hospitals; died in Butterworth Hospital July 7, aged 74, of cerebral hemorrhage and hypertension.

Carson, James Green ⊕ Clarksdale, Miss.; Columbia University College of Physicians and Surgeons, New York City, 1893; died Aug. 18, aged 86.

Cleary, Joseph P. ⊕ Minotola, N. J.; Bennett Medical College, Chicago, 1913; veteran of the Spanish-American War and World War I; on staff of Lankenau Hospital in Philadelphia; died in Atlantic City, N. J., Aug. 7, aged 73, of a heart attack.

Cooper, Irving Joseph ⊕ New Brunswick, N. J.; Georgetown University School of Medicine, Washington, D. C., 1928; on the staff of St. Peter's Hospital, where he served an internship and where he died Aug. 4, aged 52, of cerebral thrombosis, coronary thrombosis, and diabetes mellitus.

Dillard, James Albert, Waurika, Okla.; University of Arkansas School of Medicine, Little Rock, 1910; county health director; died in the Waurika Hospital July 30, aged 70, of a heart attack.

Edahl, Edwin Waldamar ⊕ Van Horn, Texas; University of Illinois College of Medicine, Chicago, 1930; interned at the Wesley Memorial Hospital in Chicago; served during World War II; at one time on the staff of the Veterans Administration Hospital in Amarillo; formerly associated with the New Mexico Health Department; died in El Paso June 8, aged 62, of acute myocardial infarction.

Gillespie, Julian Mason, surgeon, U. S. Public Health Service, retired, Richmond, Va.; University of Maryland School of Medicine, Baltimore, 1909; retired Nov. 25, 1930; died in Baltimore July 27, aged 73, of subdural hemorrhage.

Greer, Neil E. ⊕ Lockney, Texas; Fort Worth School of Medicine, Medical Department of Texas Christian University, 1914; died June 26, aged 72.

Hess, Peter William, Dexter, Maine; Harvard Medical School, Boston, 1901; died in the Plummer Memorial Hospital Aug. 6, aged 80, of myocardial failure.

Holmes, Alfred Wellwood, Detroit; Detroit College of Medicine, 1910; member of the Michigan State Medical Society; died in the Lincoln Hospital June 22, aged 68, of coronary thrombosis.

Holmes, John Franklin ⊕ Manchester, N. H.; Tufts College Medical School, Boston, 1909; formerly chairman of the board of health; fellow of the American College of Surgeons; served on the staffs of the Elliot Hospital in Manchester, the Hillsboro County General Hospital in Grasmere, the Alexander-Eastman Hospital in East Derry, Pembroke Sanatorium in Concord, Exeter (N. H.) Hospital, and Waldo County General Hospital in Belfast, Maine; died June 19, aged 76, of pulmonary embolism and pneumonia.

Honigsberg, Leo ⊕ Miami Beach, Fla.; University and Bellevue Hospital Medical College, New York City, 1928; boxing commission physician from 1942 to 1953; police surgeon for the North Miami police department since 1949; on the staff of St. Francis Hospital, where he died July 6, aged 52, of coronary occlusion with myocardial infarction.

Howell, Robert, Traverse City, Mich.; Detroit College of Medicine, 1892; for many years assistant superintendent of the Eloise (Mich.) Hospital; died in the James Decker Munson Hospital July 29, aged 90.

Kahn, Isidor Nathan, New York City; University and Bellevue Hospital Medical College, New York City, 1907; member of the Medical Society of the State of New York; formerly associated with Gouverneur, Bronx, and Bellevue hospitals; died Aug. 11, aged 75, of carcinoma of the stomach.

Kornbluh, Ignatius ⊕ New York City; University and Bellevue Hospital Medical College, New York City, 1906; an associate member of the American Medical Association; served on the staffs of the Misericordia and Lenox Hill hospitals; died June 22, aged 75, of coronary thrombosis.

Lazarus, Benjamin ⊕ Newton, Mass.; Harvard Medical School, Boston, 1899; died Aug. 15, aged 78, of coronary thrombosis.

Leighton, Isaac Wellman, Iowa City; Northwestern University Medical School, Chicago, 1909; associate professor of anatomy at the State University of Iowa College of Medicine; died in the Mercy Hospital Aug. 4, aged 70, of coronary thrombosis.

Lemberg, Leon, New York City; New York University Medical College, New York City, 1898; died July 27, aged 86, of heart disease.

Lutterloh, Isaac Sr., Sanford, N. C.; Vanderbilt University School of Medicine, Nashville, Tenn., 1890; died June 6, aged 89, of chronic myocarditis.

McCarthy, James Matthew ⊕ Woonsocket, R. I.; Harvard Medical School, Boston, 1917; interned at St. Joseph's Hospital in Providence; served during World War I; past-president of the Woonsocket District Medical Society; on the staff of the Woonsocket Hospital; died in the Phillips House of Massachusetts General Hospital, Boston, July 26, aged 64.

McCarthy, Ralph Rowland, Downey, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1911; died June 9, aged 71, of pulmonary edema and emphysema.

McCorkle, William Pyles ⊕ Bridgeville, Pa.; Jefferson Medical College of Philadelphia, 1897; an associate member of the American Medical Association; died in the Allegheny General Hospital, Pittsburgh, June 11, aged 85, of coronary occlusion.

Michie, Winston Thomas, Memphis, Tenn.; University of Virginia Department of Medicine, Charlottesville, 1898; died in the Baptist Hospital July 28, aged 82, of pulmonary abscess and cystic nephritis.

Miley, Weir Mitchell ⊕ Anderson, Ind.; Jefferson Medical College of Philadelphia, 1910; past-president of the Madison County Medical Society; served overseas during World War I; in August, 1927, became a member of the school board, of which he had been treasurer, secretary, and president; died July 26, aged 69, of asthma and heart block.

Mitchell, Frank Baxter, Crescent, Ga.; Medical School of Maine, Portland, 1901; New York Homeopathic Medical College and Hospital, New York City, 1905; at one time associated with the Milledgeville (Ga.) State Hospital; died in Savannah, July 3, aged 78.

Moon, Arthur Ernest ⊕ Temple, Texas; University of Texas School of Medicine, Galveston, 1920; fellow of the American College of Physicians; for many years associated with Scott and White Memorial Hospital; died July 27, aged 65, of a heart attack.

Morris, William Francis ⊕ Princeton, Ind.; Jefferson Medical College of Philadelphia, 1900; county coroner for two terms; formerly health officer of Fort Branch; died April 22, aged 79, of coronary thrombosis, hypertension, and arteriosclerosis.

Mudge, Murray Fairbanks, Newfane, N. Y.; Niagara University Medical Department, Buffalo, 1895; veteran of the Spanish-American War and World War I; died July 23, aged 85.

O'Connor, Roderic Patrick ⊕ Oakland, Calif.; University of Pennsylvania Department of Medicine, Philadelphia, 1900; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology and the Pacific Coast Oto-Ophthalmological Society; for many years an officer in the regular Army; on the staff of the Providence Hospital; a consultant for Children's Hospital of the East Bay; died in Carmel July 6, aged 77, of myocardial infarction.

Pieper, Henry G. ⊕ St. Louis; St. Louis University School of Medicine, 1903; also a registered pharmacist; died July 25, aged 76, of injuries received in an automobile accident.

Purtle, Christopher Columbus, Little Rock, Ark.; University of Arkansas School of Medicine, Little Rock, 1907; served as superintendent of the Pulaski County Hospital; died in St. Vincent's Infirmary June 26, aged 76, of coronary occlusion and peptic ulcer with hemorrhage.

Reed, James Ross, Altadena, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the International College of Surgeons and the American College of Surgeons; served during World War I; on the staffs of the St. Luke Hospital and the Collis P. and Howard Huntington Memorial Hospital; died May 11, aged 75, of cerebral embolus.

Robertson, Arthur Edward, Dana, Ind.; The Hahnemann Medical College and Hospital, Chicago, 1910; died in Pontiac, Mich., July 7, aged 80.

Rosander, Phyllis, Minneapolis; University of Minnesota Medical School, Minneapolis, 1950; interned at Minneapolis General Hospital; formerly a fellow in obstetrics and gynecology at the University of Minnesota; served a residency at Sanford Hospital in San Francisco; killed in an automobile accident near Knolls, Utah, May 29, aged 34.

Rubenstein, Louis G. ⊕ Pittsburgh; University of Pittsburgh School of Medicine, 1899; an associate member of the American Medical Association; a founder and for many years on the staff of the Braddock General Hospital; died Aug. 21, aged 84.

Schultz, J. William ⊕ Tremont, Pa.; Medico-Chirurgical College of Philadelphia, 1895; an associate member of the American Medical Association; for many years deputy coroner; on the staff of the Pottsville (Pa.) Hospital; died July 27, aged 82, of acute myocardial infarction.

Small, Frederick Rieth ⊕ Newburgh, N. Y.; University and Bellevue Hospital Medical College, New York City, 1931; interned at the Knickerbocker Hospital in New York City; fellow of the American College of Surgeons; member of the New York Academy of Medicine; served during World War II; chief of surgery of St. Luke's Hospital; consulting surgeon, Highland Hospital in Beacon; died in Skytop, Pa., July 20, aged 57, of coronary occlusion.

Stark, Charles Vernon, Harlan, Ky.; Tennessee Medical College, Knoxville, 1900; died June 1, aged 76.

Stevenson, Eber Fortner ⊕ Waterloo, Iowa; Jefferson Medical College of Philadelphia, 1904; died July 11, aged 81, of coronary heart disease.

Stork, A. Robert ⊕ Logan, W. Va.; Medical College of Virginia, Richmond, 1935; died Sept. 11, aged 44, of pneumonia.

Stoutamire, Fred A., Richmond, Va.; University College of Medicine, Richmond, 1911; anesthetist at the Retreat for the Sick; died July 23, aged 67, of acute coronary thrombosis.

Streeter, Frederick B., Glens Falls, N. Y.; Albany (N. Y.) Medical College, 1879; served as health officer of the village of Glens Falls and the town of Queensbury and as coroner of Warren County; formerly member of the board of education; on the honorary staff of the Glens Falls Hospital; died Aug. 25, aged 101, of arteriosclerosis.

Swift, Robert Howard ⊕ Orinda, Calif.; Washington University School of Medicine, St. Louis, 1943; interned at St. Mark's Hospital in Salt Lake City; formerly a resident at the Ellis Fischel State Cancer Hospital in Columbia, Mo., and the Permanente Foundation Hospital in Oakland; died July 28, aged 38.

Switzer, John Franklin, New Straitsville, Ohio; Eclectic Medical Institute, Cincinnati, 1893; died in Mount St. Mary's Hospital in Nelsonville July 10, aged 89, of cancer.

Thompson, William Albert, Stigler, Okla.; College of Physicians and Surgeons, Little Rock, 1909; formerly associated with the Indian Service; died Aug. 11, aged 81.

Thompson, William Graham ⊕ Andover, Mass.; Harvard Medical School, Boston, 1933; on the staffs of Bon Secours Hospital in Methuen, and Lawrence (Mass.) General Hospital; died Aug. 13, aged 49, of idiopathic pulmonary edema.

Trooien, Peter O., Eagle Grove, Iowa; Minneapolis College of Physicians and Surgeons, 1906; died Aug. 2, aged 81, of Hodgkin's disease.

Troutman, Holmes Fielding ⊕ Huntington, W. Va.; University of Pennsylvania Department of Medicine, Philadelphia, 1908; formerly chief surgeon at the Queens Hospital in Honolulu; died in the Memorial Hospital Aug. 16, aged 74, after a cerebral hemorrhage.

Voislawsky, Van Rensselaer, New York City; Columbia University College of Physicians and Surgeons, New York City, 1929; interned at the St. Luke's Hospital, where he was later on the staff; formerly a resident physician at the Bellevue Hospital; certified by the National Board of Medical Examiners; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; died Aug. 29, aged 51, of pneumonia.

Walker, Arthur Wellington ⊕ Riverside, Calif.; John A. Creighton Medical College, Omaha, 1904; an associate member of the American Medical Association; fellow of the American College of Surgeons; died in Santa Ana July 5, aged 81, of coronary thrombosis.

Wall, John Alexander, San Antonio, Texas; University of the South Medical Department (Sewanee Medical College), Sewanee, Tenn., 1899; died in Houston May 11, aged 81, of cerebral vascular accident.

Wenzinger, Harold John ⊕ Defiance, Ohio; University of Louisville (Ky.) School of Medicine, 1937; secretary of the Defiance County Medical Society; member of the American Academy of General Practice; served during World War II; physician for Defiance College; on the staff of the Defiance Municipal Hospital; died in an automobile accident near Greensburg, Ind., Aug. 25, aged 45.

Whitaker, William Jerry, Dallas, Texas; University Medical College of Kansas City, Mo., 1900; served during World War I; at one time practiced in Pryor, Okla., where he founded a hospital bearing his name, and was physician to the Whitaker Orphans' Home; died in the Methodist Hospital Aug. 2, aged 74, of coronary occlusion with myocardial infarction.

Wilkinson, Stella Lucy ⊕ St. Paul; University of Minnesota College of Medicine and Surgery, Minneapolis, 1903; served on the staffs of the Moose Lake (Minn.) State Hospital and the Minnesota School and Colony in Faribault, Minn.; died in Midway Hospital July 22, aged 81, of coronary sclerosis and cholelithiasis.

FOREIGN LETTERS

AUSTRIA

Physicians' Strike.—On June 18, 1955, nearly 50% of the active physicians from all parts of Austria went to Vienna to participate in a protest against the proposed general social security bill (ASVG). On Aug. 25 and 26, all the Austrian physicians (practitioners, specialists, hospital physicians, professors, and assistants) went on strike. A well-organized emergency service was established so that no patient remained without emergency care. The ASVG deeply affects the free professional activities of the physicians and greatly limits the rights of the insured persons. The law would mean the end of any noteworthy private practice and would also mean the creation of a monopoly in the field of health by the main body of carriers of social insurance.

Development of Health Insurance in Austria.—Out of the Christian "Caritas" of the Middle Ages, community organizations have evolved to help the medically indigent. Guild funds were created to provide for a balance of risks. The Miners' Funds is an outgrowth of one of these. From such sources large-scale health insurance developed in the 1880's. In 1888 a health insurance law made this insurance obligatory for workmen in industry, traffic, and trade. In the beginning, these insurance funds were simple and economic; the number of employees was small and the contacts between insured persons, physicians, and employees were personal and close. The claims of the insured persons were reasonable, and the physicians worked for a small fixed salary and were able to compensate their low fees with their income from private practice. The industrial revolution brought about a rapid extension of health insurance. Although the loss of World War I, the dismemberment of the Austrian Empire, and the resulting breakdown of the currency caused a severe shock to the insurance funds, they were kept alive. The employee insurance law of 1926, for the first time, combined health insurance with the other branches of social insurance for employees in private business; a similar law for the laborers was enacted, but, because of the bad economic conditions at this time, no attempt was made to enforce it. In the meantime 31 amendments were added to the original law. A law for the agricultural workers gave sickness, accident, invalidism, and old age insurance to this group, and all federal employees were similarly insured. A new system of contract physicians was initiated by some of the funds. This system gave the insured persons the right of free choice of their physician. The number of insured persons snowballed; free practice shrank from day to day; and the physicians became more and more dependent on the insurance funds.

Value of Social Security.—In the 40 years of its existence (1895 to 1935) social security had proved its value and its superiority over private charity and private services for the poor. The feeling of security even when the insured person claimed no benefits, the certainty of being protected from the first day of an illness, and the feeling of ease about the welfare of one's family impressed the employee that he was getting something in return for his high premiums. The employers too appreciated the partial release from liability worries, the assurance of the worker's return after his recovery, and the increased work capacity of the worker due to better medical care. From the viewpoint of political economy, it was important that thousands of people in times of disease did not fall out as customers; the sales remained constant and millions of schillings were flowing back into the economic life of the country through insurance fund payments. For the physician there was the advantage that his insurance salary, even though reduced, was assured. Furthermore the emphasis on disease and accident prevention was beneficial. The government considered the social security of large masses of the population as the most effective dike against restlessness, revolution, and chaos.

In a situation in which unemployment deprived the insurance funds of their support, the threat of civil war paralyzed industry and the economic position of the physicians reached a low point. An industrial social insurance law was therefore enacted in 1935. It contained all those characteristics that in the course of World War II came to be called "social security" in the allied countries. Social security in the form of unemployment benefits weakens the private insurance principle. Health insurance is truly insurance, but unemployment insurance is a public social service. In the period between the two world wars, inflation had destroyed the security reserves as well as the economically valuable connections of the empire. The private insurance companies coldly insisted on the principle of "a crown is a crown," since their capital had been proportionately devaluated. The social security agency, however, had to revaluate all the pensions and had at least to adjust the sickness benefits. Under the economic circumstances that prevailed at this time, increased premiums (obligatory contributions) or federal subsidies were out of the question and unemployment was a great burden to the budget. There was, therefore, only one way, i. e., to reduce the benefits. No extension of insurance to new groups was possible. The law of 1935 now appears as an outstanding achievement professionally and socially, which restored the balance between revenues and expenses in social security, relieved the most acute suffering, and separated true social insurance from the tasks belonging to the social service. In many details the administration was simplified; premiums were based on a certain percentage of wages. Most important, the law placed the physicians and their organizations as partners, with rights equal to those of the insurance funds in the National Committee, the Committee for Physician's Help, and other special committees. In these committees, the number of representatives from the national association of the social insurance carriers and from the members of the legal representative body for the interests of the physicians was the same. These committees settled all the important basic problems by arbitration.

Changes After Occupation of Austria.—The occupation of Austria by Nazi Germany in 1938 gave the German National Social Insurance Law legal force in Austria. The autonomy of the social security agency was abolished, and the Association of Fund Physicians became the highest authority. In spite of the difficulties that were brought about by World War II, the health insurance program continued to function and the physicians were satisfied, although they objected to some of the authoritarian interventions by the government. After 1945 an Austrian type of health insurance was reestablished and the autonomy of the insurance funds was restored, but at this time the physicians had no legal representatives. They expected that the tradition of the previously existing industrial social security law, which had proved its value, would be continued, but that was not the case. The new social security law gave the health insurance funds a clear preponderance over their former partners. The funds were designated as carriers and the physicians as performing aids. The physicians made contracts with the insurance funds, but they also had to carry all the burdens of a free profession. They had to equip their offices and pay rent on them, but they did not participate in the 48 hour week, overtime pay, paid vacation, or old age pension plans. They were, however, bound by regulations of the insurance funds the same way the workers were. Their fees, which had remained far below the costs of living, were fixed by the insurance funds. Only the amount that remained after all the cost of sickness benefits, hospital expenses, administration, and drugs had been met was allocated for the physicians' fees. In 1949, when the physician's

law gave the physicians legal representation, the economic position of the profession improved but some of the regulations of the social security law became a permanent drag and had to be fought constantly. In 1955 a revision, the ASVG, was drafted. It was this law that became the center of the conflict.

Provisions of the New Social Security Bill.—All employees, white-collar workers and laborers alike, are required to participate in the insurance. The compulsory funds are divided into the regional health insurance funds, an agricultural health insurance fund, a health insurance fund of the federal employees, a health insurance fund of the federal railroads, a small number of health insurance funds for certain larger industries or for the employees of the city of Vienna, health insurance funds for self-employed persons, the so-called master health insurance funds of general trades, and some small health insurance funds such as those of lawyers and public notaries. The statutes of these compulsory funds give in addition a free margin for a voluntary insurance, particularly in the form of a voluntary continuation after employment has been discontinued, but they also comprise automatically all the members of the family of the insured persons.

Voluntary health insurance funds exist in Austria but are of little importance compared with the comprehensive compulsory funds. These voluntary funds are appreciated by the insured persons and by the physicians. Their most important functions are to provide benefits in addition to medical treatment (including specialists), complete hospitalization for 26 to 52 weeks, transportation to the hospital, drugs prescribed by a physician, obstetric service, pregnancy benefits, and nursing and dental care (the patient pays part of the cost of prostheses) provided by the compulsory health insurance funds. Since compulsory insurance embraces nearly the entire population, there is little room for any private practice. The management of the compulsory insurance funds is in the hands of two committees, but the physicians have neither a seat nor a vote in these administrative bodies. This exclusion of the physician from the management of the insurance funds was associated with an appalling reduction of fees. A small number of physicians in administrative or industrial positions are paid a fixed salary, but the overwhelming majority work as contract physicians and are paid according to individual contracts, which are drawn up according to regulations of fees that differ regionally and according to the various health insurance funds. From the original concept of granting treatment at reduced rates to those who are needy, now the reduced rates apply to everyone. The system's disadvantage is that the physician is exploited, the insured person fears he will not be well taken care of, and administrators of insurance funds assume that the physicians are collecting insurance certificates (as a basis for their fees) and are admitting too many patients to hospitals, although neither of these assumptions has been confirmed.

Amount of Fees.—The amount of the fee varies greatly. In 1955, the master sickness insurance funds and the insurance associations of the federal employees and federal railroads paid about 25 cents for a consultation and twice that for home calls. The funds with lump sum contracts pay fixed amounts per year or a percentage of the fund's revenues. Funds granting a lump sum for the individual case pay only $0.77 to $1.15 per case for services including consultations, home calls, and injections for each three months. On behalf of the Main Combine, the director stated in a radio broadcast that each contract physician earns $230 on the average per month. He based this statement on the yearly amount of physicians' fees, totaling $16,795,480, but this figure includes all the fixed salaries of administrative and industrial physicians, which amount to about 20% of the total figure. The Chamber of Physicians estimated that the average monthly income of the contract physicians was $173. This includes payments for such items as major operations, refunds for travel expenses, supplies, office rent, and x-ray examinations. In other words it represents receipts, not income. According to the yearly report of the Lower Austrian Regional Health Insurance Funds, 17 physicians had a gross income of less than $38.50 a month; 216 received $63.50; 171 received less than $115; and only 164 received more than $192. Furthermore, no health insurance funds pay a penny to the physician if he becomes disabled by an infectious disease acquired in the line of duty.

About 2,250,000 insurance certificates were submitted by the 680 contract physicians of Lower Austria in 1952, or about 275 per month per physician. Each of these certificates represented about six office calls, counting one home call as two office calls. Thus 1,650 office calls fall to one physician's share in one month. If the contract physician received (as the director asserted) $230 a month, he would be paid about 14 cents gross income for one office call, including all expenses, night service, overtime and Sunday work, and return on his expensive education, but in reality he receives only about 10.5 cents. In spite of all this, the patients are receiving good care. The physicians' services are highly appreciated by everybody. This should make it clear that the situation of the Austrian physicians, as it was bound by the Social Security Transition Law, was highly unsatisfactory. The physicians believed in social security as such, but they believed that a new code was necessary and looked forward to its enactment.

Objections to Proposed Social Security Law.—Since 1953, when the outline of the social security law that was worked out by the Main Combine and by the Ministry of Social Service became known, the Chamber of Physicians objected to some of the regulations and presented an alternate plan rewording the part of the law that dealt with the regulations concerning the relationship of the physicians with the insurance carriers. After long, difficult negotiations with the Main Combine, the political parties, and finally the Social Committee of the National Council (parliament), in the summer of 1955 an agreement seemed likely. The main points against which the physicians fought were further extension of the compulsory insurance, without collecting higher fees from the insured persons in the upper income brackets or without granting higher fees to the physicians, and further unlimited construction of ambulatoriums, without granting the physicians the right to determine the needs for such ambulatoriums and without maintaining the competition between contract physician and ambulatorium under equal conditions. The main points for which they fought were the right of work for every physician in the frame of the social security, since nearly the entire population already is included; protection against arbitrary notice given to the contract physician without stating reasons; an objective, independent group of appeal judges with the right to make decisions; and the establishment of more equitable fees.

The proposal of the Chamber of Physicians was based on the following principles of the World Medical Association: free selection of physician by the patient, no intervention by a third party between physician and patient, control of medical service only by the physician, free selection of hospital, freedom of movement for the physician, freedom of administration of drugs and treatment, representation of the medical profession in public agencies for medical care, free professional activities of physicians, payment independent of the financial situation of the insurance funds, admission of all physicians to social security benefits, no compulsory insurance of persons who are able to pay for their medical care, and no exploitation of physicians.

With infinite patience an attempt was made to have these basic claims presented in the social security law, but, because a satisfactory result could not be obtained by the negotiations with the Main Combine, the large-scale protest of June 18 was staged. Its success was overwhelming. There was general agreement among the Austrian physicians, independent of party membership, medical specialty, or age. A resolution was presented to the Federal Chancellor, and as a result conferences were held and differences seemed to be resolved. In August, the cabinet formally introduced the social security bill in the National Council. It did not contain any of the improvements that had been agreed on with the physicians. A warning strike was staged throughout Austria on Aug. 25 and 26. This was carried out without any disadvantage to the patients. The population sided with the physicians as did the press, because this was not a common strike about wages only but in the final analysis about the question of monopoly and collectivism on one side and the individual and his freedom on the other.

CUBA

Brain Tumor in Children.—The anatomic and topographic characteristics of 80 children under the age of 15 years affected with brain tumor have been analyzed by Dr. Jorge A. Picaza and his co-workers (*Revista cubana de pediatría,* vol. 27, no. 6, 1955). The patients were divided into three groups: group one consisted of 29 patients who had a malignant tumor proved histologically and whose prognosis was hopeless; group two consisted of 29 patients who had a histologically benign lesion but one which by virtue of its location (basal-nuclei, pons, optic chiasm, or third or fourth ventricle) could not be removed surgically without great risk; and group three consisted of 22 patients with a histologically benign lesion located in a more accessible site. In a follow-up of one to four years only four patients in group one were still alive. Of those in group two, 3 were alive and well; 4 reported an improvement of symptoms after radiotherapy (this is usually ineffective); 4 could not be traced; and 18 were dead. Mortality in patients of the type classified as group three is conditioned by such factors as the size and depth of the lesion, the patient's general condition, and the surgeon's skill. Fifteen patients in group three were cured by removal of their tumor; two were improved for a short time only; and the remaining five were dead. Only about 25% of the children with a primary neoplasm of the brain can be cured by the forms of treatment now available. Surgical removal is the only treatment capable of resulting in a permanent cure. Radiotherapy gives temporary relief in some patients. In evaluating the therapeutic results in children with brain tumors, the public, and even the average physician, tends to overemphasize the operative mortality and to overlook the fact that the long-term results are better than those usually observed in the treatment of other neoplasms in children.

Artificial Hibernation for Cerebral Vascular Accidents.—Dr. Centurión and his co-workers (*Archivos del hospital universitario,* vol. 6, no. 6) have treated five patients with cerebral vascular accidents with artificial hibernation. This treatment lessens the metabolic requirements of the body, prevents hyperthermia, permits normal respiratory rhythm and control of bronchial secretions, stabilizes arterial pressure, and allows adequate cerebral circulation. Four of the patients so treated (three with cerebral hemorrhage and one with cerebral thrombosis) were cured, and one with hemorrhage died.

ENGLAND

Food Poisoning.—About two-thirds of the outbreaks of food poisoning in Great Britain are due to eating such meat preparations as sausages, meat pies, and ground meat. Salmonella organisms are responsible for many outbreaks, but there is always some doubt as to whether the organisms are already in the food or are transmitted to it by food handlers. A recent outbreak of food poisoning in Lancashire (Reports on Public Health and Medical Subjects, no. 96, London, Her Majesty's Stationery Office, 1955) involved 1,149 persons of all ages, 5 of whom died. The infected food proved to be meat pies from a bakery, the causative organism being Salmonella morbificans, which is relatively uncommon in Britain. This organism was found in the feces of most of the sufferers and in a large proportion of the pies. Most patients were bacteriologically clear by the 4th week, but five were still carrying the organism after the 15th week, even though they had all been treated with antibiotics and sulfonamides. Examination of the bakery staff, the common constituents of the pies, such as gelatin, flour, and fat, and the cooking utensils yielded no trace of the infecting organism. It was, therefore, assumed to come from the meat, some of which had been kept for eight days before delivery to the bakery. A herd from which some of the meat was derived was found to be infected with S. morbificans. Whatever the source of the organisms, these would have been killed if the pies had been properly processed. Tests showed that a temperature of 380 F for 40 minutes is lethal to Salmonella in a 4 oz. pie. This temperature was not reached in the oven in which the pies were cooked. The baker's choice must have been between damage to his pies or to his customers. Experiments were made to see if pies could be contaminated after baking. Organisms could be recovered from the pies if the operator's fingers were contaminated. A bowl of gelatin used in making the pies was found to be a yard away from a dirty wash basin, and an operator preparing the gelatin was found to be a symptomless carrier of Salmonella typhimurium. Meat pies are a popular and cheap article of food in Great Britain, and, as the incidence of Salmonella poisoning is rising every year, great care should be taken in food processing to use temperatures that sterilize cooked foods and to insist on scrupulous cleanliness on the part of the food handlers before and after cooking.

Safer Anesthetic Apparatus.—A new safety device to prevent mistakes in administering the wrong anesthetic gas has been announced by the British Standards Institution. At present each gas cylinder is clearly labeled by name and is distinctively colored to identify it. Large cylinders, such as are used for pipeline installations, have valves of a type that make it impossible to connect them incorrectly. The British Standards Institution has announced the adoption of a noninterchangeable valve for gas cylinders, with a capacity of 24 cu. ft. or less. Several medical men, including representatives of the Association of Anesthetists of Great Britain and the Medical Defence Union, have been serving on the British Standards committee dealing with the problem. The principle of the noninterchangeable valve is similar to that of radio valves, whereby spacing of the pins insures that each type can be inserted only in the corresponding socket. Differently spaced pairs of holes in the valves correspond with pins in the connecting part of the administration apparatus, so that only the right cylinder can be connected to the right yoke. It will thus be quite impossible to connect a cylinder of carbon dioxide or nitrous oxide to an apparatus administering oxygen. Deaths from this kind of error have occurred in the past. An identical valve system is already in use in the United States, Canada, Australia, and Switzerland, and it is hoped that all NATO countries will adopt it so that the medical services of their armed forces can be coordinated. The system has also been recommended in Stockholm by the technical committee of the International Organization for Standardization. The new equipment will be available in Great Britain in the fall, but the conversion of existing apparatus will not start until the fall of 1956 as new tools are needed. The first machines to be converted will be those in hospitals. Manufacturers will bear the cost of converting gas cylinders, but the cost of converting apparatus will be the responsibility of the owner.

International Congress on Diabetes.—The second Congress of the International Diabetes Federation met in Cambridge in July. The Banting Lecture of the British Diabetic Association was given by Dr. Joslin of Boston, who all his life has advocated strict control of diabetes to prevent or delay complications. His views are supported by data on the longevity of diabetic patients and their causes of death. Prof. F. G. Young of Cambridge reported that he was able to produce all the signs and symptoms of metahypophysial diabetes, except the changes in nitrogen balance, by injecting the growth hormone into dogs. The diabetes may persist after stopping the injections. Professor Tunbridge, who has treated 400 diabetic patients with the new insulins, listed the following disadvantages: they frequently block the needle; antiseptics reduce their activity; they are not useful in treating hypoglycemic states; there is difficulty in changing to them from other insulins; and they may produce cumulative action. The general opinion was that the insulin-zinc suspensions were unsuitable for unstable diabetic patients and that the difficulties mentioned made them unsuitable for most other patients with diabetes. In the discussion Dr. Joslin said that if a patient were doing well on any type of insulin he should not be changed to another.

Dr. M. Stahmann described work done in the United States to show that synthetic polypeptides, such as polylysine, could prolong the action of insulin without appreciably delaying its initial action. Somewhat revolutionary views on the nature of glucagon were put forward by Prof. G. E. Anderson of Brooklyn, who proposed that this was the trigger for the release of insulin in the postabsorptive state. Although it had itself a hyperglycemic effect, it potentiated the hypoglycemic action of insulin. Dr. Butterfield of Guy's Hospital, London, stated that dimercaprol improves the glucose metabolism in patients requiring large doses of insulin and in patients with burns but that it was to be regarded at present as a research tool and not as a therapeutic agent. It probably acts on the sulfhydryl groups in insulin. Dr. Oakley of King's College Hospital, London, stressed that not only arterial lesions but also neuropathy was responsible for diabetic lesions of the foot. He recommended conservative treatment, but if amputation must be performed it should be below the knee. Papers were read on hypophysectomy for severe diabetes by Dr. L. W. Kinsell of Oakland, Calif., and Dr. R. Luft of Stockholm, Sweden. This rather drastic treatment was limited to young diabetic patients with retinopathy and progressive vascular and renal disease. The hypophysectomized patient became more sensitive to insulin, and reversion of some of the diabetic complications occurred. If the patient could not maintain a normal blood urea nitrogen on an intake of 50 gm. of protein daily, the operation was contraindicated. Dr. J. C. Garbino of Uruguay reported the symptomatic improvement of diabetic retinopathy by the local application to the eye of a solution containing the pituitary melanotropic hormone.

Applied Bacteriology.—The Society for Applied Bacteriology held its first international symposium at Cambridge in July. Dr. K. W. Newell and his co-workers of the Central Public Health Laboratory, Colindale, London, described six outbreaks of Salmonella schottmülleri infection occurring in London, Windsor, and Basingstoke last year. Infection was traced to frozen eggs from China used as a cream filler in a London bakery. They were heavily infected with different Salmonella types. Dr. Newell favored pasteurization of all egg products. Dr. R. M. Fry and Dr. J. Boissard of the Public Health Laboratory, Cambridge, described an explosive outbreak of sore throat affecting 29 soldiers 36 hours after eating a meal. Infection was traced to custard prepared by a cook with a bad cough. It was shown that the streptococci isolated from the cook and responsible for the infection could survive on the skin of the custard. Eight outbreaks of micrococcic (staphylococcic) food poisoning affecting school children were investigated by Dr. Hobbs of Colindale. The vehicle of infection was mock cream prepared from spray-dried milk, which had become infected from human sources after heat treatment. Dr. W. Wilson of the Public Health Laboratory, Melbourne, reported an outbreak of typhoid due to phage type E1. The cases were widely scattered and not connected with known carriers in Australia. One of the victims of the outbreak was taken ill with food poisoning due to Salmonella senftenberg and subsequently was found to have typhoid. Careful investigation showed desiccated coconut imported from Papua to be the source of the infection. The authorities in Papua have now put a stop to production.

The largest outbreak of food poisoning due to Salmonella typhimurium yet recorded was described by Prof. H. Lundbäck of the Stockholm State Bacteriological Laboratory. Affecting 8,845 people, of whom 90 died, this outbreak was due to a strike of slaughterhouse attendants. The living quarters of the animals in the abattoir became overcrowded, and the infection was only controlled by closing the abattoir, cleaning it, destroying all carcasses, and segregating infected persons. One remedy would appear to be smaller slaughterhouses. Dr. M. Ingram and Miss E. Barnes of the Low Temperature Station, Cambridge, suggested the possible use of the broad-spectrum antibiotics for the preparation of meat. They could be used in animal feeds, injected before slaughtering, or incorporated in the processed meat. In the United States, however, such treatment is not acceptable, as antibiotics cannot be used in foodstuffs. An unusual case of food poisoning due to Bacillus cereus affecting 600 people was described by Prof. S. Hauge of Oslo. The main symptoms were abdominal pain, watery diarrhea, and nausea. The organism, isolated from flour, produced similar symptoms in volunteers.

Medical Research Council Annual Report.—In the report of the Medical Research Council for 1953-1954 (London, Her Majesty's Stationery Office, Cmd. 9506, 1955), Prof. J. S. Mitchell of Cambridge reports that a water-soluble vitamin K analogue is taken up preferentially by tumor cells and makes them more sensitive to radiotherapy. The mean survival time in 46 patients with inoperable lung cancer was only four months after radiotherapy. After injection of the vitamin K analogue at the time of radiotherapy the survival time in a comparable series was three times as long. Radioactivity damages living tissue largely because it breaks up water molecules. The best protection against this, so far, is cysteine, which will double radiation tolerance. Another protection against radiation is the injecting of normal splenic cells or bone marrow cells just after exposure. This increases survival after lethal doses of radiation.

Expletives in Dentist's Chair.—A female dentist who declined to treat a patient further because of his persistent use of objectionable language while having a tooth drilled by an assistant was ruled by the Middlesex Health Executive Council to have failed technically to comply with the terms of service. The council recommended that she should not receive the patient's contribution of $2.80. The patient said that when the drill touched a nerve he jumped up, waiting for the pain to subside. The dentist entered and asked him to leave immediately and cancel further appointments. After discussion the filling was completed. The patient denied using obscene language but said that he might have used a few mild expletives. Finding the dentist technically in breach by not requesting permission to withdraw from the case, the council commented: "The expressions used by the patient might have been his usual mode of speech. This case centers on differences of opinion between two contrasting temperaments."

Doctor Not to Pay Fine.—The workings of the National Health Service are illustrated by the following item. The Ministry of Health has informed the London Executive Council that the minister cannot direct the withholding of $85 from a physician as recommended by the council. The physician failed to comply with the terms of service about inspection of his premises and refused to accept notices about a meeting of the medical service committee inquiring into the case. The ministry wrote to the council saying: "It does not appear to the Minister clear that there has been a breach of the terms of service in that the respondent did not actually refuse admission to inspect his premises." The minister thought that there should be a further attempt to make an inspection. A failure by the physician to make arrangements for admission might constitute a refusal to permit inspection.

Physicians' Lists Inflated.—Lieutenant Colonel Lipton (socialist) asserted that the number of patients on National Health Service physicians' lists in the London area exceeded the population of London. He asked for a check of the records and less waste in paying capitation fees to physicians. The Minister of Health said that the number of patients on physicians' lists in London are not in excess of, but closely approximated, the total population and that there was a good deal of inflation in these lists. This does not affect the cost to the Exchequer, but he will review the lists anyway.

Incidence of Poliomyelitis.—Cases of acute poliomyelitis in England and Wales numbered 177 in the week ended July 23, according to the Registrar General, compared with 120 in the previous week and 99 in the week ended July 9. In the week ended July 22, 1954, there were 91 cases. On July 22 this year, 55 patients with poliomyelitis were admitted to Neasden Isolation Hospital on one day. Only one had the paralytic form. A spokesman of the Central Middlesex Hospital Group said: "We are not unduly alarmed. Measles is tapering off and poliomyelitis coming in; it is a seasonal increase."

Death from Barbiturate.—A pathologist said at a Birmingham inquest that a woman's death was caused by a sedative she was given at a mental hospital and that the treatment, although a recognized one, was dangerous. The psychiatric resident at the hospital said that the patient was kept in continuous narcosis. The treatment, involving in her case a dose of 0.5 gm. of a barbiturate, was admittedly dangerous but is one of the oldest treatments used in psychiatry.

Medical Records Exhibition.—The first Medical Records Exhibition was held in London in May by the Association of Medical Records Officers. It illustrated current methods of keeping and storing records and of marshaling patients. At Woolwich Memorial Hospital the whole of a patient's clinical record is photographed. At University College Hospital, microfilming has been resorted to, radiographs included. Existing storage space can also be made to hold more folders by using mobile stacks of shelving to reduce the circulating area required in the record store or lateral filing to increase the number of levels of shelving between floor and ceiling. At the Edgware General Hospital the outpatient cards are kept apart from the inpatient records and destroyed after 7 years; the inpatient notes are bound after one year and destroyed after 20 to 25 years, with the exception of summary sheets, a system that demands a high standard of summary writing. Surveys indicate that no patients return for the same condition after 15 years. Sound-recording facilities exhibited from the Hospital for Sick Children showed that dictation can now be recorded on disk machines in the typing room. Devices such as visible card trays have been found to ease the task of selection and control of waiting lists. A public health records exhibit featured a continuous health record kept from the antenatal period until school-leaving age. The Farnborough Hospital exhibit included a nightly ward return which served not only as a basis for bed statistics but contained a forecast of patient movements in the next 24 hours, this being used as a guide in dealing with applications for emergency admission. The value of graphs in the improved use of hospital accommodation was stressed on the King's College Hospital stand.

Epidemiologist.—In the *British Medical Journal* of July 30 J. R. W. Hay says that the epidemiologist has contributed much to the reduction of illness and its cost to the community. Cholera, typhus, typhoid, and diphtheria have been practically eradicated in this country. Curative measures account for about 95% of the Treasury's contribution to the National Health Service, the rising cost of which is a matter for increasing concern. A savings could be made if scarlet fever were no longer treated in an isolation hospital, except for occasional cases. Furthermore, the present undue emphasis on hospital midwifery seems to be a costly and possibly unhealthy trend. Although many obstetricians advocate hospital for most if not all confinements, all that the epidemiologist can say is that the risk of infection to both mother and child is much higher in the average hospital than in the average home. The empirical use of antibiotics before the organism causing the patient's illness is identified is another harmful and expensive practice, and mass miniature radiography can now be safely dispensed with, provided other diagnostic facilities, including small film apparatus, are adequate. The author would concentrate on vaccinating the school child with BCG to eradicate tuberculosis.

Doctor at Sea.—The young man who passed his exams so entertainingly in "Doctor in the House" now becomes a ship surgeon in the film version of Richard Gordon's "Doctor at Sea." Fleeing the ardent embraces of his principal's daughter, the tyro general practitioner gets a post on a small ship sailing to South America. An eccentric crew, the diffident doctor, and medical comforts provide clean fun aboard ship, while the South American port gives plenty of scope for showing that the improper study of mankind is woman. Here we meet the delightful Brigitte Bardot, a new French star, and Dirk Bogarde as the young physician is what every layman thinks a young physician should be. James Robertson Justice roars with convincing aplomb as the irascible captain of the ship. Romance, humor, and the discovery that some aspects of the practice of medicine are not in the textbooks combine here to give us a tonic with no trace of a bitter taste.

More Calories Consumed.—People in Britain last year used more butter, fat, eggs, sugar, syrups, fruit, cheese, meat, bacon, canned fish, tea, and cocoa than they did in 1953 but less milk, fish, poultry, flour, and vegetables. Provisional figures published in the *Board of Trade Journal* show that food eaten in 1954 represented an average per capita consumption of 3,120 calories a day, as compared with 3,000 calories in 1953, 2,950 in 1952, and 3,000 before the war.

Needless Dosing of Infants.—The *British Medical Journal* of July 16 includes a report by Dr. R. D. G. Creery on the questioning of the mothers of 200 children, aged 6 months to 3 years, who attended the Royal Belfast Hospital for Sick Children for BCG vaccination. Although apparently normal, 184 of these children had been given alkaline mixtures at some time. Magnesia had been given to 158, generally for the regulation of the bowels, and 133 had received carminatives, usually for "wind." Both magnesia and carminatives had been given to 107. The author believes that, although not actively harmful, the habit of dosing infants with alkalies is meddlesome and unnecessary and should be discouraged. These medicaments are not inexpensive and are often given for symptoms that exist only in the imagination of the mother. That their infants should defecate daily with absolute regularity amounts to an obsession with many mothers and seems to determine the frequent resort to magnesia. The crying fretfulness so often put down to flatulence may well be due to unsatisfied hunger for which carminatives are a poor remedy. One of the most popular of these mixtures contains about 4% of ethyl alcohol, a concentration not far below that of some brands of beer, stout, and cider.

Drug Used to Gain Courage.—The hope that the authorities would place Oblivon (Methyl Pentynol), known in the United States as Dormison, on the dangerous drug list was expressed by Justice Byrne, after he had been told that it could be purchased without a prescription. Two youths took Oblivon tablets to gain sufficient courage to burglarize a house at Ramsgate. After the burglary they stole a motorcycle and were involved in a crash in which one of them was killed. The surviving youth pleaded guilty to driving a motorcycle while under the influence of a drug, reckless driving, burglary, and theft. The prosecutor said that the two youths had bought 25 Oblivon tablets from a druggist. Although the normal dose is one or two tablets, the surviving youth had taken eight tablets in 24 hours. The effect was startling. When he broke into the house he had no sense of fear, and when he took the motorcycle, although he did not know how to drive, he had no sense of danger. The Poisons Board has now recommended that Oblivon should be classed as a poison, which may be sold only to persons known to the druggist, on a medical prescription, or on a police order, and that the purchaser must sign the poisons register.

Children in Hospital.—To reduce anxiety and help parents understand hospital regulations, the Central Middlesex Hospital gives a printed pamphlet to parents of children admitted. The pamphlet describes in simple terms the emotions of the child who is left in the hospital, and it makes some helpful suggestions. Daily visits are encouraged in order to increase the child's sense of security while in the hospital and to facilitate his readjustment when he returns home. These visits are restricted to parents who are advised not to promise to take the child home every time they see him but to tell him instead that he can come home as soon as he is better and that this is for the doctor to decide. Gifts of food are discouraged and, if candy is brought, it should be handed to the nurse who will pool all such gifts and share them equally among all the children on the ward after their meals. The pamphlet concludes: "Please don't listen to what your friends, neighbors, relatives, or other parents have to say about your child's illness. If you want to know how he is getting on, ask the nurse, and if necessary, she can arrange for you to see the doctor."

Blood Donors.—Blood donations to hospitals in England and Wales through the National Blood Transfusion Service in 1954 were higher than ever before. Last year 104,161 people gave blood for the first time, and by the end of December the total strength of the donors' panel was 540,389, an increase of nearly 25,000 as compared with 1953. To insure that no one need be asked to give blood more than twice a year, the National Blood Transfusion Service needs 650,000 regular volunteer donors.

Faith Healing.—The crowded chapel with the unscreened public in a state of mass hysteria is not the right atmosphere for spiritual healing, according to Dr. Weatherhead, president of the Methodist Conference, which convened in Manchester. Even though everything is done to exclude unhealthy emotionalism, it is almost always there, just below the surface. In such a situation, temporary cures are easy and are widely publicized, whereas the subsequent relapse gets little or no publicity. Few experiences, however, can be more bitter to the patient, because he is led to believe that the relapse is caused by a loss of faith, or he may conclude that religion is no good, when the truth may well be that he has mistaken suggestibility for faith and has tried to take a short cut in the treatment of a hysterical illness. Many people have foolishly delayed medical, surgical, or psychiatric treatment, waiting for the visit of some healer who is here today and gone tomorrow.

MEXICO

Symposium on Obesity.—At the symposium on obesity held in Mexico City in July, Dr. S. Aceves of Mexico City said that obesity is produced by hyperalimentation in 95% of the cases. Extreme obesity may produce fatty infiltration and diminished contractility of the myocardium with consequent coronary insufficiency or heart failure. Increased body weight increases the work of the heart. An increased coronary supply is demanded to meet the requirements, but obesity predisposes to coronary disease. In a group of 80 soldiers between the ages of 20 and 36 years who died from coronary disease, 72 were overweight. Obese patients are predisposed to sudden death from pulmonary embolism or fatty infiltration of the myocardium. The grave complications of arteriosclerosis (coronary occlusion and cerebral thrombosis) are frequent in the obese because the arterial lesions are acute from the start. In the obese patient with cardiovascular disease, a diet poor in fat and in cholesterol, administered for an indefinite period, would be beneficial, but such a regimen is impractical. Heparin should be given.

Dr. R. H. Haddad of the Mexican General Hospital said that every gram of extra fat in the obese patient calls for an added kilogram of circulation. When such a patient must be operated on, preoperative reduction of weight should be vigorously attempted. Spinal anesthesia is preferred except in patients with a systolic pressure below 100 mm. Hg, a spinal disease, or extreme nervousness. The tissues should be handled gently, perfect hemostasis maintained, and as little foreign material as possible introduced. Touching of the venous plexuses is avoided if possible. Early ambulation should be encouraged.

Adiposogenital Dystrophy.—Dr. J. Chávez Montes of the National Faculty of Medicine stated that the short stature of patients with adiposogenital dystrophy (Froehlich's syndrome) seems to be due to deficient secretion of thyroid and gonadal growth hormones. In the case of Simpson's adiposo-adreno-genital-hypophysial syndrome, which occurs exclusively in young boys, the stature may be either normal or supernormal but with eunuchoid proportions. Morgagni-Stewart-Morel's and Laurence-Moon-Biedl's syndromes are usually associated with dwarfism and hypogonadism. Pituitary basophilism, adrenal cortical hyperfunction, and the Achard-Thiers's syndrome are characterized by corticosuprarenal adiposity, mainly of the head, neck, and trunk. These diseases, appear in adults of normal stature. The adiposity is correctable by means of a proper diet. Bearded diabetic women may be either dwarfed or of normal stature. In patients with congenital athyreosis, thyroid extract causes improvement of the excessive weight, short stature, and retarded mental and physical development. A moderate degree of hyperinsulinism from pancreatic disorders can be the origin of an exaggerated adiposity and of diabetes mellitus. Gonadal obesity is characterized by accentuation of the fat distribution normal to each sex. The tendency to gain weight in the menopause is related to constitutional factors and not to gonadal activity.

Modification of Diet.—Dr. J. Q. Olascoaga of the National Institute of Nutrition stated that in obese children and young people the diet they are receiving when they are first seen in consultation should be continued because they are still growing. Only in rare cases is the diet modified, and then a minimum of 80% of the caloric needs of the patient should be given without reducing the protein, vitamin, or mineral intake. Obese adults may be given diets containing 30 to 60% of their caloric requirements provided liberal quantities of fresh milk; lean fresh meat; eggs; fresh fruits; fresh, uncooked, unsalted vegetables; and preserved fruits are given. Reducing diets should be adjusted in accordance with the age, work, climate, and economic condition of the patient. The sodium intake should be decreased and the potassium intake increased in obese patients with edema. Dr. S. Maynez Puente of the same institute said that in spite of the fact that the caloric value of normal diets has decreased since 1900, obesity has increased. This can be explained in part by the increase in life span, with consequent increase of the proportionate population in the older age group. Obesity is caused by an endocrine dysfunction in only 50% of the cases and by overeating in the rest. Toxicoses of pregnancy develop in 75% of obese women who are pregnant and in only 20% of those whose weight is normal.

SWEDEN

Mental Hygiene Reform.—In a memorandum to the Swedish government and to university, municipal, and other local authorities, the Swedish Medical Association and the Swedish Psychiatric Society have severely criticized the present state of affairs in the field of mental hygiene and have outlined an ambitious scheme for its reform. Even before the adoption of national health insurance at the beginning of 1955, the hospital and other social services were so effective that no one suffering from serious somatic disease had to fear neglect. It has been otherwise with mental disease. A large number of patients of the mental hospital are human beings whose diseases have become chronic because of defective welfare resources. Even those greatly in need of care cannot be accommodated, and frequently those who can be admitted cannot be treated adequately. Of a total of between 5,000 and 6,000 members of the medical profession, only about 400 are in the field of mental hygiene. Of these, 300 are employed in mental hospitals run by the state, municipal authorities, or psychiatric departments of general hospitals. Even at the cost of extending the medical curriculum by another month or two, provision must be made for more training in this particular field. The rate of remuneration for private practice in psychiatry must be raised. Research in psychiatry must be fostered. The memorandum is published in full in *Svenska läkartidningen* for July 22.

National Health Insurance.—At a meeting in May of the Jämtland County Medical Society, the working of the national health insurance scheme initiated at the beginning of this year was reviewed by a senior hospital surgeon, a district medical officer, and a private practitioner. All agreed that the clerical work, such as that entailed by the filling in of forms, had increased the day's work by about 10% at the expense of the medical care of the patient. As a result some overworked physicians now send more patients to the hospital for examination and treatment than formerly, and this means an additional burden for the hospital staff and an increase of the list of those awaiting admission. According to one calculation, the interval between application and admission has been increased by 25 to 33%. Care of the seriously ill patient is apt to be interfered with by a growing demand for the treatment of such minor ailments as birthmarks. Furthermore physicians are expected to decide whether a patient should get to the hospital by taxicab or by bus. Hospital laboratory work, already overburdened, has approached the breaking-point under present conditions. Various readjustments in the machinery of the scheme were called for, chiefly with a view to simplification of the clerical work imposed on the medical profession. The discussion is reported in *Svenska läkartidningen* for July 22, 1955.

Poliomyelitis.—Lindström and Grenhagen, in *Svenska läkartidningen* for July 15, reported that certain areas of Stockholm relatively free from poliomyelitis in 1953 were connected with beaches liable to pollution by sewage. On these beaches children could play and conceivably develop immunity to poliomyelitis. The authors of this study emphasize the quite tentative character of their findings, and they admit that its value is limited by the facts that they have dealt only with the city of Stockholm and that their investigation was limited to only one year. In *Nordisk medicin* for July 14, H. Dagulf draws attention to differences in the incidence of poliomyelitis as it has affected the city of Stockholm or its suburbs. In the former there were only 66 cases per 100,000 inhabitants, whereas the corresponding figure was 179 in the latter. The difference might to some extent be due to the number of children in the former being comparatively low, but this does not explain why the morbidity rate among adults was twice as high in the suburbs as in the center of the city. Another remarkable phenomenon was the upward shift of the adult age group affected. Between 1911 and 1913, 82% of all the cases concerned the age group from birth to 15 years. In 1953 the corresponding percentage was down to 47, and the ratio of adult to child victims quadrupled. About 60% of all the cases were paralytic, and the case fatality rate was 3%. The incidence of paralysis was higher among adults than among children, being 65 and 57% respectively. Multiple cases in households were recorded at 19.5%, with 176 cases in 80 families.

SWITZERLAND

Swiss Hospital Service.—There are 535 hospitals in Switzerland for a population of 4,500,000. The university cities of Basel, Bern, Zurich, Lausanne, and Geneva are clinical centers with all the specialties. They serve areas exceeding the boundaries of their respective cantons. Next to them, in order of their importance, are the cantonal hospitals of Aarau, Lucerne, and St. Gall. The rest of the cantonal hospitals and district hospitals each have from 50 to 300 beds, and their importance is only local. The psychiatric establishments are almost all cantonal institutions having several hundred beds. The tuberculosis sanatoriums are located in regions chosen for their climate and have marked differences in size, legal status, and financing. The larger cantons have their own sanatoriums. The sanatoriums are located for the most part in Davos, Leysin, and Montana and have many foreign patients, chiefly French, German, Belgian, and English. In Switzerland the organization of a public health service is the responsibility of the canton or the commune; the federal government hardly participates at all in hospital activity —the two big federal insurance companies, the Swiss National Fund in Case of Accidents and the Federal Military Insurance, do not have their own establishments. The central government does, however, participate actively in the fight against tuberculosis by granting subsidies to antituberculosis insurance and by contributing to the costs of treatment. There are also a number of private hospitals, many of which are connected with a particular religion. The other establishments that function as private enterprises are dying out.

Diversity of Service.—The Swiss hospital service reflects the diversity of the Swiss Confederation. There is no central directing idea in it, owing to the absence of a central coordinating power. Switzerland has 74 beds for each 10,000 inhabitants. The canton of Basel-City heads the list with 148 beds per 10,000 persons. Even before the last war, population growth and the success of treatments undertaken in hospital had forced the hospitals to enlarge. For about 10 years, the hospitals have been in a stage of great expansion. About 100 enlargements and constructions of new buildings were approved between 1940 and 1954, and the necessary credits granted amounted to 500 million Swiss francs. Zurich heads the list with a credit of about 200 million. The shortage of beds is due, in Switzerland, in part to aging of the population. Hospitals keep a number of patients over long periods, in spite of advances in therapy that speed recovery, and often have to care for patients with chronic disease indefinitely. The creation of rest homes is being considered. These would be simpler in set-up and would take the pressure off the hospitals. The financial situation of Swiss hospitals is difficult. The total deficit of all the hospitals is estimated at 100 million Swiss francs yearly. The price of one day's hospitalization varies according to the class of the establishment. The university hospitals are the costliest because of their larger staffs and and the expenses of research and teaching. The daily cost there is about 30 francs, as compared with 20 to 25 francs in the larger cantonal hospitals. A ward patient is not in a position to pay such amounts, and insurance companies cannot afford more than 10 francs a day toward the cost of each patient. The average amount paid to the hospital a day from ward patients is between 10 and 15 francs each. This accounts for the deficit.

Hospital Expenses of Cantons.—Since the hospitals vary so from canton to canton, the expenses of each canton also vary. The university cantons have the highest expenses. The absence of a central plan leads to some injustices in the hospital system. The university cantons finance research and teaching; in other words, they pay for the training of physicians who practice in all the cantons, but in some of the larger cantons, namely Zurich, Bern, Vaud, and Neuchatel; an effort is being made at systematization. The cantons of Basel-City and Basel-Country are a splendid example of intercantonal cooperation. Basel-Country has given over its hospital care to Basel-City and in return is paying large subsidies to public and private hospitals. One of the most important problems that has yet to be solved nationally and in the individual cantons is rehabilitation. This is a social responsibility that has led to remarkable achievements with regard to disabled veterans in France, England, the United States, and Russia. In Switzerland, there is an impressive attempt at coordination in the fight against poliomyelitis. Thus the general tendency now is for the cantons and communes to assume the burden of the increased costs in hospitalization.

Another difficult problem is that of lack of hospital personnel, because the pay of hospital employees is low compared with that of other places of employment. The wave of Italian, German, and Austrian help that is flooding the entire Swiss economy has extended to hospitals. Despite increases in actual salaries, lack of personnel makes itself felt in hospitals, especially with regard to the nursing and domestic staffs. While the Swiss hospitals permanently employ 200 to 300 foreign nurses, mainly Germans, about twice as many Swiss nurses are working abroad, where they are highly prized because of their qualifications. In spite of a propaganda campaign and the modernism of schools of nursing, the number of girls entering nurses' training is smaller than it should be, even though the financial conditions have been bettered. Hospitals must function often with inadequately trained help—nurse's aids and auxiliary nurses —because of the shortage of nurses. The worst effect of the scarcity in hospital personnel is that it has been impossible to introduce the 54 hour week, in spite of the good will of those interested. It has been necessary to maintain the 60 hour week.

TURKEY

Placenta Previa Accreta.—In the *Bulletin of Istanbul University Medical Faculty* (vol. 14, no. 3) Erez and Arisan reported on two patients with placenta previa accreta. A 37-year-old primipara had a hemorrhage during her seventh month of pregnancy. Five, three, and two years prior to admission she had had induced abortions. Twenty-eight days after admission a severe hemorrhage occurred and a cesarean section was performed. The child was born alive. The placenta previa centralis adhered so closely to the uterine wall that it was impossible to find any line of cleavage for placental separation. Attempted separation resulted in laceration of the myometrial serosa, and a total hysterectomy was performed. In microscopic examination, extensive diffusion of villi was noted in the placental serosa. The second patient was 32 years old. Three years prior to admission she had a normal delivery. Five, four, and two years before admission she had abortions (two spontaneous and one induced). She was eight months' pregnant when the mild painless hemorrhage for which she was admitted occurred. She had a sudden severe hemorrhage 24 hours after admission, and cesarean section was performed. The child was born alive. Because the close adherence of the posterior and lateral segments of the placenta prevented manual separation, a total hysterectomy was performed. Microscopic examination revealed that masses of villi had invaded the placental tissue.

CORRESPONDENCE

AMPHETAMINE IN MANAGEMENT OF ORDINARY (SYDENHAM'S) CHOREA

To the Editor:—The purpose of this communication is to point out the effectiveness of amphetamine for the relief of overactivity, restlessness, and involuntary movement in ordinary (Sydenham's) chorea. Review of a number of articles on chorea reveals that this drug, which I have found helpful, has not received recognition for its usefulness in this connection. My attention was first drawn to the possibilities of amphetamine in ordinary chorea by my experience with the following case.

The patient was a 16-year-old girl with a chief complaint of uncontrollable movements. These had become increasingly more severe over a period of one month. During this period, the patient had also become increasingly more irritable. She was overemotional, overactive, unreasonable, and so difficult to manage that she was considered to be psychotic and admitted first to a psychiatric unit. The medical history included frequent attacks of tonsillitis, with three recurrences during the month prior to the onset of her chorea.

Examination revealed almost continuous choreiform movements of the face and extremities. There was generalized hypotonia, with pendular reflexes and "silver fork" posture of the hands. The heart was normal. The temperature was normal, blood cell count and urine normal. The sedimentation rate was slightly elevated (31 mm. per hour corrected).

During the first four days after admission, the patient was treated with phenobarbital, 512 mg. per day, and was kept isolated and with minimum stimulation. Throughout this period she continued to be irrational and extremely restless, there being no evident change in her condition. On the fifth day, amphetamine sulfate, 15 mg., was given in addition to phenobarbital, 512 mg. On the sixth day, because of a favorable response, the amphetamine dosage was increased to 30 mg. per day. This dosage was continued, and the phenobarbital dosage was gradually reduced to 96 mg. per day by the 10th day and its use was discontinued on the 16th day. The patient's response to amphetamine was striking. Within 24 hours of the first dose she became quieter and more reasonable. Her restlessness was reduced, although definite choreiform movements continued. The patient was permitted to go home on the 17th day and continued to take amphetamine for a month at home, experiencing a gradual reduction of her choreiform movements to normal. In this original patient, it was not clear to what extent improvement was due to withdrawal of barbiturates and to what extent to the result of amphetamine. However, an additional six patients have now been treated, and this additional experience suggests that in this condition amphetamine itself has a beneficial and quieting effect.

The following case is another example of severe ordinary chorea benefited by amphetamine. The patient was an 11-year-old girl who had had an attack of ordinary chorea three years previously. At that time, treatment with sedation over a period of five days did not bring about improvement. She was given a course of fever therapy (typhoid), and over a period of 10 days gradually improved. However, at the end of this time, she was still confined to a wheel chair and could not write her name. Two weeks later she continued to be overemotional and showed definite chorea. Three weeks later, she seemed entirely well. She was subsequently admitted to the pediatric service of Dr. Weston Kelsey with a recurrence of her chorea. At this time she had definite evidence of cardiac involvement. The temperature, blood cell count, and urine were normal. The sedimentation rate was moderately elevated (33 mm. per hour corrected).

At the time of admission, the patient was overemotional and restless. She exhibited constant violent choreiform movements. Her movements were so incoordinate as to make it impossible for her to feed herself. Her speech was almost unintelligible. On the first day after admission she received phenobarbital, 128 mg., with no change in her condition. The following day therapy with phenobarbital was stopped and she was given amphetamine, 10 mg. The following day she was strikingly improved. Feeding continued to be difficult, but the patient was now able to handle a fork, requiring assistance only with liquids. She was able to write fairly well. Her speech improved markedly. Whereas previously she was depressed, her attitude became cheerful and relaxed and she rested well at night. After striking improvement with this medication, the condition became stationary after about four days, and it was evident that the actual course of the disease had not been altered. However, by the end of 12 days, she was showing only moderate choreiform movement, being able to write, feed herself, and move about with little disability.

It must be recognized that ordinary chorea is a disease exhibiting a variable course. The possibility that spontaneous remission may occur at any time must be considered in evaluating any recommended therapy. However, experience with the use of amphetamine in these two reported cases and four other similar cases strongly suggests that the drug has an important place in treatment. It does not produce overactivity. On the contrary, it has seemed to reduce restlessness, irritability, and involuntary movement. It is particularly valuable as an aid in the management of mentally disturbed or psychotic patients.

CONTACT DERMATITIS DUE TO CHLORPROMAZINE IN A DENTIST

To the Editor:—Lewis and Sawicky (*J. A. M. A.* 157:909 [March 12] 1955) in a report on two cases of contact dermatitis due to chlorpromazine (Thorazine) in nurses handling it advise that because of its extensive use, the danger of sensitization on frequent or long-continued contact must be kept in mind by both physicians and nurses. Our patient, a dentist working with psychotic patients at a state institution, developed a dermatitis of the fingers that contacted the saliva of patients who had been and were under treatment with daily doses of chlorpromazine as high as 1,000 mg.

The patient was first seen July 27, 1955. Five days previously she had noticed a patch of dermatitis on the right hand. Within the next few days she had an erythematous, exudative, crusted eruption of the dorsal terminal phalanges of the second, third, and fourth digits of both hands, more severe on the left. The palmar aspects were not involved. She had been treating the teeth of mental patients who had been receiving massive doses of chlorpromazine. Undoubtedly the drug excreted in saliva and present in traces in those patients treated with it orally sensitized her. A patch test with an aqueous solution of chlorpromazine caused itching within five hours, and an area of erythema and edema appeared and persisted at the test site for several days. Her hands responded to appropriate therapy with grenz radiation in 10 days. She was able to return to work using a protective silicone cream (Kerodex 76).

According to Lewis and Sawicky, as reported by the pharmaceutical firm manufacturing Thorazine, patch testing of 50 individuals showed no irritation or sensitivity. However, in the testing, daily and prolonged exposure to it as in this case, and in nurses and physicians, was not considered. With the increasing use of chlorpromazine, individuals constantly handling it or coming in contact with drug-laden secretions of patients under chlorpromazine therapy should be aware of the possibility of epidermal sensitization and institute means to prevent or minimize contact with it.

RUBBER PROP FOR SYRINGE USED FOR INTRAVENOUSLY GIVEN ANESTHESIA

To the Editor:—Although many ways have been devised for the intravenous administration of anesthesia, the simplest method, the syringe and needle technique, remains very popular. Usually, a 20 cc. syringe is selected for the giving of the dilute barbiturate solution. A freely miscible muscle relaxant such as Syncurine may be included without complication of the method. A syringe prop is advantageous in two ways. If the hospital does not furnish eccentric-tip syringes, the prop, with the help of a few well-placed adhesive strips, will hold a regular syringe slanted at the right angle so that the needle tip remains securely placed within the lumen of the selected vein. With either the eccentric tip or a regular syringe, the prop makes the plunger most accessible to the fingers as the serial injections are given. It also facilitates manipulation of the tape used to restrain the plunger to prevent the backflow of blood.

An impromptu prop of gauze and adhesive tape is quite serviceable, but a special rubber one is even more satisfactory. This is easily made from a half of a rubber stopper measuring 2 in. across the top. Shaping is done in a vise by means of a knife and rasp and requires but a few minutes. This syringe prop fits and clings to the forearm. If it is fixed to the skin by a separate piece of 0.5 in. tape (see figure), the maneuver of switching syringes is made easy. When the rubber tubing of an intravenous drip set is punctured for the purpose of giving anesthesia, the prop assists in the technique. The prop is readily cleaned and will last for years.

THE DOCTORS FLINT

To the Editor:—A long medical dynasty has come to an end, and it would seem appropriate to publicly acknowledge medicine's debt to a famous family. On July 20, 1955, Dr. Austin Flint died in the Doctor's Hospital in New York City at the age of 87, having in his time been professor of obstetrics at Bellevue Hospital Medical College and later at New York University when these institutions amalgamated. He also had held several important consultant posts. A graduate of Phillips Academy, Andover, Mass., and of Bellevue Hospital Medical College, he also held an honorary master's degree, given him by Princeton in 1894.

Four physicians bore the name of Austin Flint. There were, in addition, other physicians in the family. The first Flint to study and practice medicine was Edward (1733-1818), who spent his life in Massachusetts. One of Edward's sons was the first Dr. Austin Flint (1760-1850), who witnessed the surrender of Burgoyne and took part in quelling the Shays Rebellion. He, too, spent most of his life in Massachusetts. As an example of his reputation as a physician he was granted, I am told, an honorary M.D. degree by Harvard. One of his sons, Dr. Joseph Henshaw Flint (1786-1846) was next in line and was also honored by Harvard in the same manner. Dr. Joseph's first-born was Austin (1812-1886), graduate of Harvard Medical School in 1833, co-founder of the Buffalo Medical College, founder of the *Buffalo Medical Journal*, and professor of medicine for brief periods at Rush, Louisville, and New Orleans. He spent the greater part of his professional life at Bellevue. It was this Austin who described the Austin Flint murmur and who wrote several celebrated textbooks. In addition to many other honors, he served as president of the New York Academy of Medicine, and in 1884 he was President of the American Medical Association. He was, indeed, one of the greatest of American physicians.

Austin III (1836-1915) graduated from Jefferson in 1857, became professor of physiology at Buffalo, and later assumed the same post at Bellevue. His textbook on physiology was a standard work for years, and he gained an international reputation in experimental physiology, particularly in studies on the urine and on muscle. His interest in the physiology of the brain led him to a high reputation as an alienist. Now his son Austin IV (1868-1955) has gone, and there is no direct descendant in medicine who bears the honorable name of Flint. There cannot be many families with six physicians in direct succession, and certainly there are few families that have done as much for American medicine.

ATARAKTOS

To the Editor:—In an interesting commentary (The Journal, Aug. 20, page 1461) Dr. Howard D. Fabing proposes the "tranquilizing agents," i. e., Rauwolfia serpentina, derivatives therefrom, chlorpromazine, and frenquel, be designated as ataraxics, the latter term being derived from the Greek word *ataraktos*, meaning freedom from confusion and peace of mind. It should be of interest to Dr. Fabing as well as readers of The Journal that some months ago the name Atarax was assigned to the compound 1-*p*-chlorobenzhydryl-4,2-(2-hydroxyethoxy)ethyldiethylenediamine hydrochloride by Dr. F. Martin, Union Chimique, Brussels, Belgium. Atarax, a close chemical relative of both Meclizine and Buclizine, is neither a good antihistaminic nor a good antiemetic agent as are the latter two compounds but has shown promise in Europe as a less toxic substitute for chlorpromazine.

RESEARCH ON MUSCULAR STRUCTURE AND FUNCTION

To the Editor:—Having opened a laboratory for the examination of muscles in Budapest in May, 1955, we would appreciate receiving reprints on muscular structure and function and related subjects from anyone engaged in this type of work. We are especially interested in the reactions of the body through functional changes in muscles.

ELECTRONIC TONOMETER

To the Editor:—The interesting editorial "Electronics in the Service of Medicine" in the June 25, 1955, issue of The Journal, page 656, did not mention the electronic tonometer, which has contributed so much to the better understanding of intraocular fluid circulation and glaucoma.

LAW DEPARTMENT

MEDICOLEGAL ABSTRACTS

Chiropractors: Injury to Spinal Meninges During Adjustments.—The plaintiff filed suit for damages against the defendant chiropractor for having negligently caused the death of his wife. From a judgment in favor of the plaintiff, the defendant appealed to the Springfield court of appeals, Missouri. The plaintiff's wife was suffering from a stiff neck, eye trouble, and occasional headaches. She consulted her family physician who gave her a thorough examination and told her that she was suffering from muscular strain and that she needed spectacles. Thereafter, on the advice of a neighbor she went to see the defendant chiropractor. He told her that she had some misplaced vertebrae. The plaintiff, who was present when the defendant examined and treated his wife, testified that the defendant had his wife lie face down on a self-tripping (high-lo) table and that he commenced manipulating her spine, proceeding upward toward her neck. The defendant then adjusted the table top to a perpendicular position, with the patient standing facing the table top, and asked her to see how far she could move her head to the right and to the left. After she demonstrated this point, the defendant grabbed her head and jerked it violently in one direction and then in the other. Each time something popped, and the patient screamed. She then said several times, "I'm falling," but the defendant proceeded to gouge and punch her neck and to roll her head around. The patient was then helped to a chair by the defendant and her husband. She could not hold her head up, her face and hands were numb, and she began to vomit. She said that she did not hurt anywhere, but apparently she was in convulsions. She was helped to a cot, where she continued to vomit and was without control of her movements. Subsequently, the defendant summoned a physician from a nearby office who recommended taking the patient to a hospital. This was immediately done, but the patient remained in much the same condition until she died about 18 hours later.

The physician whom the defendant had called filled out a death certificate indicating the cause of death to be a ruptured congenital aneurysm. A few weeks later the plaintiff had his wife's body exhumed for the purpose of an autopsy. A complete autopsy was made, including an examination of the peritoneum, liver, pleural cavities, lungs, heart, pericardium, heart muscles and valves, aorta, abdominal aorta, kidneys, uterus, brain, membranes, and blood vessels. A portion of the spinal column, consisting of the atlas, axis, and third cervical vertebra, was removed for a separate examination. The autopsy revealed that there was only one condition in the body that could have caused death and that that was an injury to the spinal meninges resulting in intraspinal bleeding and compression of the spinal cord. The examination failed to show a displacement of any of the vertebrae. This opinion was corroborated by another pathologist who examined the removed specimen. The expert witnesses at the trial gave their opinion that the injury could have been caused by the defendant's actions in manipulating the deceased wife's head and neck. Neither the autopsy nor any other evidence corroborated the original diagnosis of a ruptured congenital aneurysm. Two chiropractors, qualified at the trial as expert witnesses on behalf of the defendant, testified that the defendant had done nothing in treating the deceased woman that was not in accordance with the accepted practice of chiropractors generally in that community. One of them admitted, however, that if the adjustment were properly made there would be no chance of injuring a patient.

The defendant first urged that the plaintiff had failed to show that he had acted negligently. The court held that, although the defendant's witnesses had denied that the defendant had done anything other than what was considered as acceptable practice, the jury was not bound by such testimony. From the facts of the case, as presented by the plaintiff's witnesses, the jury could conclude that the defendant must have acted negligently, even though no expert witnesses stated an opinion to that effect. From the further fact that there actually was no displacement of the deceased woman's vertebrae and that the defendant continued his manipulations after the patient evidenced pain, a lay jury could conclude that the defendant did not act in accordance with the accepted standard of practice among chiropractors generally in that community. When a drastic injury occurs to an otherwise healthy portion of the body as a result of chiropractic manipulations, said the court, a jury may conclude that the manipulator acted negligently. The defendant also argued that the plaintiff had failed to show that the injury to his wife resulted from his manipulations. The court rejected this argument since the facts showing the continuity of events indicated that the defendant's acts constituted the causative factor, that there was testimony by competent witnesses to the effect that the injury could have been caused by the defendant's acts, and that the evidence failed to show any other events that might have caused the condition leading to the death of the plaintiff's wife. Other contentions of the defendant were overruled, and the judgment against the defendant chiropractor was accordingly affirmed. *York v. Daniels, 259 S. W. (2d) 109 (Mo., 1953).*

Governmental Hospitals: Liability of Hospital District for Burns Negligently Inflicted on Paying Patient.—The plaintiff filed an action for personal injuries, alleging that while she was a patient in the defendant's hospital she suffered severe burns due to the negligence of the hospital's agents in carelessly applying hot water bottles to her legs when she was under anesthesia. The trial court dismissed the complaint for failure to state a cause of action, so the plaintiff appealed to the Supreme Court of California.

The defendant hospital district was organized under the California Health and Safety Code, which provides for the creation of such hospital districts with the approval of a majority of the voters of each district. The statute provides that the hospitals owned or leased by the districts are to be operated in the best interests of the public health. They may not render professional services but may contract for such services with physicians and surgeons, provided that no profit or gain accrues to the district as a result of such contracts. Rates are to be established that will, so far as possible, make the hospitals self-supporting. The districts also have the power to levy taxes.

The Supreme Court held that the defendant hospital district was a public agency performing a governmental function and was therefore immune from suit without consent of the state. It was further held that such consent had not been given in California, notwithstanding the existence of a statute that set up a procedure for suing the state in a tort. That statute was construed as not extending the tort liability of the state but as providing a procedure for suit where the state was liable under existing rules of law. The Supreme Court said that the district was created primarily for the purpose of protecting the public health, especially in rural areas where the cost of private hospitals would be prohibitive, and that the fact that fees were charged for the services of the hospital did not affect the governmental nature of the function performed. The judgment dismissing the plaintiff's complaint was accordingly affirmed. *Talley v. Northern San Diego County Hospital District, 257 P. (2d) 22 (Calif., 1953).*

Malpractice: Application of Res Ipsa Loquitur.—The plaintiff filed suit for malpractice against the defendant physician. From an adverse judgment he appealed to the Supreme Court of Washington. The plaintiff visited the office of the defendant physician to determine the cause of an excessive amount of phlegm in his throat. At the time of the visit, the plaintiff's voice was clear and normal. The defendant's examination disclosed two small growths on the plaintiff's vocal cords near their apex. These growths were subsequently removed, and immediately thereafter, and up to the time of trial, the plaintiff's voice became hoarse, low-pitched, and difficult to understand, so that he was unable to continue his employment.

On appeal, the plaintiff argued that the defendant's negligence was so grossly apparent that no further evidence was necessary. The Supreme Court rejected this argument. The Court held that as a general rule the negligence of a doctor can be established only by expert medical testimony. A doctor is deemed negligent only if he departs from the normal standards of practice of his community. The standards of the community in question and the question of whether or not the defendant departed from them can be established only by expert medical testimony. Furthermore, said the Court, the cause of the plaintiff's voice condition was a medical cause, and proof of a medical cause must be made by medical experts. The only exception to the rule requiring expert medical testimony is that class of cases in which the doctrine of *res ipsa loquitur* is applied—that is, cases in which the doctor's negligence is so apparent that the negligence can be easily recognized by the laymen on the jury. The Court held that this case did not involve negligence so apparent that expert testimony was unnecessary. Accordingly, the Court affirmed the judgment in favor of the defendant physician. *Nelson v. Murphy, 258 P. 2d 472 (Wash., 1953).*

MISCELLANY

MEETING OF PAN AMERICAN HEALTH OFFICIALS

Directing Council.—The eighth meeting of the Pan American Sanitary Organization's directing council was held in Washington, D. C., in September under chairmanship of Dr. Hector A. Coll, Director General of Public Health in Argentina. The council, composed of delegates from the 21 American republics and France, the Netherlands, and the United Kingdom on behalf of their territories in the Western Hemisphere, meets annually to review the work of the Pan American Sanitary Bureau. Dr. Juan Allwood Paredes, Director General of Public Health in El Salvador, and Dr. Bernardo Henao Mejía, Minister of Public Health in Colombia, were elected vice-chairmen. A budget of $2,200,000 was voted for the year 1956 for continuation of the health programs to be carried out with the guidance of the bureau: also available will be $1,181,365 already allocated to this region by World Health Organization for 1956 and other funds, notably from this region's share of technical assistance money apportioned to WHO by the United Nations, and funds allocated for public health work by the United Nations International Children's Emergency Fund. These funds will be used in about 130 integrated public health programs to be carried out by member governments with the technical assistance and orientation of the bureau.

Long-Range Health Programs.—The council, noting that several member governments have already drawn up plans for their public health programs and budgets for the years 1957 to 1960, urged others to take similar action. The 130 projects to be implemented by the bureau in 1956 cover practically all phases of public health in the Americas. Many are a continuation of existing projects, some of which will be carried forward for several years. Training and education will continue to be an important aspect of the sanitary organization's activities. In the coming year more than 300 fellowships will be granted by the bureau in connection with specific projects, and a number of seminars will be arranged to facilitate the interchange of ideas among health officials of the various countries. Several representatives emphasized that eradication of communicable diseases amenable to such treatment is far cheaper in the long run than the continuous control measures that have been the general rule.

Malaria Eradication.—This year the bureau established a coordination office for the malaria eradication program, with headquarters in Mexico City, Mexico, to coordinate the total continent-wide malaria eradication program. The concept of hemisphere-wide eradication was supported by the council. In reports presented by nearly all representatives on the status of their national antimalaria campaigns, emphasis was placed on the necessity to attack the Anopheles mosquito on a broad front before it develops resistance to the residual insecticides. Malaria is a growing problem where industries are established in malarious regions or where industry draws workers from infested areas. About 300 million cases of malaria still occur annually throughout the world, taking a yearly toll of 3 million lives. Although malaria eradication has been universally accepted, much work and large sums of money will be needed before it becomes a reality. The main burden and responsibility for the program will continue to rest with national governments, with a need for substantial help from international sources.

Yaws and Other Diseases.—The eradication of yaws in Haiti is now practically accomplished. The bureau will assist other governments in yaws eradication during the coming year. This crippling disease still causes untold suffering and economic loss in a number of countries in the Americas and in several islands of the Caribbean. Campaigns aimed at the eradication of smallpox, venereal diseases, and the Aedes aegypti mosquito were also among programs approved for the coming year. Tuberculosis control, environmental sanitation, public health nursing, maternal and child health, and nutrition are included in other projects. Tuberculosis, which used to be the worst killer in many countries, is now being brought under control, and its eradication may be envisioned for the future.

Director's Report for 1954.—The annual report of the bureau director, Dr. Fred L. Soper, was approved by the council. It made a comprehensive survey of the projects in which the Pan American Sanitary Bureau had collaborated with the various health administrations throughout the Americas. These included 77 national health programs in 27 countries and territories, 30 intercountry and continent-wide health programs, and 6 interregional projects. The bureau's work may be divided roughly into three categories: (1) work in connection with the communicable diseases, with emphasis on eradication; (2) strengthening of national public health administrations and coordinating of all services contributing to the health of the population (integration); and (3) training of personnel (education).

Executive Committee.—The seven-member executive committee, which acts as the sanitary organization's governing body when the council is not in session, held brief sessions before and after the council meeting. This year Brazil, Haiti, and Panama completed their three year terms and the directing council elected Bolivia, Cuba, and Nicaragua to fill the vacant seats. Dr. Jiménez Gandica of Colombia was elected chairman of the committee, until its next meeting in April. The four other members are Argentina, Colombia, Paraguay, and the United States.

MEDICAL FILM REVIEWS

NEW FILM ADDED TO A. M. A. MOTION PICTURE LIBRARY

The Heart—How It Works: Health and Safety for You Series: 16 mm., black and white, sound, showing time 12 minutes. Educational consultants: Harold S. Diehl, M.D., and Anita Laton, Ph.D. Produced in 1955 by Audio Productions, New York, for the McGraw-Hill Book Company. Procurable on loan (service charge $2) from Committee on Motion Pictures and Medical Television, American Medical Association, 535 N. Dearborn St., Chicago 10.

This film, by magnified sound, shows how a normal heartbeat sounds through a stethoscope. It then illustrates the structure of the heart, shows the function of its parts, and traces the flow of blood through the heart. Ways of examining the heart and facts about its work load are also given. Some suggestions are made on how to maintain a healthy heart. This film gives an idea of how the heart works and presents astonishing figures about its performance. It is commendable that too much material is not covered. The diagrams showing the action of the heart and the x-rays of the heart are excellent. This is a short, attractive film and is recommended for high school students and adult audiences.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Evaluation of the Calibrated Displacement, Velocity, and Acceleration Ballistocardiograph in Angina Pectoris. J. E. Smith, L. G. Lederer and J. C. Mandes. Am. Heart J. 49:344-359 (March) 1955 [St. Louis].

Twenty patients with angina pectoris were studied with resting electrocardiograms, exercise electrocardiograms, and the calibrated bar magnet ballistocardiograph that measures the displacement, velocity, and acceleration components of body motion simultaneously. The ballistocardiograms of 8 of the 20 patients are described in detail. The ballistocardiograms of all 20 patients showed consistent evidence of abnormality. The resting electrocardiograms were frequently normal or nonspecific. The exercise electrocardiograms were positive in only 50% of the patients. The ballistocardiogram thus was a more sensitive index of abnormality than the electrocardiogram. However, the techniques of measuring motion must be reemphasized. The concept of motion measurement should involve the following principles. Instrumentation should have a linear frequency response from ⅓ of a cycle to at least 16 cycles. Calibration of signal output should be attempted, since amplitudes will not be amenable to comparison among clinicians unless this is done. The motion to be measured should approach a single degree of freedom concept and the distortion produced by the instruments kept at a minimum. There should be no ambient vibration interference from the buildings or ballistocardiograph tables to which the instruments are coupled. The results of the authors' study indicate that definite patterns of abnormality can be obtained in most patients with angina pectoris caused by coronary heart disease if instrumentation and techniques are utilized that fill the demands of proper motion measurement. The diagnostic value of signal differentiation (acceleration) was shown in emphasizing abnormality of form.

A Technique for Recording Carotid Artery Pulsations with Special Reference to Aortic Stenosis. J. E. Smith. Am. Heart J. 49:428-436 (March) 1955 [St. Louis].

In 16 patients with aortic stenosis, pulsations of the carotid arteries, which are easily accessible and close to the centrally generated anacrotic vibrations resulting from aortic stenosis, were recorded through the skin and subcutaneous tissue over the carotid arteries in the neck. A cup was placed over the carotid arteries that could be firmly applied by means of a wooden halter-type neckpiece with an adjustable clamp. A piece of flexible rubber tubing from the cup on the neckpiece was led into a crystal-type pickup that produced an electrical signal proportional to pressure changes in the tubing. Clinical studies indicated that a tubing length of 4 ft. would be ideal. A simple type of differentiation of the signal could be accomplished by utilizing the natural frequency of the air column in the system of closed elastic tubing. This technique is, in essence, the application of a simple Helmholtz resonator. Results showed that it can be used effectively to emphasize the anacrotic vibrations of aortic stenosis when adjusted to the proper frequencies. Of the 16 patients, 12 had "pure" stenosis of the aortic valve, two aortic stenosis and concomitant aortic insufficiency, and two aortic stenosis and probable mitral stenosis. There seemed to be no direct relationship of the amplitudes of anacrotic vibrations to severity of the stenosis. While this is extremely difficult to quantitate, the analysis of functional ability and the ballistocardiograph would indicate that the compensatory myocardial factors are as important as the severity of the stenosis in the production of these vibrations. It is suggested that the amplitudes of recorded vibrations are related to the ability of the left ventricle to accelerate blood forcefully, and thus the forces generated during ventricular systole against a stenotic orifice play an extremely important part in the amplitudes of anacrotic vibrations. These factors seem to be as important as the severity of the stenosis in the cases studied. In patients with aortic stenosis, techniques of pulse tracing and recording instrumentation should be carefully evaluated before any attempt is made to determine physiological significance.

Tuberculous Pleurisy with Effusion. J. A. Myers. A. M. A. Arch. Int. Med. 96:191-201 (Aug.) 1955 [Chicago].

The observations reviewed by Myers were begun in 1920 and were made mainly on groups of school children, university and nursing school students, and persons of various ages in chest clinics and private practice. Tuberculous pleurisy with effusion occurs in persons who have no demonstrable clinical pulmonary tuberculosis and is usually caused by subpleural lesions resulting from focalization of tubercle bacilli after their first invasion. Pleurisy with effusion is usually an allergic phenomenon, the tissues having become sensitized to tuberculoprotein during the first weeks after the initial invasion. Many effusions develop within a few months after the allergy is established. However, they may appear decades later. They occur among tuberculin reactors of all ages from infancy through senility. This report includes 260 persons who had clinically diagnosed tuberculous pleurisy with effusion. None had demonstrable evidence of pulmonary reinfection type of tuberculosis when pleurisy appeared. All reacted to tuberculin, and all had 300 or more cubic centimeters of fluid that was demonstrable by x-ray film inspection. Although recovery of tubercle bacilli is the only incontrovertible diagnostic criterion, they were found in only 76 of this group. In another 116 in whom aspiration was done, organisms were not found, and aspiration was not carried out on the remaining 68 patients. It is now recommended that as much fluid as possible be removed and studied bacteriologically. If this fails, pleural biopsy or surgical exploration may be necessary to determine whether long treatment for tuberculosis is justified. The patients received the treatments that were in vogue at the time they were under observation. It is now recommended that the pleural space be kept as dry as possible; that strict bed rest be employed for at least six months, with graduated exercises for the succeeding six months; and that antimicrobial drugs be administered for at least one year after diagnosis. Treatment is directed not only to pleurisy but also to the underlying cause. Immediate recovery resulted in all patients in this series regardless of treatment. Remote prognosis depends upon conditions existing before pleurisy occurs rather than upon the effusion. Immediately after the initial invasion, tubercle bacilli are focalized not only in the lungs but in various other parts of the body. Any one or more such foci that continue to harbor tubercle bacilli may subsequently release organisms that result in clinical lesions. Pleurisy with effusion is only one of the numerous immediate and remote possibilities. It is doubtful that pleural effusion per se has any effect on subsequent developments. Of the 260 persons constituting this group, 247 (95%) were traced. Eleven had died from nontuberculous conditions. The reinfection type of tuberculosis developed in 23 of the remaining 236 patients. The ultimate prognosis cannot be estimated, because tuberculosis is a lifetime disease, and new lesions may yet appear and old ones may become reactivated. It is suggested that

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1946 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

pleurisy with effusion, like other clinical forms of tuberculosis, may perhaps be prevented by administering antituberculosis drugs promptly after tuberculin conversion while lesions are small and vascular.

The Middle Lobes in Tuberculosis. E. Minetto and S. Pettinati. Minerva med. 46:1749-1756 (June 16) 1955 (In Italian) [Turin, Italy].

Lesions of the middle lobes were found in 82 (13.4%) of the 618 tuberculous patients of a Turin sanatorium. They were located in the right middle lobe in 34, in the lingula in 45, and in both areas in 3. There was evidence that the lesions were primary in only three (0.49%) patients. They were located in the right middle lobe in one case, in the lingula in the second, and in both areas in the third. These findings confirm the rare occurrence of primary tuberculosis in the middle lobes. In the other 79 patients, the disease in the middle lobes was secondary to lesions that were located in the thoracic and apical segments of the upper lobe in 74 cases and in the apical segment of the lower lobe, the so-called Fowler's lobe, in 5. A study of the time of onset and of the clinical and radiological characteristics of these secondary lesions indicated that they had spread by the bronchogenic route. While this route of dissemination has been accepted for secondary lesions to the lingula, which is considered by many the location of choice for bronchogenic dissemination, the same is not true for secondary lesions to the right middle lobe. Yet in this series there were 44 cases of bronchogenic secondary lesions to the lingula and 33 to the right middle lobe. There were only 5 cases of dissemination from the left side to the right middle lobe as compared with 28 cases of homolateral spreading. The respective figures for the lesions to the lingula were 17 as compared with 27. The evolution of the tuberculous lesions in the middle lobes was also studied. Ulceration was found in 11 (13.5%) patients in whom the lesions were secondary: five times in the right middle lobe and six times in the lingula. It was present in the involved lobe of all the three patients in whom the lesions were primary. In many patients in whom the disease to the middle lobe is secondary, these lesions do not undergo cavitation. They are benign, can be treated with antibiotics, and either the parenchyma can be restored to health or fibrotic retraction of the lobe may result. When the bronchogenic lesions of the middle lobes do undergo cavitation, antibiotic therapy may be given. If this fails, surgery, namely exeresis, should be performed. This should also be the treatment of choice for those rare cases of primary tuberculous lesions to the middle lobes that undergo ulceration.

Mesenteric Lymphadenitis. E. R. Bonfigli. Minerva med. 46:1688-1695 (June 9) 1955 (In Italian) [Turin, Italy].

A differentiation is made of mesenteric lymphadenitis into: (1) Ball's tabes mesenterica or caseous tuberculosis of the mesenteric lymph nodes, (2) acute nonspecific mesenteric lymphadenitis, and (3) chronic nonspecific mesenteric lymphadenitis. These three syndromes should be considered as distinct conditions that have in common only the organ they affect. The causative factor is tuberculosis in the first syndrome and nonspecific and perhaps multiple in the other two. The pathogenesis is uncertain and the route of infection may be enterogenous, hematogenous, or lymphogenous. The pathological findings are characterized by caseous necrosis in the first syndrome, acute inflammation (purulent or hyperplastic) in the second, and chronic hyperplastic, rarely calcific, nonspecific inflammation in the third. The clinical course is acute, sometimes dramatic, in acute mesenteric lymphadenitis and extremely chronic in the chronic form. Differential diagnosis is not easy, especially with regard to acute appendicitis. The prognosis is grave for the first two syndromes, but rather benign for the third. Treatment varies; it is antituberculous in Ball's tabes mesenterica, surgical in most cases of acute mesenteric lymphadenitis, and antilymphatic (vitamins and arsenic) in chronic mesenteric lymphadenitis. In the latter, seashore heliotherapy, ultraviolet rays, and, sometimes, operation are indicated.

The Diagnosis of Bronchogenic Carcinoma in Patients with Pulmonary Tuberculosis. M. E. Shafran and J. Kavee. A. M. A. Arch. Int. Med. 96:157-167 (Aug.) 1955 [Chicago].

During a 12 month period at Montefiore Hospital, the antemortem diagnosis of coexisting bronchogenic carcinoma and pulmonary tuberculosis was made and confirmed in six patients, all of whom were men between the ages of 45 and 69. The histories of the six patients are presented and discussed. Five of the six were originally admitted to a tuberculosis ward with a diagnosis of pulmonary tuberculosis. One was admitted to the nontuberculous pulmonary service, since activity of the tuberculous process had been ruled out by studies in the outpatient department. Three of the patients had active pulmonary tuberculosis, in that tubercle bacilli were found in the sputum, and in two of these three cavitation was demonstrable by roentgenologic examination. The other three patients were considered to have inactive pulmonary tuberculosis. The diagnosis of pulmonary neoplasm was suspected at the time of admission in four of the patients. In two of these a round homogeneous density with fuzzy circumference aroused suspicion. In a third patient the characteristic wedge-shaped lesion extending upward from the right hilum with linear projections at the periphery of the lesion strongly suggested a bronchogenic carcinoma. A fourth patient had right upper lobe atelectasis with elevation of the horizontal fissure, which suggested a neoplasm of the appropriate bronchus. In the two other patients the suspicion of malignant disease was aroused when it was noted that there was extension and growth of the lesion on serial x-rays, with concomitant regression of the tuberculosis elsewhere in the lungs on a regimen of adequate antituberculous chemotherapy and bed rest. When the confirmatory diagnostic studies, such as bronchoscopy, cytological examination of sputum and bronchial washings, biopsy of bronchial mucosa, and excision of the scalene fat pads, failed to provide a definitive diagnosis, exploratory thoracotomy was resorted to. The authors feel that, in any patient who shows roentgenologic regression of tuberculous densities on rest and adequate chemotherapy and simultaneous growth or failure of another noncalcific lesion to improve, one may strongly suspect the coexistence of carcinoma of the lung and pulmonary tuberculosis. Patients with pulmonary tuberculosis present a unique opportunity for early discovery of bronchogenic carcinoma, since they undergo frequent roentgenologic examination of the chest. With the increasing frequency of lung cancers and with the shifting incidence of pulmonary tuberculosis into the older age groups, it is important that physicians treating pulmonary tuberculosis be aware of the increasing incidence of bronchogenic carcinoma in these patients.

Natural Duration of Bronchial Carcinoma. J. R. Rignall. Lancet 2:210-214 (July 30) 1955 [London, England].

During 1951 and 1952, 637 patients with bronchial carcinoma were seen at two London hospitals. Of these, 135 were treated surgically, 210 by radiotherapy, and 292 received no treatment likely to prolong life materially. In 255 of this untreated group, sufficient information was available to study the natural duration of the disease. Half of the 255 patients died within nine months from the appearance of the first symptoms, but 14% survived two years or longer. The duration of life from the start of symptoms was found to be significantly influenced by the histological type, the duration of illness before diagnosis, and the presence of metastasis at diagnosis. It appeared to depend, though to a lesser extent, on the nature of the first symptom and the age of the patient; but it was not materially influenced by sex or by the lobe in which the tumor occured. The relation of the duration of life after diagnosis to the length of history before diagnosis is not a simple one. The poorest prognosis was found in those who had had symptoms for four or five months before diagnosis, half of whom died in the next three months. Half of those with symptoms for a year or more lived for a further seven months, and almost a third lived for another year. Published reports and clinical experience suggest that the survival of patients treated by radiotherapy is certainly not strikingly different from those untreated, and the alleged prolonga-

tion of life is not self-evident. Moreover, unless patients have been alloted at random to treated and untreated groups, those given long courses of radiotherapy will almost certainly be better risks than those not treated, who usually are severely ill or cachectic or have widespread metastases.

Use of Corticotropin Gel and Cortisone in Treatment of Severe and Intractable Asthma. B. M. Davies and D. A. Williams. Brit. M. J. *2:293-296* (July 30) 1955 [London, England].

The authors are concerned chiefly with the results of short-term therapy, presenting the effects of treating 44 patients with chronic asthma and 6 with chronic bronchitis with 57 and 7 courses, respectively, of cortisone, corticotropin gel, and/or hydrocortisone. Eleven of the asthmatics were in status asthmaticus; the remaining 33 had intractable asthma. In the asthmatics, 87.5% of the courses gave good results. The temporary relief afforded lasted an average of 30 days but ranged from 1 day to 240 days. In about half of these patients with severe asthma, continuation of hormonal therapy proved unnecessary, but continuation seemed desirable in from 40 to 50% of the patients. This corresponds with the observations of other investigators. Continuous hormonal therapy is beset with risks and requires careful supervision, but short courses seem to be quite safe, if care is taken in the selection of patients. Contraindications to treatment with these hormones were ascertained by a careful history, special inquiry being made about peptic ulcer. Dosage schemes should not be laid down by rule of thumb but should depend on the severity of the asthma and on the patient's response. It is important to distinguish between asthma and bronchitis. The authors observed failure of response in a patient who had purulent sputum but also a marked drop in eosinophils. This patient's condition later improved in response to antibiotics and general measures. Possibly the hormones relieve asthma due to nonpurulent obstruction of the bronchi but fail to relieve the obstruction due to a frankly purulent bronchitis.

Complications of Oxytetracycline and Tetracycline Therapy Related to a Defined Type of Resistant Staphylococcus. J. Brodie, W. Jamieson and T. Sommerville. Lancet *2:223-225* (July 30) 1955 [London, England].

Complications arising in the course of antibiotic therapy have been attributed to antibiotic-resistant strains of micrococci (staphylococci). These complications, which include gastroenterocolitis, sore throat with scarlatiniform rash, sore throat without such rash, balanitis with scarlatina, and urinary infection, have been observed chiefly following the broad spectrum antibiotics, namely, chloramphenicol, chlortetracycline (Aureomycin), oxytetracycline (Terramycin), and tetracycline. The following questions arise with regard to these complications. Are they caused by micrococcic (staphylococcic) infections? Is a special type of Micrococcus (Staphylococcus) responsible? If so, does hospital cross-infection play a part? What connection is there between the complications and the antibiotics? The authors inquired into these questions at the time of a therapeutic trial of antibiotics in bacillary dysentery. They found that, during treatment of bacillary dysentery with oxytetracycline and tetracycline, some of the patients showed complications, especially scarlet fever, sore throat without rash, and gastroenteritis. These complications seemingly were caused by cross infection with a hospital Micrococcus (Staphylococcus) of defined type. The term ac/-POCST, applied to this type, implies that it is agglutinated by absorbed serums "a" and "c" (only) in the live state, is not agglutinated by absorbed serums in the autoclaved state, and is resistant to penicillin, oxytetracycline, chlortetracycline, streptomycin, and tetracycline. The close association of the type of Micrococcus (Staphylococcus) (ac/-POCST) with the patients showing complications during treatment is strong presumptive evidence that it was the organism responsible for them. Two difficulties call for explanation: (1) the failure to isolate it from some of the patients showing complications, and (2) its presence in many patients in the dysentery wards who did not show complications. The first difficulty may be an expression of the selection that inevitably operates when single colonies are picked from the culture plate at primary isolation. The second difficulty is more theoretical than actual, for in communicable disease the carrier rate is often higher than the incidence of illness. The presence of the organism in three nurses, all of whom had worked in the dysentery wards but had not received antibiotics, is evidence that at some stage cross infection had taken place. The control of staphylococcic cross infection may depend not on the search for staphylococcic carriers in general but on the recognition of carriers of defined types of proved pathogenicity, of which ac/-POCST seems to be one.

Leukemia in Survivors of Atomic Bombing. W. C. Moloney. New England J. Med. 253:88-90 (July 21) 1955 [Boston].

Of 92 verified cases of leukemia occurring up to Jan. 1, 1954, in survivors of the atomic bombing in Hiroshima and Nagasaki, 75 were reported on previously, while observations on 17 subsequently observed new cases of irradiation-induced leukemia prompted the author's present report on the various aspects of this disease. Of the 17 patients whose cases were studied in 1953, the disease started in 1 in 1951, in 8 in 1952, and in 8 in 1953. It seems safe to conclude that, although the peak occurrence of leukemia was probably reached in 1951, it will continue to appear but its rate of occurrence in survivors of the atomic bombing is definitely declining. Of the 92 survivors with confirmed irradiation-induced leukemia, 52 had acute or subacute leukemia, and, of the 40 with chronic disease, 39 had the myelogenous type, and only one the chronic lymphatic variety. Data indicated that in man the leukemogenic dose of a single exposure to atomic radiation is high. Biological evidence in survivors indicated that in contrast to previous statements, according to which the dose of gamma irradiation was 25 r at 2,000 m. from the hypocenter and the neutron flux only extended to 800 m., symptoms and signs of severe irradiation sickness were present in survivors out to 2,500 m. from the hypocenter, and lens opacities caused by irradiation were noted at 1,700 m. Since irradiation cataracts were undoubtedly caused by neutrons, the neutron flux probably extended much farther and was more intensive than estimated physically. The implications are that neutrons as well as gamma irradiation were probably involved in the leukemogenesis. Cytological features in the preclinical stage of chronic granulocytic leukemia included the early appearance of a small percentage of myelocytes and metamyelocytes and a very significant basophilocytosis. Separated leukocytes showed extremely low alkaline phosphatase activity, even in the earliest stages of the disease.

SURGERY

The Physiologic and Pathologic Evaluation of the Implantation of the Internal Mammary Artery Into the Left Ventricular Myocardium for the Treatment of Coronary Artery Disease. A. A. Bakst, R. Maniglia, A. Adam and C. P. Bailey. Surgery 38:349-362 (Aug.) 1955 [St. Louis].

The Vineberg operation, in which the internal mammary artery is implanted within the thickness of the left ventricular myocardium, has been said to result in the development of a collateral circulation between the implanted artery and the left anterior descending coronary artery. Quantitation of the retrograde blood flow from the peripheral segment of a ligated and transected coronary artery, which has proved to be an effective method of evaluating changes or augmentation produced in the intercoronary anastomoses, has been used in studying the effect of this operation in dogs. The animals used in these experiments were permitted to lead a normal kennel existence for six months after the operation and before the physiological studies were made; in general, the mortality from the initial procedure was negligible, the operative technique was simple, and the incidence of thrombosis of the internal mammary implant was low (8.9%). The physiological studies showed that the retrograde blood flow from the distal cut end of the ligated left anterior descending coronary artery averaged 2.3 cc. per minute, representing a normal amount of the intercoronary arterial anastomotic flow. Separate clamping, first of the internal mammary implant and later of the left circumflex artery at its origin, proved that this intercoronary anastomotic flow arose almost entirely from the nonoccluded circumflex artery; no increase or change in the flow could be attributed to the implanted internal mammary artery. These physiological results can be explained by the fact that on pathological examination the lumina of the implanted vessels were 95% obliterated by severe intimal proliferation. The vessels were surrounded by fibrous tissue and presented a picture that suggested that they had been walled off by the ventricular myocardium as though they were foreign bodies. The possibility that these findings may be altered by rendering the myocardium ischemic and so creating a need for revascularization is to be investigated in a new series of experiments.

Arterial Hypertension: Comparative Study of Patients Treated by Two Surgical Procedures. G.-E. Cartier. Union méd. Canada 84:887-910 (Aug.) 1955 (In French) [Montreal, Canada].

Fifty patients with arterial hypertension were treated surgically: 18 by dorsolumbar sympathectomy and splanchnicectomy (Smithwick's operation) and 32 by this method plus subtotal adrenalectomy. The amount of adrenal tissue resected varied from 50 to 90%, increasing as the series progressed. The effect of both operations on the following subjective signs: headache, fatigue, and work capacity were equal; they were very good in 91% of the first two symptoms and in 77% of the last. Lesions of the fundus of the eye were equally benefited in both groups of patients, despite the fact that they were more numerous and twice as severe in the patients in whom adrenalectomy was practiced. Electrocardiographic signs were ameliorated in both groups. There was not always a correlation between improvement or the lack of it in one or several of these signs and the effects of surgical intervention on the arterial pressure. Women responded better to the operations than men, but the sex difference was less pronounced among the patients who had the combined procedure. Excellent results were obtained in between 50 and 58% of all the patients and good or excellent results in from 62 to 70%. Greater drops in pressure were obtained in the patients with adrenalectomy. The levels of systolic and diastolic pressure before intervention did not determine the results. The amount of time that has elapsed since operation did not affect the results in patients given combined treatment, whereas it was an influencing factor in patients with sympathectomy alone. The author is convinced that the addition of adrenalectomy accounted for the better results achieved in that group of patients and not some other factor. There also seems to be a parallel between the pressure drop and the amount of functioning adrenal tissue left in the patient. The results of the Thorn test suggested that there was no compensatory adrenal hyperfunction after removal of part of the adrenal glands. The proper use of surgical interventions of the type described is in the treatment of patients with arterial hypertension whose disease has not been arrested by adequate medical therapy pursued for a reasonable period of time.

Recovery with Cardiac Massage After Cardiac Arrest Lasting Thirty-Seven Minutes. L. Eckmann and M. Allgöwer. Arch. klin. Chir. **280**:451-454 (No. 5) 1955 (In German) [Berlin, Germany].

The patient, a woman aged 38, was to be subjected to a brain operation. Anesthesia was induced by means of pentobarbital and a muscle relaxant. During endotracheal intubation, which followed spraying of the pharynx with a surface anesthetic, the patient became pulseless, the pupillary reflexes were not elicitable, blood pressure could not be measured, and the carotid pulse could not be felt. Thoracotomy was done at once through the fourth intercostal space, and, within three minutes after the cardiac arrest, cardiac massage was begun. Pure oxygen was given through the endotracheal tube. Intracardiac injection of first 0.25, then 0.50, and finally 1 mg. of epinephrine had no effect. Cardiac massage was continued for 37 minutes, and then spontaneous contractions set in. At first there were a few systoles, in which apparently only the ventricles participated, but then the heart action was transformed into a normal, sinus-regulated type, which was rhythmical. During cardiac massage spontaneous breathing returned before spontaneous heart action had been restored. No hypoxemic symptoms recurred during the further course, and an electrocardiogram made 20 hours later showed a sinus rhythm frequency of about 100 per minute but otherwise essentially normal conditions. Four weeks later electrocardiography revealed a moderate sinus rhythm and signs of the action of digitalis. The former status was restored after cardiac massage, and there were no disturbances in respiration, digestion, renal function, or speech.

Chlorpromazine as an Aid to Cooling in a Thyroid Crisis. A. R. Hunter. Lancet **2**:173-174 (July 23) 1955 [London, England].

Subtotal thyroidectomy in a hyperthyroid patient was followed by acute hyperthyroidism. The temperature rose steadily to 105 F (40.6 C), and the pulse rate to 200. Thereafter the pulse became uncountable, and auricular fibrillation developed. Despite treatment with digoxin and intravenous iodine and with sedation with phenobarbital, the patient's condition deteriorated steadily. When, 24 hours after operation, it had become apparent that a thyroid crisis was developing, the patient was given a test dose of chlorpromazine, 25 mg. orally, followed by 50 mg. four hours later. A further 50 mg. was given every 8 hours during the subsequent 72 hours. The blankets were at once removed from the bed. When, 30 hours after operation, her condition had deteriorated despite gentle cooling, 100 mg. of meperidine (pethidine) was injected intravenously over 10 minutes. Ice bags were placed in axillae and groins, and on the abdomen, and the patient was placed in an oxygen tent. The nursing staff was instructed to take the oral temperature half-hourly and to remove the ice if this fell below 98 F (36.7 C). Two hours after the initial application of ice the patient became restless, presumably because of discomfort; an additional 50 mg. of meperidine was given intramuscularly, and this dose was repeated every 4 hours for the next 48 hours. Her temperature fell steadily after the application of ice, and next morning her pulse rate was 136, respiratory rate 20, and the temperature 98 F (36.7 C). The ice bags were removed. Five hours later, when the temperature had again reached 101 F (38.3 C) and the pulse rate 160, they were reapplied for a further two hours, after which her temperature again fell to 98.6 F (37 C). Subsequently her condition improved steadily; but administration of meperidine and chlorpromazine was continued so that cooling could be begun without difficulty should the need arise. The patient recovered. The essential problem in thyroid crisis is to reduce the excessive metabolic rate. In the past there has been no completely effective method of doing this, and the condition has carried a very considerable mortality. In the present case the combination of cooling with prevention of shivering by administration of chlorpromazine and meperidine seemed to be responsible for the patient's recovery.

Traumatic Rupture of the Esophagus (With a Report of 13 Cases). J. W. Overstreet and A. Ochsner. J. Thoracic Surg. **30**:164-180 (Aug.) 1955 [St. Louis].

Traumatic rupture of the esophagus is a catastrophic accident that is increasing in frequency and one that is associated with prohibitive mortality and morbidity unless early diagnosis, vigorous resuscitation, and definitive surgical therapy are carried out. Of 13 patients with traumatic perforation of the esophagus treated by the authors from July, 1950, to June, 1953, eight cases were due to diagnostic or therapeutic endoscopy or bougienage, one occurred in the pyriform fossa during attempted passage of a Levin tube with the patient under endotracheal anesthesia, and four were due to penetrating injuries of the neck. The patients were subjected to operation as soon as possible after the diagnosis was made and resuscitative and supportive therapy had been started. Ten of the patients received primary repair with excellent results except for small temporary fistulas that developed in three. The duration of perforation prior to repair in those developing fistulas was 44 hours, 24 hours, and 28 hours, respectively. Mediastinotomy and drainage were done in two patients, the first of whom underwent posterior mediastinotomy and intrathoracic underwater-seal drainage for massive infected pleural effusion and tension pneumothorax 28 hours after perforation; she died on the eighth postoperative day. The second patient underwent cervical drainage of a high mediastinal abscess 32 hours after perforation during biopsy of a high thoracic esophageal carcinoma. The ages of the patients ranged from 16 to 88 years. The time interval from perforation to surgery varied as extensively as did the ages, the intervals ranging from 1½ hours to 44 hours. Of the eight endoscopic perforations, five occurred immediately below the cricopharyngeus sphincter on the posterior esophageal wall, one occurred through a stricture immediately above the esophageal hiatus, and in the two patients in whom drainage only was done the site was in the cervical or upper thoracic esophagus, but the opening was not visualized. All four of the penetrating esophageal injuries occurred in the cervical segment. The authors conclude that their experience is about the same as that of others, in that prompt diagnosis, rapid resuscitation, surgical exploration with débridement of contaminated fascial planes, definitive repair of the esophageal defect, and vigorous postoperative supportive therapy are followed in a large percentage of cases by a rapid and relatively uncomplicated recovery from this previously highly fatal accident.

The Relation Between Sideropenia and Anemia and the Occurrence of Postcibal Symptoms Following Partial Gastrectomy for Peptic Ulcer. S. Wallensten. Surgery 38:289-297 (Aug.) 1955 [St. Louis].

The symptoms of fatigue, pallor, nausea, palpitation of the heart, epigastric pain, and occasionally diarrhea as well, occurring a short time after meals in patients subjected to partial gastrectomy, sometimes referred to as the dumping syndrome, have also been variously designated as postprandial and postcoenal. The term postcibal (i. e., post cibum, after meals, after eating), applied to these symptoms by Meurling, among others, seems on the whole to be comprehensive enough to cover the rest. The incidence of these symptoms, which are sometimes so severe that they endanger the good results of gastrectomy for peptic ulcer, is comparatively high. Some authorities believe that they originate in the small intestine, as a result of such disturbances as jejunal distention, irritation of the small intestine and increased motility therein, hyperemia in the vicinity of the splanchnic nerves, allergy, and the like; others attribute them to conditions such as distention, gastritis, achylia, and the like in the gastric remnant; and still others think they originate elsewhere. Hypoglycemia, reduced serum potassium, and even anemia or sideropenia are among the causes suggested by those in the last group. Critical evaluation of these possibilities leads to the conclusion that, while a number of factors may contribute to the occurrence of postcibal symptoms, they are in all probability usually caused by the response of the small intestine to a sufficiently intense, nonspecific irritation. Epithelial changes in the nails and buccal mucosa have been shown to accompany sideropenia and, if similar changes exist in the intestinal mucosa, the resulting mucosal sensitivity might conceivably play a significant part in the response of the intestine to irritation. Postcibal symptoms have, in fact, been found to occur more frequently in patients with sideropenia than in those with normal hemoglobin and serum iron values. Investigation of 587 patients who underwent partial gastrectomy for peptic ulcer during the period between 1932 and the end of 1949 confirmed the author's previous findings and showed an appreciably higher incidence of postcibal symptoms in patients with definite anemia and sideropenia than in those with normal or slightly reduced hemoglobin content. An increase in the degree of iron deficiency was paralleled by a rising incidence of postcibal symptoms. Iron therapy, administered intravenously because of the poor capacity for absorption often found in patients who have undergone gastrectomy, was given to 21 patients with sideropenia and postcibal symptoms. All but one were considerably improved, and in 14 the symptoms disappeared completely. Improvement was also obtained in two of six patients with postcibal symptoms who had normal serum iron values, but the other four were unimproved. No serious side-effects were noted. Some patients reported a general sense of bodily warmth as well as heat and flushing of the face, but these effects could be avoided by giving the injection more slowly. These findings show that there is every reason to use well planned and executed iron therapy in an attempt to improve the condition of patients with postcibal symptoms accompanied by anemia or sideropenia.

Indications and Results of Surgical Treatment of Recurrences of Malignant Tumors. M. Schwaiger and K. H. Müller. Arch. klin. Chir. 280:536-551 (No. 5) 1955 (In German) [Berlin, Germany].

The authors found follow-up possible in 125 of 153 patients who were operated on for recurrence of malignant tumors at the Heidelberg University Hospital during the decade from 1943 to 1953. One operation for relapse was performed in about half of these patients, and the others underwent from two to five operations for relapse, a total of 216 operations. The fact that a total of 37,000 operations were performed at the same hospital during the period in question indicates that operations for relapses of malignant tumors were comparatively rare. The patients included 35 with mammary carcinoma, in whom 53 operations were carried out for recurrences. The number of operations performed for recurrent lesions in other sites were as follows: 17 in 17 patients with gastric carcinoma recurrences; 23 in 17 patients with colon-rectal carcinoma; 33 in 13 patients with facial carcinoma; 13 in 7 patients with other squamous cell carcinomas; and 12 in 6 patients with miscellaneous tumors. The most favorable results were obtained in relapses of mammary carcinoma and in carcinoma of the lips and cheeks. Although 50% of these patients died within two years after the operation for relapse, 25% experienced remissions of several years' duration and another 25% obtained permanent cures. The fact that among the definitely cured there were some with extensive recurrences that required resections of the thoracic wall indicates that operation may prove effective even in rather advanced processes. In carcinoma in the region of the lip and cheek operation for relapse was followed in one-third of the patients each by cure, remission, or death. In relapses of sarcoma the results were favorable only in the rather mature forms (three fatalities compared with seven cures). In the undifferentiated forms of sarcoma the surgical treatment could not arrest the unfavorable course. In carcinoma of the gastrointestinal tract attempts at radical removal in relapses were ineffective. Search for the factors common to the relapses that responded favorably to operation revealed that they were relapses involving the skin, the superficial soft parts or the scar tissue. Judging by form, localization, and growth, these recurrences were caused by incomplete removal or by surgical implantation of tumor tissue. The authors feel that, in the favorable forms, surgical removal should always be tried. The fact that of those who were cured about 50% had not one but several relapses indicates that in case of repeated recurrences surgical removal should be attempted each time. With regard to the surgical technique, the authors regard it as important that, in order to avoid a new tumor implantation, it should be carried out under general anesthesia; that, if possible, excision should be done with the electric knife; and that removal should extend far into the healthy tissue. Factors likely to cause mechanical, chemical, or physical damage should be kept away from the region of the operation, in order to avoid further relapses.

Spondylolisthesis: A Critical Review of a Consecutive Series of Cases Treated by Arthrodesis. D. M. Bosworth, J. W. Fielding, L. Demarest and M. Bonaquist. J. Bone & Joint Surg. 37A:767-786 (July) 1955 [Boston].

The statistical material presented in this paper is concerned with 115 patients who were treated by spine fusion for spondylolisthesis in the lumbar spine. The report of the surgical results is concerned with 75 patients operated on by a single technique. The forward slip of the vertebral body and the defect in the pars interarticularis in spondylolisthesis represent only a part of the anatomic alteration present in such cases. The arch of the displaced segment tends to provide support for the spine and to prevent further slippage. Removal of the arch is advisable but only if it is replaced by a bone graft to give adequate support. Pain in spondylolisthesis is the result of more than one causal factor. The authors believe it to be due to impingement of malaligned bony elements and to abnormal stress on fibrous or ligamentous structures. Extradural pressure from prolapse of an intervertebral disk occurs occasionally. Pressure from hypertrophied fibrocartilaginous tissue in the pars interarticularis defect was not noted by the authors. Disk degeneration itself cannot cause pain. Earlier the authors had used various surgical techniques, including the Hibbs-type fusion with and without reinforcing iliac strips and tibial H-grafts with and without additional iliac strips. Since 1944 the routine procedure has been to implant an autogenous, cortical iliac graft of the distraction type, supplemented by strips of cancellous iliac bone placed beneath it. Since 1941 the authors, as a rule, removed the fifth lumbar laminar arch. Since 1942 the bone grafts have been placed in contact with the previously denuded stumps of the pedicles of the displaced segment. The arch was removed in 64 instances and left in situ in 11. Of the 75 fusions 66 were from the fourth lumbar vertebra to the sacrum, 6 were from the third lumbar vertebra to the sacrum, 2 from the third to the fifth lumbar vertebra, and one was from the second to the fourth lumbar vertebra. There were no operative deaths. Sixty-five of 73 patients who could be evaluated were asymptomatic. Of the 66 with solid fusion, 62 were free from symptoms; of the 7 with failure of fusion only 3 were asymptomatic.

Clinical Evaluation of 750 Patients with Colon Cancer: Diagnostic Survey and Follow-Up Covering a Fifteen-Year Period. T. A. Shallow, F. B. Wagner Jr. and R. E. Colcher. Ann. Surg. **142**:164-175 (Aug.) 1955 [Philadelphia].

The peak incidence (60.7%) of cancer of the colon in a series of 750 patients occurred in the sixth and seventh decades, with slight predominance in the male (56%). The age extremes were 16 to 92 years. Change in bowel habit is probably one of the earliest symptoms of colonic cancer, 69.3% in this series. Weight loss and anemia were commoner in right colon lesions and obstructive phenomena commoner in the left colon. About 50% of all the cancers of the colon, rectum, and anus were palpable on digital rectal examination. Seventy-seven per cent of the lesions occurred in the lower sigmoid, rectosigmoid, and rectum; three-fourths of these were palpable rectally. Polyps of the colon were demonstrated by barium enema or sigmoidoscopic examination in 16.2% of the patients and another primary colonic cancer in 4%. This emphasizes the probable role of polyps as precursors of colonic cancer. The most significant cause for delay in diagnosis was the assumption by the patient or physician that rectal bleeding was due to hemorrhoids. Change in bowel habit frequently caused no immediate concern. Cardiovascular disease was the commonest surgical handicap encountered; urinary tract invasion or compression justified routine preoperative intravenous urography and sometimes bilateral ureteral catheterization. Many of the patients (28.3%) had late lesions. Thus, 14.8% required decompressive surgery for complete colonic obstruction, an additional 11.6% had palliative surgery, and 1.9% were prohibitive surgical risks. With adequate bowel preparation and the use of the Miller Abbott tube, it is usually safe to perform wide resection with open primary anastomosis of left colon lesions. When optimal conditions are lacking, such as in marked edema, disparity in size of the lumens, or questionable blood supply to either loop, it is safer to perform stage resection with later restoration of continuity. For cancer of the lower sigmoid, rectosigmoid, rectum, and anus, the authors perform abdominoperineal resection with perineal excision including the levator ani muscles. Resection with primary anastomosis is done only when an adequate segment of colon distal to the lesion can be removed and anastomosis carried out above the peritoneal reflection. In anal cancer, abdominoperineal resection was supplemented by bilateral radical femoroiliac lymph node dissection. The resectability rate in this series rose from 82.5% in the first of the three five year periods covered by the study to 89.3% during the last five years. This is among the highest rates reported in the literature. Urinary tract infection accounted for the highest morbidity and renal failure for the highest mortality. Complete five year follow-up study was obtained in 93.6% of the eligible patients. The over-all five year survival was 33.1%, and 94% of these patients were still clinically free of cancer. There was a significant drop in recurrence rate and metastases after the third year. The rectosigmoidal and rectal group of cancer patients showed a higher survival rate than those with right or left colon lesions. Among those patients who had localized lesions without evidence of spread, the five year survival rate in the rectosigmoidal and rectal group was 70.3%. The survival rate was higher in the patients with lesions histologically graded as low or intermediate.

NEUROLOGY & PSYCHIATRY

Presenile Cerebellar Ataxia in Chronic Alcoholics. S. A. Skillicorn. Neurology **5**:527-534 (Aug.) 1955 [Minneapolis].

Six patients with a clinical picture of cerebellar atrophy, characterized by slowly progressive ataxia beginning in middle age, were admitted within a period of six months to the U. S. Naval Hospital, San Diego, Calif. They are presented with a twofold purpose: (1) to emphasize that this particular syndrome should be considered in any case of progressive cerebellar dysfunction with onset in the presenium, especially if there is a history of alcoholism, and (2) to offer the concept that the cerebellar syndrome may be but part of a diffuse degenerative process of the entire brain. The age at onset varied from 39 to 55 years. Duration of the illness was one year for three men, 2 years for one, 5 years for one, and 15 years for the other. All patients admitted to prolonged overindulgence in alcoholic beverages. Initially, three of the patients showed a mild to moderate peripheral neuropathy that disappeared following vitamin therapy and adequate diet. While a satisfactory explanation has never been given for the predominance of cerebellar dysfunction in the lower extremities in this syndrome, it is suggested that the evolutional transition from four-legged to upright two-legged animal ambulation possibly has resulted in redistribution of cerebellar function, that is, adaptation, with functional activity directed toward maintenance of synergy more in the lower than in the upper extremities, and with consequent prevalence of leg incoordination in cases of diffuse degeneration of the cerebellum. The absence of nystagmus in the reported patients probably indicates that the vestibular nuclei and their connections are not involved by the degenerative process, at least not of sufficient extent to produce clinical manifestations. Pneumoencephalographic and psychological studies suggested the presence of diffuse degenerative disease of the cerebrum, in addition to cerebellar atrophy.

Treatment of Some Neuropsychic Syndromes of Old Age with Chlorpromazine. G. Mars and M. Morpurgo. Gior. gerontol. **3**:226-232 (May) 1955 (In Italian) [Florence, Italy].

Chlorpromazine (Largactil) was used in the treatment of 53 patients in the 72 to 86 age group, 4 of whom had involution melancholia, 30 senile psychoses of demential, delirious, and manic-depressive type, 2 epileptic syndrome, 12 Parkinson's syndrome, and 5 subacute alcoholism. The drug was given at first intramuscularly, then orally, in doses of from 50 to 200 mg. daily according to the severity of the condition. The therapy was continued for from 1 to more than 90 days; it was tolerated well and never caused marked side-effects. The most noteworthy effect was the drug's influence on the humor of the patients who, sad and depressed before the therapy, became euphoric and optimistic. The therapy had also a sedative and hypnotic effect. Results were good in 38 patients, in 16 of whom they were definitive. The best results, as to the sedative, hypnotic, or euphoric effect, were seen in the patients with psychosis of delirious type, involution melancholia, subacute alcoholism, and epileptic syndrome. The results were poor and transitory in those with dementia and manic-depressive psychosis, and the condition of the patients with Parkinson's syndrome was not influenced. The serum protein findings were unchanged during and after the therapy, suggesting that the hepatic function was not altered. Some patients gained appetite and body weight. Careful clinical and laboratory studies of the cardiovascular system, liver, and hemopoietic organs and their functions in these patients indicated that old age is not a contraindication to the use of chlorpromazine.

Relapses in Adults with Tuberculous Meningitis: Incidence and Prognosis in Relation to Form of Therapy. H. Sudhof and A. Steinhoff. Deutsche med. Wchnschr. **80**:1085-1086 (July 22) 1955 (In German) [Stuttgart, Germany].

According to the principles established by the World Health Organization, only those patients with tuberculous meningitis can be regarded as cured in whom at least 12 months have elapsed since the onset of the antituberculous therapy. It was observed soon after the introduction of streptomycin that relapses were frequent before, but not after, this period. The 100 adult patients with tuberculous meningitis discussed in this report had all been observed for more than a year. Relapse was mentioned in 21 of them. Eleven of these, however, could not be regarded as true relapses, because in these patients the relapse occurred during the period of treatment, before all meningitic symptoms had subsided. The authors present an illustrative case history, which demonstrates that the patient in question did not have true relapse but that the course of the tuberculous meningitis was characterized by successive bouts or exacerbations. The patients who had this form of tuberculous meningitis had a poor prognosis, in that 8 of the 11 died. Autopsies made in five of the eight fatal cases revealed a rather uniform pathological picture. In addition to old healed tubercles, the meninges also showed new lesions, and in two of the cases lesions typical of all the stages of tuberculous meningitis were present. This suggests that from the beginning the treatment had been insufficient to control the disease process. Cases of that type are no longer observed since isoniazid therapy has been introduced. Ten of the 21 were true cases of relapse. In 6 of these 10 the tuberculous meningitis had been treated with streptomycin only, in one with streptomycin and aminosalicylic acid, and in 3 with streptomycin, aminosalicylic acid, and isoniazid. In 3 of the 10 patients the relapse occurred because the tuberculous meningitis had not been treated adequately. Treatment was continued for only six weeks—in two, because of rapid improvement, and in one, because a psychosis had developed. Observations on these three patients emphasize the need of continuing treatment with the three drugs over long periods. Since the authors have done this, they have not observed a single true relapse. Serial examinations of the cerebrospinal fluid did not provide an early indication of the occurrence of relapses.

Treatment of Tuberculous Meningitis with Tuberculostatic Drugs in Combination with Cortisone. F. Michel and W. Pulver. Schweiz. med. Wchnschr. **85**:717-721 (July 23) 1955 (In German) [Basel, Switzerland].

It has been observed that, in from 10 to 15% of patients with tuberculous meningitis, an arachnoiditis develops, which interferes with the circulation of the cerebrospinal fluid. Since the administration of cortisone has been known to prevent or counteract this arachnoiditis, the authors used cortisone in addition to tuberculostatic drugs in four children and in four adults with tuberculous meningitis. The antituberculous drugs used were streptomycin, isoniazid, and, in some of the patients, aminosalicylic acid. The streptomycin was given only intramuscularly. The isoniazid was given orally, in doses of 5 to 10 mg. per kilogram of body weight, and by intralumbar injection, 20 to 30 mg. per injection, to the first five patients, whereas the other three patients received this drug by oral administration only. Cortisone was given at first in doses of 100 or 200 mg. per day; later this dose was gradually reduced by 25 to 50 mg. and then was discontinued after from three to five weeks. The drug therapy was continued for from four to seven months, and the intralumbar administration for from two to five months. In five of the patients from 10 to 15 months have elapsed since the start of treatment, in two patients 7 months, and the eighth patient has been under treatment for 3½ months. Since the middle of May, 1955, all patients have been free from symptoms. All neurological symptoms subsided completely. The addition of cortisone to the tuberculostatic drugs did not result in the activation of healed tuberculous foci; on the contrary, active pulmonary and hilus lesions showed improvement or clinical cure. Mild adrenal cortical hyperfunction (Cushing's syndrome) appeared in three of the children but disappeared when treatment with cortisone was discontinued. The main effect of the cortisone seems to be that it prevents neurological damage and spinal block with its sequels.

Experiences in the Psychiatric Treatment of Ulcerative Colitis. R. G. Head. J. Louisiana M. Soc. **107**:321-324 (Aug.) 1955 [New Orleans].

The importance of psychological factors in the genesis and course of ulcerative colitis has been recognized by many observers. The author became interested in the psychiatric management of patients with ulcerative colitis when he was consulted about several who had, in addition to their ulcerative colitis, clear-cut suicidal depressive symptoms. The author treated several of them with a course of electric shock therapy, as one would treat any patient with such a severe depression, and he has now managed six cases jointly with an internist and a surgeon. The first patient was a 45-year-old woman who had had from 10 to 20 bloody stools daily for several months, with resulting weight loss and malnutrition. In addition, she was intensely depressed, was anorectic, and slept little. She received a course of eight electric shock treatments with cessation of the diarrhea after the second treatment, followed by constipation. The depression lifted gradually, and the end-result was a severely hypochondriacal person without depression or ulcerative colitis. The response of four of the others was similar and with a better final result. In each of these the diarrhea and depression stopped quickly. The sixth patient received only one electric shock treatment, additional ones being refused. Later a colectomy was performed in this patient. The five patients reacted with much more than the usual memory loss; most had a total amnesia from the hospitalization. After the first treatment, they reacted with extreme suspicion and distrust and directed various paranoid accusations against the doctor. All of these symptoms subsided over a period of weeks. It seemed as if a temporary paranoid psychosis had taken the place of the symptoms of ulcerative colitis. Five of these six patients have been followed for 18 months to two years, and none have relapsed. Perhaps, in acute cases, electric shock therapy may shorten the course of the illness and may even be of lifesaving value.

GYNECOLOGY & OBSTETRICS

Acquired Fibrinopenia in Pregnancy. A. P. Barry, F. Geoghegan and S. M. Shea. Brit. M. J. **2**:287-290 (July 30) 1955 [London, England].

It is generally agreed that an acquired fibrinopenia is responsible for the coagulation defect found in certain obstetric emergencies. This defect is most commonly seen in accidental hemorrhage, but it occurs also in association with amniotic fluid embolism, where it may lead to fatal postpartum hemorrhage. The authors as well as others encountered it after the delivery of a macerated stillborn fetus retained in utero for a considerable time in a rhesus-immunized mother, and very recently they observed it after a missed abortion (eight weeks). The authors speculate on the possibility that fibrinopenia may be responsible for the apparently disproportionately severe hemorrhage sometimes encountered in evacuating the uterus in cases of missed abortion. In any intractable hemorrhage complicating pregnancy, repeated determination of the coagulation time by the Lee and White method should be performed. The authors have been interested in the rapid fibrinogen assay method devised by Schneider in 1952, and they particularly draw attention to a simple colorimetric method for the estimation of plasma fibrinogen described by Shea in 1954. These two methods will detect degrees of fibrinogen deficiency not recognizable by the Lee and White technique. Both are well within the compass of the small clinical laboratory. The authors describe these two methods and present the histories of six patients who were selected in order to demonstrate the various circumstances in which intractable hemorrhage due to a defect of coagulation may be encountered in obstetrics. Patients who show a Schneider titer of 1 in 100 or less (plasma fibrinogen probably below 120 mg.) should be regarded as potential victims of a hemorrhagic diathesis. If hemorrhage occurs it cannot be checked without restoring the blood fibrinogen. Even if there is no manifest hemorrhage, disastrous bleeding may be provoked by active intervention. Since stored blood for transfusion will have a fibrinogen content of 200 mg. per 100 ml. or less, it may not be possible to raise the blood fibrinogen to a safe level by transfusion of whole blood. If pure fibrinogen is not available, a rapid restoration of clotting power may be achieved by the intravenous injection of triple-strength or quadruple-strength plasma (1 pt. [570 ml.] of quadruple-strength plasma yields about 4.4 gm. of fibrinogen).

The Use of Plastic Prosthesis in Breast Plastic and Other Soft Tissue Surgery. W. J. Pangman II and R. M. Wallace. West. J. Surg. **63:**503-512 (Aug.) 1955 [Portland, Ore.].

This report is concerned with the use of Ivalon, an inert plastic sponge material, a polymer formed by the action of formaldehyde on polyvinyl alcohol. The authors mention Oppenheimer's report on the carcinogenic action of other plastics in rats, but, in reviewing the experimental and clinical use of Ivalon by other investigators, they point out that Ivalon sponge has been in situ in some animals for up to five years, and yet no malignancies have developed. The authors use Ivalon sponge in hernia repair, in building up tissues about the face, such as receding chins and nasal deformities, and in the restoration of the contour of the female breast following mastectomy and in the build-up of small breasts. When Ivalon sponge was first used for breast repair, some patients showed excessive drainage, and over 10% of the implants had to be removed because of this; also there was considerable shrinkage of the sponge. The authors overcame most of the shortcomings of the plain sponge by devising a compound prosthesis, in which the inner portion of the sponge is cut away leaving a shell of Ivalon about 5 to 8 mm. thick. The segment of the sponge removed is sealed airtight in a polyethylene sac and reinserted into the shell, like the inner tube in a tire. This prosthesis has the following advantages: (1) the outer shell affords an inert framework that becomes fixed to the surrounding tissue; (2) the inner polyethylene sac prevents further ingrowth of fibrous tissue and prevents collapse of the prosthesis; and (3) the inner sac reduces the accumulation of fluid throughout the sponge, reducing its weight and the danger of drainage. This new type of prosthesis has been used over the last three years in over 400 breast operations with favorable results. A new method of sterilization for the Ivalon prosthesis uses a vacuum, followed by formaldehyde gas for several hours, then vacuum again. This method has largely done away with infections. The authors warn against the promiscuous use of prosthesis to build up small breasts and advise that it never be used in patients with a family history of breast cancer. They also urge that the work be done only by those well qualified in the surgery, anatomy, and pathology of the breast.

Treatment of Dysmenorrhea with a New Analgesic-Sedative. W. G. Caldwell. Rocky Mountain M. J. **52:**701-703 (Aug.) 1955 [Denver].

This report is concerned with the medical management of dysmenorrhea with Fiorinal, a new analgesic and sedative, which contains Sandoptal (isobutylallylbarbituric acid), caffeine, acetylsalicylic acid, and acetophenetidin. The author used this drug in 47 women, whose ages ranged from 18 to 42 years. Except for nine patients who had retroversion of the uterus, no gross pelvic lesions existed in these women. The menstrual cycles were regular. Most of the patients complained of passing clots the first day of flow but not to a degree that could be considered excessive. Forty of the 47 women complained of gradually increasing discomfort commencing two days before and reaching a climax the first day of menstrual flow. The remaining seven complained of gradually increasing discomfort starting five to six days prior to onset and then reaching a peak on the first day of flow. All complained of lower abdominal distention from the sixth premenstrual day until the onset. Restriction of salt intake helped all 47 patients but did not completely relieve pain and discomfort. Thirty-five of the 47 patients had received previous therapy, none with any success. An initial dose of two tablets of Fiorinal, taken at the first sign of cramps, and followed routinely in three hours by one tablet, proved effective in 22 patients. Twenty-five patients required an increased or additional dosage of Fiorinal. Thirty-five of 47 showed excellent response, 18 improving to the point where they no longer required regular monthly medication. No side-effects were noted in any of the 47 cases.

Metastases of Carcinoma of Body of Uterus to Pelvic Lymph Nodes. H. Lefèvre. Ugesk. læger **117:**712-718 (June 2) 1955 (In Danish) [Copenhagen, Denmark].

Clinical investigations based on dissection of the pelvic lymph nodes during operation for carcinoma of the body of the uterus show that metastases to the pelvic lymph nodes occur to a greater extent and at an earlier stage than was formerly believed. They were found in 5 out of 40 patients operated on for carcinoma of the body of the uterus. These results together with results reported from five other sources reveal that out of 212 patients with carcinoma of the body of the uterus in whom dissection of the pelvic nodes was performed, 40, or 19%, had metastases to the pelvic lymph nodes. The tendency of carcinoma of the body of the uterus to metastasize to the pelvis should lead to radicalization of the operative treatment only in suitable cases, in which an extended or modified Wertheim operation would reasonably be undertaken. For patients who cannot tolerate so extensive an intervention, bilateral removal of the lymph nodes in foramina obturatoria and along the large vessels may be recommended.

Triethylene Melamine in the Management of Far Advanced Ovarian Cancer. M. P. Sykes, R. W. Rundles, V. K. Pierce and D. A. Karnofsky. Surg., Gynec. & Obst. **101:**133-140 (Aug.) 1955 [Chicago].

Twenty-six patients with carcinoma of the ovary, who had previously received surgical treatment and usually also x-ray therapy and who then showed recurrent and progressive disease, were treated with triethylene melamine (TEM). The drug was given by the intravenous and oral routes. The intravenous daily dosage was usually 3 to 4 doses of 0.04 mg. per kilogram of body weight (2 to 3 mg.). The injection was usually given into the tubing of an intravenous infusion set. Nausea and vomiting rarely occurred at the recommended dosage, although the patients occasionally complained of anorexia. The drug was available for oral use in 5 mg. scored tablets. The usual dose was 2.5 to 5 mg. per day for one or two days. The tablet was usually taken an hour before breakfast, with water. About half of the patients complained of anorexia, mild nausea, and dizziness at some time during treatment. The average oral dose was 20 to 40 mg. during the first month. The dosage was estimated at intervals of one or two weeks on the basis of the patient's hematological and clinical response. If satisfactory improvement followed, the patient was put on a maintenance dose, while being kept under hematological control. Fourteen of the 26 patients obtained some symptomatic improvement, and 8 of this group showed objective evidence of tumor regression. Improvement usually persisted for from one to three months. One patient showed benefit for a period of 11 months, and another has shown no evidence of recurrent disease for four years. The latter case may represent a spontaneous remission. On the basis of these responses, an adequate trial of triethylene melamine or of a related compound is indicated in patients with nonresectable or recurrent ovarian cancer. Triethylene melamine may precede, follow, or be administered concurrently with, x-ray therapy.

Carcinoma of Breast During Pregnancy. J. R. Firpo. Rev. Asoc. méd. argent. **69:**84-86 (April 15-30) 1955 (In Spanish) [Buenos Aires, Argentina].

Two cases of cancer of the breast in pregnant women are reported. The first patient had a small nodule that appeared several years before pregnancy, developed slowly, and stopped growing for a year prior to pregnancy. After the fifth month of pregnancy the nodule rapidly grew into a tumor that became ulcerated. Biopsy showed carcinoma. The patient refused treatment. She returned to the hospital at full term of pregnancy, in cachexia. The tumor was very large and ulcerated. Delivery was spontaneous with birth of a normal child. The placenta was normal. The course of cancer became accelerated early in the period of lactation and the patient died late in puerperium. The second patient observed a tumor for the first time, coincidentally with early pregnancy. The tumor grew rapidly and became ulcerated. Biopsy showed carcinoma. The tumor was irradiated with protection of the fetus by covering of the mother's abdomen with a rubber apron. The patient had a premature baby in the eighth month of pregnancy, underweight but otherwise normal. The state of health of the patient rapidly deteriorated. Pleurisy from metastases developed early in the puerperium. The author concludes that the treatment of cancer of the breast is the same for pregnant as for nonpregnant women of the same age. For pregnant women there are the following indications: when the tumor is small and pregnancy is in an early stage, abortion and treatment of the tumor are indicated; in all other cases, hormones should be administered, surgery performed, or irradiation of the tumor given for as long as possible to favor viability of the fetus. Hormones, surgery, and radiotherapy are selected in accordance with the clinical type of the tumor. Irradiation is harmless for the fetus if the latter is well protected against it by covering of the mother's abdomen with the proper apron. At full term of pregnancy, spontaneous delivery or cesarean section is followed by castration, exeresis of the tumor, and postoperative radiotherapy or by radiotherapy alone if the tumor was removed during pregnancy.

Hypopituitarism (Sheehan's Syndrome) with Hyperlipemia and Xanthomas. N. Zöllner. Deutsche med. Wchnschr. 80:999-1002 (July 1) 1955 (In German) [Stuttgart, Germany].

The author presents the history of a 34-year-old woman, who at the age of 21 had experienced severe hemorrhages following delivery of a normal child. After that amenorrhea resulted and the woman became increasingly apathetic. She complained of visual disturbances in the right eye. The body hair became scanty and on examination she showed signs of myxedema, xanthomatosis of the skin, hypotension (90/70 mm. Hg), bradycardia (50 per minute), increased blood sedimentation speed, moderate anemia, reduction of the basal metabolism, moderate hypoglycemia, pseudohemophilia, and a lipemia with increase in the neutral fats, phospholipids, and cholesterol. The excretion of corticoids in the urine was noticeably reduced. Ophthalmologic examination revealed fluctuating opacity of the vitreous of the right eye and chronic iridocyclitis. The turbidity of the vitreous as the result of lipemia was probably due to the concurrence of cyclitis and lipemia. The fact that only one eye was involved speaks against the causal role of hormonal factors. Under the influence of a diet with an extremely low fat content, the neutral fats in the serum decreased to normal values. The xanthomatosis likewise subsided, whereas the phospholipids and the cholesterol in the blood remained high and unchanged. Relapse followed when the patient returned to a normal diet. During cautious treatment with a thyroid preparation, the general condition improved greatly and the plasma fats became normalized. The author feels that this was a case of Sheehan's syndrome, which is characterized by hypogenitalism, hypothyroidism, and hypoadrenocorticism, all of which are elicited by hypofunction of the hypophysis.

THERAPEUTICS

Treatment of Cardiac Insufficiency with an Oleander Combination Preparation: Preliminary Results. C. G. Bär and G. Zeitler. Deutsche med. Wchnschr. 80:1038-1039 (July 8) 1955 (In German) [Stuttgart, Germany].

Sixty patients with cardiac decompensation were admitted to the medical clinic of the university of Erlangen, Germany, and were treated with oleandryl compound, one tablet of which contains 0.05 gm. of the total glucoside of oleander, 12 mg. of pentaerythritol (Peritrate) tetranitrate and 25 mg. of sodium cholate. The authors' preliminary report is concerned with 33 of these patients who were discharged from the hospital after four weeks of treatment that was continued ambulatorily with the patients followed up for periods up to nine months. Of these 33 patients, 27 women and 6 men, whose average age was 54 years, 9 had decompensated mitral and aortic lesions, 9 had decompensated hypertension, and 15 had cardiac muscular insufficiency caused by coronary sclerosis. Five of these 15 patients had bronchopneumonia associated with high fever. Five patients with most severe cardiac decompensation were given initial treatment with strophanthin and digitoxin for a short period. Treatment with oleandryl compound was instituted after partial compensation had been achieved. The dose of the oleandryl compound varied according to the severity of the clinical state. In general, treatment was started with three tablets daily and, when necessary, the dose was doubled. Diuresis was the guiding factor. The tolerance to the drug was good; undesirable side-effects such as nausea, vomiting, and diarrhea were not observed, not even after the administration of nine tablets daily. In general, six tablets daily were sufficient for prompt and continued diuresis even in patients with severe decompensation of the right and left side of the heart in whom satisfactory removal of water could not be obtained by combined treatment with strophanthin and aminophylline. Of 23 patients who complained of angina pectoris, 19 obtained complete relief with the oleandryl compound. The evaluation of the patients' electrocardiographic records was difficult because of physiological variations in the daily rhythm. In 27 of the 33 patients, the electrocardiogram showed an abnormal curve with definite signs of damage to the muscle associated with heart action. Repeated electrocardiographic recordings in the course of the treatment with the oleandryl compound did not show excessive bradycardia, disturbances of transmission, and extrasystoles that may be frequently observed in the course of treatment with high doses of digitalis. Pronounced lowering of the ST interval, which may occur in the course of treatment with strophanthin or with the glucosides of Digitalis purpurea or Digitalis lanata, was not observed. Although the number of patients treated with oleandryl compound is small, the results obtained suggest that the drug is of value in the treatment of patients with mild or moderately severe forms of chronic cardiac decompensation, particularly in the treatment of the so-called old-age-heart. The drug is particularly suitable for ambulatory treatment, since a cumulative effect or undesirable side-effects need not be feared even after prolonged administration.

Comparative Clinical Study of Some Glycosides of Digitalis Lanata. F. Testoni and G. Lomeo. Cuore e circolaz. 39:65-85 (April) 1955 (In Italian) [Rome, Italy].

Comparative studies on three glycosides of Digitalis lanata, lanadigin, Digoxin, and lanatoside C, were carried out on 183 cardiac patients with circulatory failure. The results indicated that the therapeutic properties of the three drugs are essentially the same. The following differential characteristics were found: (1) the total initial digitalization dose that is needed when average daily doses are given orally is noticeably greater for lanatoside C (an average of 10 to 12 mg. in three to five days) than for lanadigin and Digoxin (an average of 6 to 8 mg. in three days); (2) the same is true of the daily maintenance doses, an average of 1 mg. for lanatoside C as compared with an average of 0.5 mg. for the other two drugs; (3) the ratio between the effectiveness of the orally given dose and that of the dose given intravenously is higher for Digoxin than for lanatoside C; (4) the duration of the therapeutic effect of lanatoside C is notably shorter than that of the other two drugs; and (5) the onset of toxic side-effects is commoner following the use of lanatoside C. The authors ascribe these findings to a more rapid elimination of lanatoside C through the kidneys and a more prolonged fixation of lanadigin and Digoxin on the heart muscle. They conclude that these two glycosides of Digitalis lanata are more suitable than lanatoside C for the initial treatment with average doses given orally, because the clinical findings are restored to normal more quickly. Lanatoside C gave good results when it was given intravenously. Therefore, when large initial doses are required, as in the presence of paroxysmal attacks, atrial arrhythmias with high ventricular frequency, sinus tachycardia, and all cases that call for urgent treatment, lanatoside C given intravenously in doses of 1.2 to 1.6 mg. in 24 hours is the therapy of choice. For maintenance therapy, lanadigin and Digoxin given orally are more suitable because smaller doses are sufficient, the therapeutic results are more stable, and the oral route of administration is convenient.

Treatment of Benign Arterial Hypertension with Rauwolfia Serpentina: Forty Cases. R. Armas Cruz, M. Alvo, J. Harnercker and others. Rev. méd. Chile 83:283-288 (May) 1955 (In Spanish) [Santiago, Chile].

Forty patients with arterial hypertension were treated with Rauwolfia serpentina. The majority of the patients were women of the average age of 55. Hypertension was benign, either essential or associated with arteriosclerosis in 37 patients, associated with chronic glomerulonephritis in 2 and malignant in 1. The electrocardiogram showed signs of moderate preponderance of the left ventricle in 12 patients. Roentgen examination of the heart showed moderate enlargement of the shadow of the left ventricle in 19 patients. Examination of the fundus of the eye in 27 patients showed arteriosclerosis of the retinal vessels. The treatment was given to patients during rest and on a diet with salt restriction. The preparation used contained 75% of semitotal alkaloids of the drug. It was given orally at daily progressive doses of from 4 mg. to 12 or 16 mg. for an average period of 72 days. Pure crystalline reserpine was used only in rare cases and if so used, temporarily and in daily doses that varied from 0.6 to 1 mg. All patients reported great improvement of headache, palpitation of heart, and tachycardia. Twenty-one patients exhibited complete tolerance of the drug, 16 complained of transient somnolence, nausea, and vomiting, 5 of moderate nasal congestion, and one of bronchitis that made temporary discontinuation of the treatment necessary. The results are evaluated only in relation to the hypotensive effect of the drug. The drug caused lowering of the systolic pressure of more than 20 mm. Hg in 55% of the cases. The percentage was higher in patients with the essential type of arterial hypertension. Only one patient in the group with arterial hypertension with arteriosclerosis did not react to the hypotensive effect of the drug. Low figures of arterial hypertension did not change in some patients who discontinued the treatment on their own accord. The author concludes that Rauwolfia serpentina is of great value in arterial hypertension, chiefly in essential hypertension. The patient with malignant hypertension in the group of patients observed by the author did not report for further observations.

Anticoagulation Treatment with Tromexan and Marcoumar: Micromethod Determinations of Prothrombin-Proconvertin Activity. T. Iversen. Ugesk. læger 117:873-878 (July 7) 1955 (In Danish) [Copenhagen, Denmark].

Since June, 1954, initial anticoagulation treatment with Tromexan-Marcoumar has been applied in 33 patients (27 with coronary thrombosis, 3 with deep venous thrombosis, 2 with thrombosis in the central retina vein, and in one patient prophylactically). In 23 cases the initial dose was 900 mg. Tromexan plus 9 mg. Marcoumar given simultaneously. Twenty-four hours after the initial dose the prothrombin-proconvertin activity had fallen to an average of 27%. In 10 patients who were especially exhausted and/or had lowered prothrombin-proconvertin activity before treatment, the initial dose was 600 or 900 mg. Tromexan plus 6 mg. Marcoumar. Here the average prothrombin-proconvertin activity was 31% after 24 hours. If an immediate anticoagulant effect is wanted, heparin must be given; three or four intravenous injections in the first 18 hours usually suffice. Maintenance treatment was given with Marcoumar exclusively. In most cases a single daily dose allows the prothrombin-proconvertin concentration to be kept within 10 to 30%. The maintenance dose will as a rule lie between 1.5 and 3 mg. Marcoumar, but individual sensitivity varies greatly. Thirty-one patients were treated for more than a week, 20 for more than five weeks. Of the 27 patients with coronary thrombosis, 7 died during treatment. Before start of the anticoagulation treatment the prothrombin-proconvertin activity must be determined, as the continued dosage depends on the initial reduction of the activity. When the maintenance dose is established, determination of the concentration once weekly is generally sufficient, which makes long-time treatment possible. Apart from light nosebleed in one case, no tendency to bleeding or other side-effects was observed during the anticoagulation treatment.

Nonhemorrhagic Accidents in Heparin Therapy. L. Mathieu, M. Rémy, C. Pernot and others. Presse méd. 63:1023-1025 (July 9) 1955 (In French) [Paris, France].

The nonhemorrhagic accidents of heparin therapy manifest themselves either as shock reactions or as blood hypercoagulability without shock phenomena. Though most are without lasting effect, there have been deaths from heparin administration. The incidence of these accidents is small. An analysis of the shock phenomena reported during various programs of heparin treatment shows that they vary widely in form and are independent of the amount injected or the brand used. Their severity is somewhat related to the severity of the disease and the age and condition of the patient. The commonest symptom of the shock phenomena associated with heparin administration is sharp pain in the legs. These accidents appear to be independent of those caused by excessive hypocoagulability. As to their cause, it can be said that imperfections in the products used and the unwitting introduction of pyrogens are becoming rarities, that spontaneous intolerance to heparin is still open to question, and that, rarely, heparin gives rise to intolerance reactions in allergically predisposed patients. However, the most significant type of accident is that occurring during a repeated course of therapy after interruption; here it seems that the particularly strong aggression of abrupt variation in coagulability can cause serious accidents in badly prepared, poorly fortified patients. Accidents of secondary hypercoagulability are also the result of discontinuous or abruptly interrupted therapy. The disturbances in coagulation of the original disease play a large part in the cause of these accidents. The existence of these nonhemorrhagic accidents is not sufficient reason to modify the indications for heparin treatment but should urge better, more careful conduct of the administration of the substance.

Long-Acting Coronary Vasodilator Drugs: Metamine, Paveril, Nitroglyn and Peritrate. H. I. Russek, B. L. Zohman, A. E. Drumm and others. Circulation 12:169-175 (Aug.) 1955 [New York].

The modifying action of four long-acting coronary vasodilator drugs, namely, triethanolamine trinitrate biphosphate (Metamine), dioxyline phosphate (Paveril), glyceryl trinitrate in a sustained-action tablet (Nitroglyn), and pentaerythritol tetranitrate (Peritrate), on the electrocardiographic response to standard exercise (Master-two-step test) was recorded and compared in 21 carefully selected patients with coronary disease. The drugs were administered from one to six hours before the exercise test. Metamine produced little or no significant effect on exercise response as measured electrocardiographically in all the patients. Paveril in some instances was mildly effective, but its action was not sustained and its influence was never striking even with massive doses. Only 6 of the 21 patients showed significant improvement in exercise response following the use of this drug. Paveril does not appear to be as potent as papaverine in comparable dosage. Nitroglyn, despite the effectiveness of glyceryl trinitrate in the treatment of the acute attack of angina pectoris and in prophylaxis when employed before contemplated exertion, gave disappointing results. In the usual recommended dose of 2.4 mg. (0.04 grain), the preparation appeared totally inert. With larger doses, 4.8 to 9.6 mg. (0.08 to 0.16 grain), Nitroglyn produced slight to moderate improvement in exercise response for a period of six hours after its administration in almost two-thirds of the patients tested. Nevertheless, the drug failed to induce a normal electrocardiographic response to exercise in any of the 21 patients, a result far surpassed by the sublingual administration of glyceryl trinitrate and by Peritrate respectively. Peritrate, in a dose of 10 to 20 mg., showed a marked modifying influence on the response to standard exercise in 14 of the 21 patients tested. The effect of this agent was comparable to that of glyceryl trinitrate, but its action, after a latent period of 60 to 90 minutes, could be demonstrated as long as five to six hours after the administration of a therapeutic dose. Clinical response was markedly attenuated or totally abolished, however, when Peritrate was taken after food. Of the four drugs tested, only this agent appears worthy of the designation "long-acting coronary vasodilator." Peritrate appears to satisfy the need for prolonged coronary vasodilatation in most patients with angina pectoris.

Experiences with a New Local Antibiotic. H. Klima. Wien. klin. Wchnschr. *67:524-526 (July 22) 1955 (In German)* [Vienna, Austria].

Nebacetin, a combination of neomycin and bacitracin, was applied locally in 26 patients with pulmonary tuberculosis who were treated at the sanatorium Baumgartner Höhe near Vienna, Austria. Of 14 of these patients who had been treated previously with sulfonamide, penicillin, oxytetracycline, and streptomycin and had become resistant to these drugs, 5 had chronic fistulas with mixed infection occurring after empyema and reconstructive plastic surgery; 6 had fistulas occurring after plastic repair following lobectomies and pneumonectomies, respectively; 2 had fistulas of soft tissues; and one an internal bronchial and external thoracic wall fistula after pneumothorax empyema. Instillation of the drug, which was diluted with isotonic sodium chloride solution to an amount of from 2 to 10 cc. according to the size and extent of the sinuses of the fistulas, was carried out with a blunt needle through a drain; 5 to 10 mg. of Neomycin and 250 to 500 units of bacitracin per 10 kg. (22 lb.) of body weight were administered three to four times in the course of one week, or daily if required. In 9 of the 14 patients, the fistulas healed completely in the course of two to six months of treatment; the 5 other patients were improved. The satisfactory results obtained in these 14 patients prompted the author to broaden the indications for local treatment with Nebacetin, and to use the drug for the postoperative treatment of five patients who had undergone cavernostomy, for cavity acupuncture and cavity plombage, respectively, in five patients, and as an aerosol in two patients with bronchiectasis. In the five patients with cavernostomies, cleaning of the wall of the cavity occurred rapidly, and fresh granulation tissue particularly rich in vessels developed. Cavity smears and sputums became rapidly free from bacteria. Similar phenomena apparently occurred in the wall of the cavity of the patients with cavity acupuncture. In the patients with bronchiectasis, the amount of sputum diminished and the offensive odor from the mouth subsided. Complications or undesirable side-effects did not occur in any of the 26 patients. The value of the new local antibiotic seems to consist of its efficacy in patients who already have become resistant to penicillin, oxytetracycline, and streptomycin and of the fact that, as a purely local antibiotic, it may hardly cause resistance or hypersensitivity to the drugs that are generally used.

Study on Removal of Water with Diamox in Cirrhosis of the Liver. E. Rissel, H. Schnack and F. Wewalka. Schweiz. med. Wchnschr. *85:698-702 (July 16) 1955 (In German)* [Basel, Switzerland].

Carbonic anhydrase, a zinc-containing protein, is contained in the tubular cells of the kidneys and apparently influences the kinetics of hydration and dehydration of carbon dioxide in these cells. Diamox (2-acetylamino-1,3,4-thiodiazole-5-sulfonamide), a powerful carbonic-anhydrase–blocking agent, was given to 13 patients with decompensated cirrhosis of the liver, 4 patients with cardiac decompensation, and 2 patients with edema of different genesis. Of the 13 patients with cirrhosis of the liver, an abundant diuresis occurred in 8 who thus showed a satisfactory response to Diamox. No difference in this response was observed in patients with ascites and general edema and in those with ascites only. The reduction in body weight varied from 5 kg. (11 lb.) to 15 kg. (33 lb.). Satisfactory diuresis also resulted from the administration of Diamox in four of the six patients with the other disorders. The authors recommend a dose of 250 mg. of Diamox given orally in one tablet in the morning on three successive days in the course of one week and repeated for three to five weeks. Most of the patients who did not respond to the administration of Diamox with a satisfactory diuresis had a markedly increased excretion of sodium and potassium. This dissociation of the water metabolism and the electrolyte metabolism, in contrast to the otherwise strictly coupled water and electrolyte excretion, seems to be noteworthy with regard to the mechanism of sodium retention in patients with cirrhosis and cardiac disease. The drug was ineffective in patients with excessive potassium excretion. Its effect could not be enhanced by the additional administration of potassium. Undesirable side-effects of Diamox were not observed. Mild drowsiness occured, and on several successive occasions one patient had tremor that always subsided after discontinuation of the drug.

Modern Therapy of Gout. F. Koller. Schweiz. med. Wchnschr. 85:693-697 (July 16) 1955 (In German) [Basel, Switzerland].

Twenty-seven patients with 51 attacks of acute gout were treated with Irgapyrin, a proprietary pyrazolidin containing equal parts of phenylbutazone and aminopyrine, and with phenylbutazone (Butazolidin). The average daily dose of Irgapyrin given intramuscularly was 1.5 gm., and the average daily dose of phenylbutazone given orally varied from 0.6 to 1 gm. A complete remission resulted within 48 hours in 42 attacks; Irgapyrin was given in 27 of these attacks and phenylbutazone in 15. Because of their rapid and reliable effect, Irgapyrine and phenylbutazone are superior to colchicine and corticotropin (ACTH) in acute attacks of gout. Phenylbutazone enhances the excretion of uric acid and thus produces a pronounced decrease of the serum level of uric acid. The intramuscular injection of Irgapyrin should be given into the gluteus medius, above and outside the gluteus maximus, to prevent the undesirable side-effect of sciatic pain. Other undesirable side-effects such as a tendency to retention of sodium chloride and water, leukopenia, and agranulocytosis are of minor importance in the course of the short-term treatment of the acute attack of gout. In chronic tophaceous gout, probenecid (Benemid) is the drug of choice; its average daily dose is 1 gm.

Treatment of Granulocytic Leukemia with Myleran and Demecolcin. W. Pribilla and G. Stollberg. Deutsche med. Wchnschr. 80:1027-1029 (July 8) 1955 (In German) [Stuttgart, Germany].

Of 16 patients between the ages of 18 and 71 with chronic granulocytic leukemia, 10 were treated with 1,4-dimethanesulfonoxybutane (Myleran) and 6 with desacetyl-methylcolchicine (Demecolcin), an alkaloid obtained from Colchicum autumnale. The initial daily dose of Myleran varied from 4 to 6 mg. given orally, and the maintenance dose varied from 2 mg. given three times in the course of one week to 2 mg. given daily. The maximum total dose of Myleran was 458 mg. given in the course of 130 days. Results were satisfactory in 9 of the 10 patients treated with this drug. The general condition was improved and the number of leukocytes was reduced. There was an increase in the number of erythrocytes and in the hemoglobin level. The effect of the drug became apparent within three weeks. The peripheral blood cell count showed a decrease in myeloblasts and a reduced shifting to the left. The blood count in several patients was restored temporarily to normal. Leukopenia and thrombopenia were not observed. Diminution in the size of the spleen was impressive and rapid. Only one patient with a relatively immature type of leukemia and a large number of myeloblasts in the blood and in the marrow did not respond to Myleran. Demecolcin was also given orally; the initial daily dose was one tablet containing 1 mg. of the drug. The daily dose was increased up to 10 mg. The total dose varied with the individual patient and frequently reached several hundred milligrams. In general, the tolerance to the drug was good. Occasional side-effects consisted of loss of hair and herpetiform stomatitis. Satisfactory results were obtained in three of the six patients treated with Demecolcin; a complete remission occurred in one of these patients. Both Myleran and Demecolcin inhibit chiefly the myelopoiesis and are, therefore, suitable for the treatment of chronic granulocytic leukemia. When used cautiously, both drugs have few undesirable side-effects and therapy may be continued safely for many months. The therapeutic effect of Myleran seems more reliable than that of Demecolcin.

Data on Deaths Due to Agranulocytosis in the Netherlands. *B. J. Salomonson. Nederl. tijdschr. geneesk.* 99:2044-2047 *(July 9) 1955 (In Dutch) [Haarlem, Netherlands].*

Because of the increased recording of agranulocytosis on death certificates, the author, who is connected with the central statistical office in the Netherlands, investigated this problem, giving particular attention to the cause of agranulocytosis.

Analysis of the causes of fatal agranulocytosis for the year 1952 showed an increase in the group in which drugs were the cause, and in 1954 the group with "unknown cause" showed an increase, but the author feels that the "unknown" cause may also have been a drug in many instances. In a table the author shows data on 184 fatalities of the years 1952 to 1954, in which agranulocytosis was given as a cause of death. Drugs were indicated as the cause in 103 of these cases, and "cause unknown" was listed in 39 cases. Further analysis of the 103 cases in which drugs were the cause revealed that a proprietary brand of aminopyrine had caused the agranulocytosis in 41 cases, another proprietary containing equal parts of phenylbutazone and aminopyrine was responsible for 13, sulfonamide preparations for 13, and gold for 6 fatalities; various other drugs were responsible for fatal agranulocytosis in the other 30 cases. The aminopyrine and other antipyretic drugs had been prescribed chiefly for chronic rheumatic disease.

Heparin and Corticotropin (ACTH): Analogies and Differences. F. De Matteis. Minerva med. **46:**1800-1804 (June 20) 1955 (In Italian) [Turin, Italy].

The results of clinical and experimental studies of the author and of German workers seem to support the hypothesis advanced by De Matteis in March, 1953, that heparin has a corticotropin-like action. The properties common to the two substances are: (1) stimulation of the adrenals and the thyroid and marked involution of the thymus (more evident after a short treatment period); (2) induction of severe endocrine alterations after prolonged administration of the two substances; (3) a hypocholesterinemic effect, especially on esterified cholesterol; (4) an action that modifies paper electrophoresis with a decrease of the albumins and a marked increase of the globulins; (5) an "anti-sludging" action; (6) an antianaphylactic action, which is less evident with regard to corticotropin; (7) a marked effect (antihyaluronidase and antiexudative) on the phenomena of diffusion; (8) a constant effect on peripheral eosinopenia; and (9) an antirheumatic action with respect to acute rheumatic disease in children. The endocrine alterations that are induced by the prolonged administration of the two substances are: (1) a marked loss of weight with partial atrophy of the skin and (in the animal) a more or less diffuse loss of hair; (2) a decrease in the weight of the testicles and the spleen; (3) hyperemia and edema of the hypophysis; (4) an increase in the weight of the liver and the kidneys; and (5) a slight increase in the weight of the thyroid. The action of the two substances differs with regard to the blood coagulation process, heparin prolonging it and corticotropin shortening it. However, if the two substances are used concurrently, the anticoagulant effect of heparin is increased. The reciprocal interferences and the eventual synergisms between the two substances are possible, however, only when large doses of heparin and pure preparations of corticotropin are used.

PATHOLOGY

Mycelial Forms of Coccidioides Immitis in Sputum and Tissues of the Human Host. M. J. Fiese, S. Cheu and R. H. Sorensen. Ann. Int. Med. **43:**255-270 (Aug.) 1955 [Lancaster, Pa.].

Coccidioides immitis ordinarily exists in two distinct phases, the saprophytic and the parasitic; the former, in which the fungus presents itself as a mycelial mass of hyphae, occurs in external nature and culture mediums, while in the parasitic phase the fungus has the appearance of an endosporium or spherule that occurs in animal tissues. Under certain conditions the spherules may be observed in artificial culture mediums, but, as a rule, the hyphae have not been observed in the tissues of the host. The first exceptions to this rule were the recently reported observations of hyphae of Coccidioides immitis in two types of benign residual pulmonary lesions, namely, chronic cavitation and chronic granuloma. Of 98 patients with coccidioidomycosis studied at the Veterans Administration Hospital in Fresno, Calif., 17 had persistent pulmonary lesions without dissemination. Nine of the 17 patients had cavities and 8, granulomas. Mycelial forms of Coccidioides immitis were observed in the sputum of four of the nine patients with coccidioidal cavities of the lungs. This finding has not been previously reported. Pulmonary resection or lobectomy was performed in 12 of the 17 patients, eight times for cavities and four times for granuloma. Mycelial forms of the fungus were observed in the pathological specimens of three patients with cavities and of three others with granulomas. Mycelial forms are most likely to be found on the surface of the wall of a cavity or within the necrotic debris of a granuloma. Mycelial forms will be observed with increasing frequency in tissues and discharges when the search is made in the right place with adequate stains, such as the Hotchkiss-McManus stain or fountain pen ink. Despite the theoretical risk associated with the presence of mycelial forms in the sputum of patients with coccidioidomycosis, contagiousness of coccidioidomycosis has not been demonstrated.

Interpretation of Tuberculous Lesions After Chemotherapy. J. C. Dick. Lancet **2:**216-223 (July 30) 1955 [London, England].

A fairly definite picture is now available of the changes that take place in tuberculous lesions after chemotherapy with different drugs, although there is considerable overlap in the changes found in untreated cases on the one hand and in treated cases on the other. This report is concerned chiefly with the average reactions to various drugs. The differences between the changes in recent tuberculous lesions after chemotherapy with a combination of drugs including isoniazid and those after a streptomycin combination suggest that isoniazid enables a toxic factor to be removed and real healing to occur. The same difference is present early in the treatment of chronic lesions, enabling a larger proportion of isoniazid-treated lesions to attain a satisfactory quiescent stage. Histological evidence is presented for the persistence throughout chemotherapy of dormant bacilli, that is, of bacilli that are in a state of metabolic inactivity, not reproducing, not susceptible to antibiotics, not necessarily capable of growth on ordinary media, perhaps not visible on microscopy, but able to reassume any or all of these properties. Chemotherapy with a single drug leaves a considerable proportion of lesions active, probably by altering the metabolism of the organisms so that they are no longer affected by the drug. In vitro testing for the sensitivity of the organism to the drug, although it is the only method available, is not a fully reliable index of this altered metabolic state. Streptomycin and isoniazid appear to influence the metabolism of the pathogenic organisms in different ways, and given in full doses they are apparently synergistic, since the best healing of lesions is obtained with this combination. Patients with recent lesions should be treated with a combination of chemotherapeutic drugs that includes isoniazid, to obtain resolution. The drugs should be used in their full therapeutic doses, that is, isoniazid, 200 mg. daily; streptomycin, 1 gm. daily; and aminosalicylic acid, 10 to 20 gm. daily. Diminished dosage scales should not be tried unless tests have shown them to be as effective clinically, bacteriologically, and histologically as the full doses. Patients with mixed old and recent lesions should receive similar treatment, to obtain as much resolution as possible. Resection may have to be employed to remove the remaining lesions.

RADIOLOGY

Cervical Air Myelography: Review of 130 Cases. F. Murtagh, W. E. Chamberlain, M. Scott and H. T. Wycis. Am. J. Roentgenol. **74:**1-21 (July) 1955 [Springfield, Ill.].

Air myelography is a harmless and effective method of visualizing the cervical canal and cord. It has a definite diagnostic value and is often sufficient for accurate localization, even demonstrating in some cases types of involvement of the spinal cord that cannot be seen with positive contrast. Care must be taken to secure the best possible contrast and detail in the roentgenograms, because the negative contrast obtained with air is certainly less striking than that provided by the radiopaque agents. Accurate diagnosis with air myelography depends on painstaking study of stereoscopic films of good technical quality and careful correlation of the findings so obtained with the neurological findings and the clinical symptoms exhibited by the patient during the procedure. Small quantities of air (5 cc.) are sufficient to demonstrate the lower edge of a lesion that completely blocks the cervical spinal canal, but larger quantities are needed for the visualization of nonobstructive lesions. The authors therefore devised a method of examination in which, by maneuvering the patient into various positions, 40 or 50 cc. of air injected into the lumbocaudal canal can be moved into any desired section of the spinal canal. Localized sensation, ranging from mild pressure to moderate pain, will be felt by the patient as the air seeks its upper level in the spinal canal and his subjective reaction can be used as a guide in following its upward progress. The air itself is innocuous and completely absorbable. Encephalomyelography, in which air is exchanged for fluid in the cerebrospinal canal in 10 cc. increments, was found to be the most effective method of visualizing the cervical canal and the cord and its relationship to the brain. It is recommended in cases in which the other two methods have failed to produce satisfactory visualization or in which a combined study is desired. Air myelography by one or more of these methods was carried out 142 times in 130 patients with symptoms suggesting cervical spine or cord abnormality seen at Temple University Hospital during the period from 1934 to 1949. Malformations of the cervical spine with cord compression, trauma to the cervical spine, intervertebral disk herniations and osteophytosis, and space-taking lesions of the cervical canal were among the conditions in which useful diagnostic information was obtained. The excellent visualization of the cord provided by air myelography in the cervical region is especially valuable in patients with degenerative lesions of the central nervous system. An appreciable widening of the visible air column beyond one-third the width of the bony canal in patients presenting clinical evidence of central nervous system disease without a demonstrable encroaching lesion suggests cord atrophy regardless of the measurable cord thickness. Individual variations and variability of roentgenographic magnification prevent the establishment of a fixed figure for normal cord thickness, but in all the cases in which a diagnosis of cord atrophy was made myelographically the cord measured considerably less than 8 mm. in thickness. Air myelography possesses the added advantage of being completely roentgenographic; the films obtained can be studied repeatedly by several examiners, eliminating the personal equation found in roentgenoscopy with opaque media.

Uptake and Blood Level of Radioactive Iodine in Hyperthyroidism. R. A. Newburger, S. Silver, S. B. Yohalem and S. Feitelberg. New England J. Med. **253**:127-130 (July 28) 1955 [Boston].

Data obtained from the study of 500 consecutive patients referred to the Thyroid Group of the departments of medicine and physics of the Mount Sinai Hospital were used in comparing the merits of two radioactive diagnostic techniques. The thyroid uptake at 24 hours after the tracer dose and the blood plasma levels of protein-bound I^{131} at 72 hours after the tracer dose were determined in each patient. The patients were classified as normal (euthyroid) (404) or hyperthyroid (96) before the I^{131} studies were carried out. The group as a whole included only patients who had had no previous treatment directed to their thyroid glands. Patients who had received stable iodine medication in any form were either excluded or a period of time sufficient to ensure the disappearance of all effects produced by such medication was allowed to elapse before the tests were made. Comparison of the results obtained showed that uptake studies are less accurate as a diagnostic method than the determination of protein-bound I^{131} levels at 72 hours after the tracer dose. Acceptance of a critical value for the protein-bound I^{131} of 0.27% of the administered dose per liter of plasma was associated with eight diagnostic errors, or 1.6% of errors in classification. These figures were increased to 36 and 7.2%, respectively, when the critical uptake value was taken as 61%. A critical range, rather than a critical value, had to be selected in order to reduce the diagnostic error of the uptake method to that obtained by the determination of the protein-bound I^{131} (1.6%). This range was fixed at an uptake between 42% and 69%; when values below 42% were used to diagnose the euthyroid state and those over 69% were used to diagnose hyperthyroidism, the total diagnostic error was the same as that obtained by the protein-bound I^{131} method, that is, 1.6%. The number of patients left unclassified by the use of this diagnostic range, however, was 127, or 25% of the entire series, as opposed to no cases left unclassified when the protein-bound I^{131} method was used.

Radiation Sickness in Man Following the Administration of Therapeutic Radioiodine: Relationship Between Latent Period, Dose-Rate and Body Size. J. D. Abbatt, W. M. C. Brown and H. E. A. Farran. Brit. J. Radiol. **28**:358-363 (July) 1955 [London, England].

The authors observed the symptoms of radiation sickness in 28 of 38 patients who had received a total of 44 doses of radioiodine in the form of I^{131}. The quantities administered varied from 29 to 200 mc.; these doses were given orally, after fasting, on 39 occasions and intravenously on 5. All patients were kept in bed; the only movements they made were those involved in the measurement of iodine uptake in functioning tissue and those required in routine nursing. The patients suffered from a number of clinical conditions, and there was a considerable variation in the volume, distribution, and activity of the functioning thyroid tissue present in each patient. Prior to irradiation all received treatment wtih an antithyroid drug in order to increase the uptake of iodine in the thyroid tissue when the drug was withdrawn. The symptoms resembled those occurring after a single x-ray dose. The latent period prior to onset of symptoms after radioiodine administration varied between 4 and 13 hours, compared with latent periods of 2 to 5 hours after medium voltage x-rays. It is suggested that the dose rate may be an important factor in the production of the symptoms of radiation sickness.

Further Consideration of Deaths and Unfavorable Sequelae Following the Administration of Contrast Media in Urography in the United States. E. P. Pendergrass, P. J. Hodes, R. L. Tondreau and others. Am. J. Roentgenol. **74**:262-287 (Aug.) 1955 [Springfield, Ill.].

Of 3,300 questionnaires sent to the membership of the American College of Radiology, 1,371 were answered, representing a response rate of 41.5%. Of the 1,371 replies, 1,249 gave complete information and were used in the authors' survey of deaths and unfavorable sequelae following the administration of contrast mediums for the study of the urinary tract. The two most commonly used mediums, iodopyracet (Diodrast) and sodium iodomethamate (Neo-Iopax) accounted for approximately 94% of the urinary tract studies. Sodium acetrizoate (Urokon Sodium) was used in an additional 4.6%. The quantity of contrast mediums injected in the average-sized adult was 20 to 30 cc. With the exception of sodium acetrizoate, which was used relatively frequently in 70% concentration, the higher concentrations of the mediums were rarely used in intravenous urography. Thirty-one deaths, not previously recorded in the literature, occurred after the intravenous administration of the contrast mediums. Twenty-five deaths occurred in the course of the urographic examination, and six were delayed or not clearly caused by the procedure. These deaths occurred over an 11 year period (1942 to 1952) in a series of approximately 3,800,000 urograms. In a previous survey published by Pendergrass and co-workers in 1942, 661,800 urographic examinations were reported and there were 26 deaths. Thus the percentage of deaths in the recent survey is exceedingly low. Brief histories of each of the 31 patients who died are given. The immediate deaths were preceded by dyspnea, cyanosis, hypotension, and convulsions. Sensitivity tests were performed in 15 of the 25 cases of immediate death and were interpreted as being negative. Negative hypersensitivity tests are not reliable. It is generally believed that careful history with particular emphasis on allergy is important. Many workers combine this information with one of the sensitivity tests. In the presence of a positive test and a strong allergic history, the procedure of urography is not recommended. There is a definite trend toward the use of antihistaminics before or during the procedures of urography. Current ideas about the reactions to contrast mediums, the allergy problem, and preventive measures are briefly discussed. Many mechanisms of the mild and severe reactions are not understood and further clinical and fundamental research is not only desirable but essential.

BOOK REVIEWS

International Symposium, The Hypophyseal Growth Hormone: Nature and Actions. Editors: Richmond W. Smith, Jr., M.D., Physician-in-Charge, Division of Endocrinology, Henry Ford Hospital, Detroit, Oliver H. Gaebler, M.D., Head, Biochemistry Department, Edsel B. Ford Institute for Medical Research, Detroit, and C. N. H. Long, M.D., Sterling Professor of Physiology, Yale University School of Medicine, New Haven, Conn. Symposium was sponsored by Henry Ford Hospital and Edsel B. Ford Institute for Medical Research, Detroit, and held at hospital Oct. 27-29, 1954. Cloth. $12. Pp. 576, with illustrations. Blakiston Division, McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 36; 95 Farringdon St., London, E.C.4, England, 1955.

Although no new facts or new viewpoints of major importance are here recorded, this volume gives the significant and established facts regarding the growth hormone and its effects. It is attractive, well arranged, and adequately illustrated, and appeared in the unprecedentedly short time of six months after the conference. It is arranged in five major sections, which are devoted respectively to bio-assay, the preparation and physicochemical properties of growth hormone, effects of the growth hormone on certain structures, the growth hormone and energy sources, the growth hormone and cellular systems, and the influence of the growth hormone on the mammary gland and on human metabolism. Fortunately, before plunging into the minute discussions of various aspects of the effects of the growth hormone in higher animals, the book is introduced by Paul Weiss, who with profundity discusses the biological phenomenon of growth in its broadest sense. Particularly excellent chapters cover our knowledge of the chemical nature of the hormone and the reliable tests of its effects, including a new test by Russell. The interrelations of the growth hormone with the other anterior hypophysial hormones, e. g., corticotropin, or with the hormones produced by other endocrine glands, such as insulin, constitute another field succinctly dealt with in this book.

The carping critic will discover and announce in no helpful way that the actual method of biochemical operation of the growth hormone has not been elucidated by all this effort. The comment is invidious and can be met by the simple statement that we do not as yet know completely the mechanism of action of insulin and its participation in carbohydrate metabolism. It was necessary to discover insulin, to purify it, and to then reap the rich harvest of experimentation with it. It was similarly necessary to demonstrate undeniable growth in animals as a result of anterior pituitary extracts and to detect the substance causing this growth. It has been established that the dramatic cessation of growth in hypophysectomized animals is due solely to the absence of this substance and that its subsequent presence will restore normal growth or lead to excessive growth (gigantism). The isolation of the growth hormone was more difficult, for the pituitary, unlike the pancreas, which has only one or two internal secretions, possesses six or seven of these substances. The book shows that a significant beginning effort in one direction, to elucidate the mode of operation of somatropin, is occurring, i. e., an examination of its possible effects on various enzyme systems by Gaebler and Bartlett. It was quickly seen that the pituitary thrust its ubiquitous influence into many phases of carbohydrate, protein, and fat metabolism. We now know that the growth and adrenotrophic hormones are primarily concerned here, and the clearly established metabolic effects of purified growth hormone are given in the monograph. This field was opened up by the early demonstration of hypophysial diabetes and by Houssay's discovery of the dramatic amelioration of diabetes from pancreatectomy if a concurrent hypophysectomy is done. Over 20 years of research have as yet not completely elucidated these phenomena.

The book's defects, which are few, include the omission of a badly needed author and subject index. It is not too much to state that because adequately trained participants in the symposium have brought this extensive and important material together into one place, the book will be indispensable for workers in the field and, indeed, for investigators in other fields of medical research.

The Postnatal Development of the Human Cerebral Cortex. Volume V: The Cortex of the Fifteen-Month Infant. By J. LeRoy Conel, Research Associate in Pathology, Children's Medical Center, Boston. Cloth. $12.50. Pp. 221, with 235 illustrations. Harvard University Press, Cambridge 38, Mass.; Oxford University Press, Amen House, Warwick Sq., London, E.C.4, England, 1955.

This monograph is the fifth volume in a series devoted to a general survey of the postnatal development of the nerve cells in the human cerebral cortex for the purpose of observing what changes occur in the morphology of the neurons as development proceeds. In the present volume the cytoarchitectonic state of development at the age of 15 months is described, with some comparisons with brains at 12, 13, 14, and 18 months. Nine normal brains were studied. Criteria of selection and techniques of preparation and study of the material are described in volume 1 of the series. The text is devoted to a detailed exposition of the cytoarchitectonics of the cortex using the following criteria of development: (1) width (breadth) of the cortex and each horizontal layer; (2) number of nerve cells; (3) size of nerve cells; (4) condition of chromophil substance; (5) state of development of neurofibrils; (6) size, compactness of structure, and length of processes of nerve cells; (7) number, size, and patterns of distribution of pedunculated bulbs on neurons; (8) size and number of exogenous fibers; and (9) state of myelinization of nerve fibers. The text descriptions are organized according to these criteria for 43 areas, regions, and zones of the cerebral lobes and the rhinencephalon. A summarizing chapter discusses the findings in relation to earlier stages. In this section, there are also interesting speculations on possible correlations of structure with function in the light of these findings. The numerical data obtained from this study are presented in seven tables. Illustrations of microscopic sections from each area make up the greater part of the 109 plates and provide a photographic atlas of corticocellular anatomy as revealed by several neurological staining methods. The author's style of writing is plain and straightforward. Tables are of full page size and are remarkably uncluttered and easy to use. The photographic illustrations, which make up about one-third of the book, are of high quality. There are 32 references, a table of contents, and no index. The appearance of the book is pleasing, and it is well bound. It is difficult if not impossible adequately to summarize the findings reported in this work without extensive reference to the preceding stages of development that are set forth in previous volumes of this series. The present volume is a product of researches dedicated to the painstaking task of detailed study and exposition of the cytoarchitecture of the postnatal cerebral cortex, researches that are indispensable to advances in our understanding of the broader fields of cerebral function and behavior. The subject matter of this volume (and the series), because of its highly specialized nature, would not interest the casual reader, but rather those investigators whose researches require reference to detailed accounts of cerebral cytoarchitecture.

Pathology for the Surgeon. By William Boyd, M.D., F.R.C.S., F.R.C.P., Lecturer on Humanities in Medicine, University of Toronto, Toronto, Canada. Seventh edition. Cloth. $12.50. Pp. 737, with 547 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, England, 1955.

This new edition of a work last published in 1947, under the title, "Surgical Pathology," has been extensively rewritten, and some material added, much of which can be categorized as pathological physiology. The author is well known for his undergraduate textbook of pathology. This textbook is expressly intended as an adjunct to postgraduate surgical instruction. The material is largely confined to diseases of surgical interest but, within this limitation, is widely inclusive. It is arranged by

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

system and organ and contains careful outlines. Bibliographies referring to more detailed discussion are appended to each section, and for the most part these are up-to-date and pertinent. Although an attempt has been made to present the material from the point of view of the clinician, this has not been entirely successful. For example, no account is given of the obscuring of the hilar structures by the inflammatory reaction accompanying acute cholecystitis or of the intimate relation of many duodenal ulcers with the head of the pancreas. This sort of pathology is of little interest to the pathologist, but of great importance to the surgeon. The defect is nowhere more obvious than in the illustrations. Excellent microphotographs are used, but the gross material is almost exclusively black and white, for the most part fixed, and often isolated in such a fashion as to make it difficult to relate to the whole organism. Little indication is given of the relation of the pathological process to the choice of surgical procedure. With the exception of the sections on cardiovascular diseases, which are inadequate, the text presents an excellent, lucid, and concise review of the disease states usually falling within the scope of the surgeon and presents controversial aspects fairly. It should be of great value as a supplement to clinical experience.

Radiographic Atlas of Skeletal Development of the Knee: A Standard of Reference. By S. Idell Pyle, Ph.D., and Normand L. Hoerr, Ph.D., M.D. Cloth. $4.25. Pp. 82, with 29 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1955.

The successors of the late Wingate Todd of the Brush Foundation and the department of anatomy of Western Reserve University have had access to one of the nation's principal collections of roentgenograms of the developing skeletons of normal white children of known age and social background. When they set about producing an atlas of the knee from birth to full maturation at the age of 18, they did a workman-like job. As in any atlas, the plates are the principal offerings, the written material being confined to a description of the plates and a discussion of the methods used in selecting from among many hundreds the particular roentgenograms reproduced in the atlas. In the early months of postnatal life, the changes in the size and shape of epiphyses and in the shape of the ends of the shafts adjacent to them are easy to see once they have been pointed out by the authors, and the development of the tibial tuberosity is a dramatic incident of the years between 12 and 17. For some of the intermediate years, however, the changes are much more subtle. The authors stress the fact that even in normal material, selected as carefully as theirs has been, some boys of 6 will show knee development that usually does not come until a child is 8, while others will not reach the 8 year development until the age of 10. It is unfortunate that after all these years so little of the Todd material has seen the light of day in a form available to the radiologists and clinicians who need it. Painstaking atlases like this book and the earlier ones on the hand are needed perhaps by anthropologists, but clinicians would be better served by a less meticulous but more complete atlas covering the foot, pelvis, spine, pectoral girdle, elbow, and skull. Professor Hoerr and his associates at Western Reserve are uniquely situated to prepare such a complete atlas, and their publisher should see to it that they do so in the near future.

Cardiology Notebook for Preliminary Instruction in Medical Curricula. Editorial Board: *Alfred P. Fishman, M.D., chairman, and others.* Columbia University College of Physicians and Surgeons. Cloth. $2.50. Pp. 97, with illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 99 Great Russell St., London, W.C.1, England; 1955.

This small volume is not intended to be exhaustive or for the specialist. It does not replace larger textbooks or substitute for bedside teaching; it supplements rather than replaces. The arrangement is simple; for instance, on one page are specimens of electrocardiograms, and on the facing page a description of what may be observed and some pertinent case history data. This volume should be found interesting and informative by the student and also by the practitioner.

Philosophische Propädeutik der Medizin: Einführung in die allgemeinen geistigen Grundlagen (Geschichte, Philosophie, Biologie, Psychologie). Von Univ.-Professor Dr. Albert Niedermeyer. Band 1, Allgemeine Pastormedizin in zwei Bänden. Cloth. 128 schillings; 22.50. Swiss francs. Pp. 547. Verlag Herder, Wollzeile 33, Vienna 1, Austria, 1955.

The significance of this book is not immediately clear from the title page. It is the first of two volumes intended (page 2) to enable the medical student to find what could not be offered in his other medical courses, "especially a critical attitude toward the dogmatically transmitted descent theory, the biology of natural selection, and medical psychology." From page 132, one gathers that the book has developed in connection with a course in pastoral medicine required by the theological faculty of the University of Vienna. Accordingly, it covers in scholarly detail the whole field of medical philosophy and ethics, down to such minute questions as whether the papyraceous fetus has a soul at any time (page 483) and when the soul appears in the normal product of conception (page 412). The author's command of theological and philosophical literature is immense, and the results are important. His considerations lead him, for instance, to ridicule as insane (page 254) the suggestions of eugenicists for the improvement of the human race, to accept Kinsey's methods as right but his inferences as wrong (page 142), to denounce Einstein's relativism in science as leading to hopeless agnosticism (page 115), to blame Malthus (pages 171, 172) for ideas that Malthus explicitly deprecated, and to declare that "there can be no medical ethics" as long as science continues to teach Darwin's "false doctrine of evolution" (page 509). His line of reasoning finally leads him, as many others have been led, to defend not only the terrorizing of Galileo but also the burning of Giordano Bruno (page 115). This frightening conclusion should strike the student of logic as a *reductio ad absurdum* and should prompt him to question every premise and deduction in the book. To the author, however, there is but one truth, and it is knowable (page 115).

Any human act is necessarily followed by an endless train of consequences; hence, every physician realizes that his mission is more than just the relief of physical pain and the solution of immediate survival problems. His work is therefore sufficiently complex, but in Niedermeyer's philosophy there is the added difficulty that the fetus is tainted with original sin (pages 103, 491). Accordingly, the author is more concerned about the possibility of an eternity in limbo for the unbaptized than the possibility of a mere lifetime in earthly institutions for the unwanted or the handicapped. In his system of thought, the role of the obstetrician becomes complicated indeed. Most physicians will find this uncompromising philosophy confusing and cruel. In any case, the author has set it forth in black and white for all to judge.

Essentials of Biological and Medical Physics. By Ralph W. Stacy, Ph.D., Associate Professor, Laboratory of Biophysics, Department of Physiology, Ohio State University, Columbus, David T. Williams, Ph.D., Ralph E. Worden, M.D., Associate Professor, Physical Medicine and Rehabilitation, College of Medicine, Ohio State University, and Rex O. McMorris, M.D., Associate Professor and Chairman, Department of Physical Medicine and Rehabilitation, University of Louisville Medical School, Louisville, Ky. With introduction by Otto Glasser, Ph.D., F.A.C.R. Cloth. $8.50. Pp. 586, with illustrations. McGraw-Hill Book Company, Inc., 330 West 42nd St., New York 36; 95 Farringdon St., London, E.C.4, England, 1955.

The subjects discussed in this book include biophysical mechanics (such as motion, acceleration, elasticity, viscosity, and contraction), heat and thermodynamics, acoustics (including ultrasound), radiation (visible light, geometric optics, ionizing radiations), and electricity. Applications to therapy are suggested, but the book is occasionally weak and misleading on these points (e. g., ultraviolet radiation as a treatment for roentgen burns, page 260). The intention is to emphasize physical principles rather than therapeutic details. Applications to other aspects of medicine, however, are presented occasionally in especially interesting fashion. Examples are the use of polarized light to reveal the stresses in models of bones, the microscopy of contracting muscle, the physiology of dark adaptation, the effects of acceleration on aviators, the principle of the electron microscope, the uses of the centrifuge microscope, and the medical aspects of nuclear radiations. Since this book is probably destined to be a pioneer work in an important field, it is to be hoped that future editions will eliminate a number of faults. For example, opening chapters need to be illustrated by more specific instances. The section on instrumentation defines a "precision index" that, being based on mean deviations obtained by disregarding algebraic signs, does not fit well into further statistical procedure. It might be supplemented by consideration of validity and reliability indexes and of the conventional measures of central tendency and dispersion. The illustrations are good, the bibliography is adequate, and there is an index. The book should stimulate medical students, and it is recommended to physicians who wish to inform themselves about the rapidly developing field of medical biophysics.

Neuroglia: Morphology and Function. By Paul Glees, M.A., D.Phil., M.D., University Demonstrator and Lecturer in Physiology, University Laboratory of Physiology, Oxford, England. Publication number 260, American Lecture Series, monograph in American Lectures in Neurology. Edited by Charles D. Aring, M.D. Cloth. $5. Pp. 111, with 44 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1955.

This is a survey concerned with the nature of the glia of the central nervous system. It is primarily a review of the pertinent literature. As such, it should prove useful as a point of departure for one unfamiliar with this literature. Very few personal observations of the author are presented. The treatment of this material is superficial. Commonly, the conclusions only of the various writers are given without any of the evidence on which those conclusions were based. Some sections, such as that on gliosis, are surprisingly brief. The glia of the neurohypophysis and pineal body are mentioned on page 1 and never referred to again. Although the author continually mentions both fibrous and protoplasmic astrocytes, he at no time discusses their morphological differences or provides the reader with any information as to how he may distinguish between them. The author frequently implies that a recent writer is responsible for some concept that is actually far older and attributable to entirely different investigators, e. g., pages 14 and 15, "scheme of glial histogenesis" attributed to Kershman (1938), and page 51, "chemical trans-synaptic transmission of nervous impulses" ascribed to Eccles (1953). The author almost constantly uses the noun, glia, for the adjective, glial ("glia fibres," "glia apparatus," "glia network," "glia preparation"). There are several amazing errors in proofreading, e. g., "Wernicle" for "Wernicke." The almost complete lack of photomicrographs is surprising; the few that are reproduced are poor. On the other hand, the drawings are simple and well reproduced, except for figure 12, which is at too low a magnification. There are over 11 closely printed pages of references. The press work is good, and the index is adequate.

The Story of Medicine. By Kenneth Walker, M.A., M.B., F.R.C.S. Cloth. $6. Pp. 343, with 51 illustrations. Oxford University Press, 114 Fifth Ave., New York 11, 1955.

In the first part of this book, medical discoveries and medical discoverers are dealt with in chronological order. Medical pioneers are depicted as their fellow men saw them, against a background of their own times. In the second part, the rise of specialization and the division of medicine into a number of different fields of research are discussed without placing events in strict chronological order. Whereas medicine originally advanced in a haphazard way, no medical theory or discovery being accepted until it made its entry into the world at the right psychological moment, current medical progress has become more impersonal and is more and more the result of collateral advances both in the medical field and in allied scientific disciplines. Reading this book should provide a rewarding experience for the reader, be he a physician or a member of the laity, as the engrossing story of medicine is traced through the ancient civilizations, the medieval period, and the Renaissance down to the present era. Physicians and their art have always had a fascination for the world at large, and this book should further cement that feeling.

Surgical Physiology of the Adrenal Cortex. By James D. Hardy, M.S., M.D., F.A.C.S., Professor and Chairman, Department of Surgery and Director of Surgical Research, University of Mississippi, University, Miss. Publication number 266, American Lecture Series, monograph in Bannerstone Division of American Lectures in Surgery. Edited by Michael E. De Bakey, M.D., Professor of Surgery, Baylor University College of Medicine, Houston, Tex., and R. Glen Spurling, M.D., Clinical Professor of Surgery, University of Louisville, Louisville, Ky. Cloth. $5.75. Pp. 191, with 34 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto, Canada 2B, 1955.

This book is concerned with function of the adrenal cortex in conditions of interest to surgeons. It is well written and displays evidence of a deep knowledge of the subject by the author. Following an introductory chapter, four sections of the book are concerned with decreased adrenocortical function due to stress evoked by surgical operations, burns, malnutrition, and cancer. Chapters on increased function of the adrenal then follow. These are concerned with cortical hyperplasia and adrenal tumors. The book closes with a section on the present status of corticotropin and cortisone in conditions that the surgeon may encounter. In a special chapter, the author evaluates the present status of bilateral adrenalectomy as a treatment of essential hypertension and metastatic cancer, and most surgeons will agree with his conclusions. In hypertension, adrenalectomy offers at best only a moderate hope of significant improvement in any given patient. In some patients with advanced mammary cancer, adrenalectomy will produce considerable improvement.

Talking with Patients. By Brian Bird, M.D., Associate Professor of Psychiatry, Western Reserve University, Cleveland. This material was published in *American Practitioner and Digest of Treatment* for May, 1955. Cloth. $3. Pp. 154. J. B. Lippincott Company, 227-231 S. 6th St., Philadelphia 5; 2083 Guy St., Montreal, Canada; Sir Isaac Pitman & Sons, Ltd., 39 Parker St., Kingsway, London, W.C.2, England, 1955.

This book fills a needed place in the armamentarium of the practitioner of medicine. It is safe to say that, all too frequently, the practitioner devotes too little time to a discussion of the patient's problems with him and by him. If more attention were given to this phase of medicine, there would be fewer cult practitioners. The book is clearly and well written. It is divided into parts dealing with the problems of adults and those of children. It might well be described as a psychology primer. Unfortunately, most of the work has to do with history taking, and too little is devoted to advice and instruction after the diagnosis has been established. The book will be appreciated particularly by those who have made the mistake of using leading questions. In the comedy "Harvey," the young psychiatrist was attempting to find out how the cordial and genial alcoholic came to name the phantom Harvey. Very knowingly and very intently, he asked him what his father's name was. Obviously the answer he expected was Harvey. To the psychiatrist's great surprise and consternation, the answer was John. Avoidance of such a mistake is clearly outlined in this book. The problems dealt with are mainly psychological and sometimes psychiatric. The author, by his training and work, is particularly well fitted to discuss this pattern of treatment. This book should, and I believe will, be read by many practitioners. The general practitioner, internist, and surgeon should profit by it. It cannot be called a deep reference work but rather a handy desk type of reference book.

Clinical Biochemistry. By Abraham Cantarow, M.D., Professor of Biochemistry, Jefferson Medical College, Philadelphia, and Max Trumper, Ph.D., Basic Science Coordinator, Naval Medical School, National Naval Medical Center, Bethesda, Md. Fifth edition. Cloth. $9. Pp. 728, with 54 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London W.C.2, England, 1955.

The authors have rewritten their popular book because they think the gap between clinical medicine and "fundamental" biochemistry and physiology (which gap this book bridges) has narrowed sufficiently so that the practicing physician can read technical treatises. In short, they believe that the elementary treatment used in the earlier editions is no longer appropriate. These remarks do not mean that the text is difficult to read; the style is as lucid and smooth as ever. Every topic the reviewer can think of that relates to biochemical approaches to diagnosis or management of clinical disorders is treated here. Recent theories on topics treated before are incorporated along with much new material on liver and kidney function; abnormalities in plasma protein; nucleic acids; metabolism of uric acid, prophyrin, iodine, and potassium; lipoproteins; fatty liver; acid-base balance; biochemical aspects of diet; and the diagnosis of disorders in the functioning of endocrine glands, especially of the thyroid and adrenal glands. The chapter on hormones and endocrine function was written with A. E. Rakoff, who also helped in the fourth edition. As in earlier editions, directions are not given for performing tests and assays, because such directions are available in laboratory manuals. To keep the book to a reasonable size, the authors have adopted smaller type and have relied on the clarity of the type face and the heavy leading to make the text clearly legible. Space also is saved by giving brief lists of selected readings instead of longer bibliographies and by omitting references in the text. Biochemical abnormalities in the disease states are no longer listed separately, because this information can be obtained through the index. The table of contents and indexes are extensive and seem to be accurate. Every physician who relies to any extent on the clinical laboratory for help in diagnosis and prognosis should have access to this book.

The Prevention of Disease in Everyday Practice. By Isadore Givner, B.S., M.D., F.A.C.S., Associate Clinical Professor of Ophthalmology, New York University Post-Graduate Medical School, Maurice Bruger, M.Sc., M.D., C.M., Associate Professor of Medicine, New York University Post-Graduate Medical School, New York, and contributors. Cloth. $20. Pp. 964, with 51 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1955.

This interesting approach to prevention of disease rests to a large extent on the imposing list of contributors and to the editorial guidance of the authors. The book is simply written, the chapters logically divided, and the descriptions adequate for this type of presentation. One will not find extensive or theoretical discussions but rather highlights of clinical features that are particularly pertinent to the subject under discussion. It should prove to be a useful and handy reference book for the practitioner, especially when he integrates it with other more exhaustive treatises on the special subjects that are embraced in this volume. Perhaps the potential usefulness of the book can be summed up by referring to it as a working handbook.

Handatlas der Cystoskopie und Urethrocystoskopie. Von Dr. med. O. Kneise, a.o. Professor für Urologie an der Martin-Luther-Universität Halle, und Dr. med. M. Stolze, dozent für Urologie, Martin-Luther-Universität Halle. Fourth edition. Cloth. 44 marks. Pp. 112, with 130 illustrations. VEB Georg Thieme, Hainstrasse 17-19 Aufg. C, Leipzig C 1, Germany, 1955.

This is a new edition of an atlas first published in 1907. The third edition was published only two years ago, and, apparently as a result of wide demand, the fourth edition has now been printed. Changes in the contents of this edition are few. The book consists largely of a series of aquarelles of lesions in the bladder as seen through the cystoscope. As in previous editions, this atlas has an advantage in the fact that the pictures were made by urologists who were also artists. The aquarelles offer life-like reproductions of the different pathological lesions described. The atlas should be of great help to the beginner in the use of the cystoscope.

Pelvo-Spondylitis Ossificans: Rheumatoid or Ankylosing Spondylitis. A Roentgenological and Clinical Guide to Its Early Diagnosis (Especially Anterior Spondylitis). By Ragnar Romanus and Sven Ydén. Translated by Joan Whitehouse. Cloth. $8.50. Pp. 163, with 55 illustrations. The Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11; Ejnar Munksgaards Forlag, Nørregade 6, Copenhagen K, Denmark, 1955.

In this monograph, the disease we commonly know as rheumatoid spondylitis, is described under a new name, pelvo-spondylitis ossificans. The authors' purpose in writing the book appears to be to trace the course of this entity from its inception to the final stages. It is based mainly on clinical and roentgenographic observations in a large series of patients with rheumatoid spondylitis. The authors discuss clinical signs and symptoms of the early sacro-iliac involvement, as well as the spinal lesions and the paravertebral calcification noted in pelvo-spondylitis ossificans. The first part consists of descriptive material, and the second is devoted to roentgenograms of the various phases of rheumatoid spondylitis. The book is printed on good paper in a large type that is easily read. The illustrations might have served the reader better had they been incorporated with the descriptive material rather than confined to a separate section. The bibliography is complete, although the references in the text at times interfere with the effectiveness of the writers' style. The book might have been of greater value, if there had been a chapter on the treatment of this disease. This monograph adds little to what has already been written on the clinical and roentgenographic findings of this subject. It has value, however, as a reference book.

Society and Medicine. Iago Galdston, M.D., editor. New York Academy of Medicine, lectures to laity, no. XVII. Cloth. $3. Pp. 131. International Universities Press, Inc., 227 W. 13th St., New York 11, 1955.

For the past 20 years, the New York Academy has been actively engaged in acquainting the general public with current advances in medical progress. The earliest lectures dealt with specific diseases, but in recent years they have touched on distinctive trends in medical and scientific thinking in order to orient and guide a better medically informed public. This small book comprises six lectures devoted to the theme that society and medicine are intricately interrelated. "They suggest ways in which we may effectively come to grips with the problems, change the methods and improve the processes both of medicine and of societal existence." The first essay deals with diseases and their local setting; the second is concerned with the thesis that ethics are rooted in biology; and the third demonstrates the roles of conflicts, deprivation, and frustration in neurotic behavior. The remaining essays discuss the extent to which environment can affect hereditary potentials, the medico-social factors involved in the process of growing up, and the importance of man's nutritional environment. This book is both thoughtful and provocative and is recommended for mature readers.

Principles of Medical Statistics. By A. Bradford Hill, C.B.E., D.Sc., Ph.D., Professor of Medical Statistics in University of London (London School of Hygiene and Tropical Medicine), London. Sixth edition. Cloth. $4. Pp. 314, with 13 illustrations. Oxford University Press, 114 Fifth Ave., New York 11, 1955.

In pleasing contrast to the obscurity, evasiveness, and affectation of many other books in the field, this one makes an uncompromising frontal attack on the subject, giving the necessary details accurately. The author has kept in mind the questions that most medical readers will want him to answer and is aware of the difficulties most likely to beset the student. He has supplied an excellent set of numerical problems; the answers are worked out fully on pages 271-287. The necessary tables are included, and there is a good index. An entirely new chapter on clinical trials and corresponding changes in the opening and closing chapters are a feature of this edition. It is recommended.

Practical Oral Surgery. By Henry B. Clark, Jr., M.D., D.D.S., Chairman, Division of Oral Surgery, School of Dentistry, University of Minnesota, Minneapolis. Cloth. $8.50. Pp. 392, with 223 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1955.

This small book, begun as a textbook for undergraduate dental students, is believed by its author to have "taken the form of a handbook of what the dentist in general practice should know about oral surgery." Both these purposes have been admirably accomplished by the use of a sequential approach to each problem and a profuse use of excellent illustrations that include line drawings, wash drawings, photographs, and roentgenograms. Captions of illustrations are concise, as is the text material, which is presented in an expanded outline form. The absence of the traditional chapter on local anesthesia may be a disadvantage to some possible purchasers. The chapters on hospital practice, drugs and pharmaceutical preparations, and the art of practice are entirely new to textbooks of oral surgery and appear to be ample justification for the book. The style is concise, the printing excellent, and the index complete. To those for whom it was intended, this should be a welcome first edition.

QUERIES AND MINOR NOTES

TETANUS IMMUNIZATION FOR FOOTBALL PLAYERS

To the Editor:—*Our high school football field is used also as a show ground for a junior fair; cattle, horses, and other livestock are stabled and paraded on it. Should players using this field be required to have tetanus immunization? If so, how frequently should booster shots be given?*

Charles H. Denzler, M.D., Sumner, Wash.

Answer.—If horses, cattle, and other farm animals are stabled, paraded, or grazed on an athletic field, contamination of the soil with tetanus and other clostridial spores is highly probable. The practice of using such an area for a football field is unwise. Players using this field should be required to have a series of three injections of tetanus toxoid for the production of basic immunity against tetanus. Although it is now established that the basic immunity persists for 12 or more years after immunization, it would seem wise to give each football player at the beginning of the season a booster shot. This would afford him an adequate level of tetanus antitoxin circulating in his blood during most or all of the football season. In the event of an injury, additional booster shots could be given.

RELEASE OF TOURNIQUETS

To the Editor:—*I still read in first-aid literature that the tourniquet should be released every 20 minutes. In my intern days I remember tourniquets being applied to the legs for well over an hour in orthopedic operations. What is the proper recommendation as to the length of time the tourniquet should be placed on a limb without ill-effect to that limb?*

Paul W. Hughes, M.D., Fort Lauderdale, Fla.

Answer.—While the time-honored first-aid recommendation that a tourniquet be released for a few seconds every 20 minutes is firmly entrenched in first-aid literature, undoubtedly it has no basis on actual experimental findings. It is merely an opinion that has become incorporated firmly in a certain type of literature. The writer has been interested in this subject, and it is his opinion that the time intervals recommended by surgeons queried on this matter tend to be conservative and that in their own actual experience they have left tourniquets on much longer than the recommended time without any damage. Most of them will admit this on persistent questioning. The writer has many times left a tourniquet on an extremity for 90 minutes and occasionally up to two hours, without apparent harm. Even though most of the time limits recommended for tourniquet use are based on clinical experience, certain theoretical considerations have a bearing on the matter, particularly those concerned with the character of the tourniquet in its relation to local tissue damage from pressure and the temperature conditions under which the tourniquet is used. This last is probably the most important single factor affecting the length of time that a tourniquet can be left on without risk of permanent injury. If a tourniquet constricts an extremely narrow band of tissue it may do harm through direct trauma to the local tissues and particularly to the blood vessels. This possibility is enhanced greatly if atheromatous plaques are present in a patient with advanced arteriosclerosis. The actual pressure exerted by a rubber tube type or Esmarch bandage type of tourniquet may be great if used by inexperienced individuals. The various pneumatic tourniquets, using a pressure gauge of some type, usually cover a much wider band of tissue, do not exert excessive pressures, and are therefore much safer. Temperature level has a marked effect on the survival of tissues. It is probable that a tourniquet, applied to an extremity in an air-conditioned room where the extremity is permitted to cool several degrees after the application, could be left on for a much longer time. Experiences with refrigeration anesthesia suggest the probability that if an extremity is properly cooled a tourniquet may be left on for several hours without irreversible tissue damage. Probably there is a direct proportion between the temperature maintained in the extremity (down to freezing) and the length of time the tourniquet may be safely left in place. Since tourniquets may be applied in emergency by relatively inexperienced individuals, under conditions of extreme high temperature on certain occasions, and since a very temporary release of a tourniquet can do no particular harm, it would seem that the 20 minute limitation recommended in first-aid literature is probably a safe rule for over-all general use, under first-aid conditions.

BRADYCARDIA DURING ANESTHESIA

To the Editor:—*A 58-year-old man with a preoperative blood pressure of 122/70 mm. Hg and a pulse rate of 64 underwent cholecystectomy and appendectomy under endotracheal cyclopropane-anectine drip anesthesia. Early in the operation, following exploration of the abdomen and traction on the liver and on the gallbladder, there was a period of bradycardia (pulse rate 36 to 40) and hypotension (systolic blood pressure 60 to 70 mm. Hg). After changes in level of anesthesia, changes in anesthetic agent, and increased ventilation proved ineffective, a pulse rate of 60 and a blood pressure of 110/70 mm. Hg were restored after intravenous administration of 1/200 grain (0.3 mg.) of atropine. Total period of bradycardia and hypotension was about 10 minutes. 1. Does this patient have an increased risk of postoperative coronary thrombosis or cerebrovascular accident? 2. Would nasal administration of oxygen for 24 hours postoperatively have prophylactic value against coronary thrombosis and/or cerebrovascular accident? 3. What other management would be suggested?*

Aviva S. Hoyer, M.D., Los Angeles.

Answer.—1. There is no reason to believe that fainting, which causes profound bradycardia and hypotension, or a similar vagal episode during anesthesia and laparotomy, will predispose to coronary thrombosis or cerebrovascular accident either during or after the episode. 2. The administration of oxygen after a fainting episode is not necessary and probably would be ineffective as prophylaxis for impending cerebral or cardiac accidents due to any cause. 3. No medicament other than atropine seems necessary in a case of this sort.

DIAGNOSIS OF CELIAC DISEASE

To the Editor:—*Please outline the differential diagnosis of celiac disease, including the essential points in laboratory diagnosis and the newer concepts in the etiology, treatment, and management.*

M.D., Canada.

Answer.—Idiopathic celiac disease is a chronic nutritional disorder of children characterized by abdominal distention and associated with diarrhea with large, pale, greasy, foul-smelling stools. Idiopathic celiac disease, in which causal factors are not clearly defined, must be differentiated from cystic fibrosis of the pancreas and obstructive, short-circuiting, and chronic inflammatory lesions of the intestine, among which may be malrotation of the intestine, gastrocolic fistula, regional ileitis, chronic giardiasis, and abdominal tuberculosis. Idiopathic celiac disease is essentially a disorder of intestinal assimilation, in contrast to cystic fibrosis of the pancreas in which the difficulty concerns enzymatic digestion of foods rather than assimilation. The explanation of the assimilatory defect is still obscure. Two

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

factors seem to be present, a constitutional peculiarity that renders these patients peculiarly susceptible to a trigger mechanism, which is usually a parenteral infection or in some cases psychic trauma. In making the differential diagnosis roentgen examinations of the gastrointestinal tract excludes various conditions associated with partial or intermittent obstruction. Chronic enteric infections are ruled out by bacteriological studies. The chief problem is differentiating from cystic fibrosis of the pancreas. In idiopathic celiac disease the onset is rarely under six months, and there is a tendency to spontaneous recovery. Furthermore the duodenal enzymes are normal, while in pancreatic disease they are all very low. The serum proteins are usually reduced, while in pancreatic disease they are usually normal. Digestion of gelatin film by stool is usually positive, and the glucose tolerance test is flat, while in pancreatic disease the former is negative and the latter often normal. The amino acid absorption is normal in celiac disease, while in pancreatic disease the curve is flat. Absorption of vitamin A given in alcohol is impaired in celiac disease, while it is normal in cystic fibrosis of the pancreas. Probably the simplest and most reliable tests are the duodenal enzyme determinations, glucose tolerance test, and vitamin A absorption. X-ray examinations are also of great help. In idiopathic celiac disease there is a persistence of the infantile clumping pattern, while in pancreatic disease this is usually absent. The demonstration of latent infection or parasitic infestation is not infrequently found in celiac disease. Treatment consists mainly of maintaining the patient's nutrition. Dietary measures vary, and it is generally agreed the diet should be high in protein. Most clinicians favor the restriction of fat. The tendency in recent years has been to feed the simple sugars and to avoid polysaccharides of high molecular weight. Vitamins should supplement the diet. Anemia, when present, should be treated with iron. Drugs play little part in therapy except in eradicating infection.

DETERMINING THYROID STATUS

To the Editor:—*In a patient who is taking 1 or 2 grains (6 or 13 mg.) of thyroid per day, is there any way of determining the true thyroid status, other than stopping the medication and waiting three months and then doing radioiodine uptake, protein-bound iodine, and/or basal metabolism tests?*

Ephraim M. Katz, M.D., Bronx, N. Y.

Answer.—A simple method has been described by (Jeffries, W. K., and others: Value of Single Injection of Thyrotropin in Diagnosis of Obscure Hypothyroidism, *New England J. Med.* 249:876-884 [Nov. 26] 1953), utilizing the stimulating effect of thyroid-stimulating hormone in the thyroid gland. On the first day a tracer dose of radioactive iodine (I^{131}) is administered and the thyroid uptake determined after three hours. On the next day the residual I^{131} in the thyroid gland is estimated, a second tracer dose is administered orally along with 10 mg. of thyroid-stimulating hormone administered intramuscularly and a second three-hour uptake is determined. The ingestion of thyroid does not prevent a response to the injection of thyroid-stimulating hormone. If a primary hypothyroidism exists there will be no response to thyroid-stimulating hormone. If the hypothyroidism is secondary to pituitary deficiency there will be a sharp increase in the uptake on the second day. If the patient is euthyroid and receiving thyroid medication, there will be an increase in uptake similar to that of a euthyroid individual without medication. If the patient is hyperthyroid and is receiving desiccated thyroid little suppression of thyroid uptake will be found with the control test. In euthyroid individuals thyroid medication of 1 grain (6 mg.) or more suppresses uptake. (Greer, M. A., and Smith, G. E.: Method for Increasing Accuracy of Radioiodine Uptake as Test for Thyroid Function by Use of Desiccated Thyroid, *J. Clin. Endocrinol.* **14**:1374-1384 [Nov.] 1954). An elevation of protein-bound iodine following thyroid-stimulating hormone can be used in a similar manner as I^{131} uptake. The technique of the thyroid-stimulating hormone test has not been standardized. Some make use of a six hour uptake, others use a 24 hour uptake, and others use several injections daily for one or more days (Schneeberg, N. G., and others: Diagnosis of Equivocal Hypothyroidism Using Thyrotropic Hormone (TSH), *J. Clin. Endocrinol.* **14**:223-231 [Feb.] 1954), determine the 24 hour thyroid uptake and approximately two weeks later repeat this procedure following three daily consecutive intramuscular injections of 20 to 30 mg. of thyroid-stimulating hormone. This method gives greater percentage increases in thyroid uptake and is perhaps more accurate but is more troublesome. Thyroid-stimulating hormone is obtained from Armour Laboratories under the name of Thytropar in 10 U.S.P. units per ampul. Four units is equal to 2.5 mg. of thyroid-stimulating hormone, as reported in the literature.

DYSMENORRHEA

To the Editor:—*Please outline the therapy for an adolescent with dysmenorrhea. Need any differential diagnosis be entertained in a girl who is menstruating and suffers severe lower abdominal pain at the same time?* *M.D., Massachusetts.*

Answer.—Differential diagnosis is definitely indicated. This consultant proceeds with the following treatment: (1) careful physical examination and pelvic examination and careful examination of the posterior fornix to detect migrating, developing endometrial cysts; (2) diagnostic dilation, curettage, and transtubal insufflation by the method of Rubin to determine if there is tubal obstruction that is confined to the lumen and is making it impossible to diagnose by bimanual examination; and (3) if there is definite retroversion or retrocession with descensus, a Smith-Hodge pessary inserted and worn by the patient several months to determine if the position of the uterus causes the pain. If a definite diagnosis of primary, or essential, dysmenorrhea has now been established, the following is the therapeutic procedure. A detailed outline of the problem of menstruation is discussed with the patient. The fact that the condition is more severe in the nervous type with a low threshold of pain is emphasized. The need of exercise for building of the body is also emphasized, as many of these people are of sedentary habits. Emphasize the fact that there is no real change in the organism and no definite proof that there is an alteration in estrogen or progestogens as causative factors. In regard to medication and treatment, the following are given: (1) encouragement; (2) aspirin, Bufferin, or Anacin; (3) bed rest not encouraged; (4) hot water bag—some patients prefer cold water bags; (5) mild sedation (Acetanilid is supposed to be quite efficient. Morphine derivatives and alcohol should be absolutely prohibited); (6) substances containing benzedrine may be helpful; (7) estrogenic substances may be of value by stopping ovulation as shown by Kurzrock (it is known that pain does not occur with an ovulatory cycle); and (8) finally dilation and curettage may be done and repeated if necessary. If all of these are of no avail one must consider an operation that includes a good suspension of the uterus with plication of the uterosacral ligaments and painstaking sacral neurectomy; the latter at times is quite efficient. Severe dysmenorrhea is infrequent. If pain persists throughout the period and is of a dull heavy nature it is most likely secondary; the primary type is spasmodic; labor-like pains prior to the onset of the flow, and when the flow is established the pain is relieved.

HYPOTHETICAL VENEREAL DISEASE QUESTION

To the Editor:—*As a hypothetical question let us assume that a naval ship puts into ports where the sailors all go on leave after a long time at sea. Would a substantial injection of penicillin protect these men against venereal disease?*

M.D., Nebraska.

Answer.—In theory, it would be possible to protect a ship's company about to go on shore leave for four or five days against the acquisition of syphilis and gonorrhea (but not of lymphogranuloma venereum or granuloma inguinale) by the intramuscular injection of 600,000 units of a repository penicillin preparation given at the time the sailor leaves the ship. Such protection would probably last only for the specified period of four to five days and no longer. In practice, however, this is both a visionary and an intolerable suggestion. It would involve the administration of penicillin to a great many men who do not propose to expose themselves to venereal disease, and who would, therefore, rightfully object to the procedure. It would involve, moreover, the medicolegal issue of the invasion of the sanctity of the person by means of a surgical instrument (a needle) carried out without the patient's consent. Such a procedure would, moreover, be indefensible on moral grounds and would be opposed, not only by the Chaplain's Corps but also by medical and command officers. On the other hand, penicillin administered orally after exposure in a dose of 250,000 units is highly effective in the prophylaxis of gonorrhea, provided the penicillin is taken within one hour of the suspected exposure. There is some degree of protection for as long as 12 hours after exposure. The use of orally given penicillin for the prophylaxis of syphilis is probably ineffective, since repeated doses over a period of several days and to a total of several million units would be necessary.

CATARACT

To the Editor:—*In a case of posterior cupuliform cataract (posterior subcapsular or saucer type) if one would do a planned extracapsular extraction, and remove all of the anterior capsule at the time of surgery, would the patient need a capsulotomy later? In other words, does the posterior cupuliform opacity affect the posterior capsule of the lens, making it opaque and necessitating a secondary operation (capsulotomy) or is the opacity truly subcapsular as the name implies?*

M.D., Pennsylvania.

Answer.—The cupuliform cataract involves posterior cortical region, and the posterior capsule is not included. However, since other portions of the lens frequently participate in opacification with cupuliform cataract involvement of the posterior capsule would not be unusual. This type of lens responds nicely to extracapsular extraction and there is surprisingly little cortex. However, there can be no assurance that a subsequent needling will not be required.

SULFONAMIDES AND SODIUM BICARBONATE

To the Editor:—*In* The Journal, *Feb. 26, 1955, in Queries and Minor Notes, page 780, a question on the use of sodium bicarbonate with sulfonamides for systemic administration was answered, and no mention was made of the widely used sulfonamide mixtures such as the sulfapyrimidines (sulfadiazine, sulfamerazine, and sulfamethazine). The answer inferred that only with sulfanilamide and sulfisoxazole is one reasonably sure of freedom from crystalluria without concomitant administration of alkali. The danger of crystallization depends on the amount of sulfonamide administered, in addition to solubility. When combinations of sulfonamides are used, the likelihood of crystallization depends not on the total dosage but on the amount of each single component in the mixture. The evidence for diminished crystalluria with the use of sulfonamide mixtures has been well documented.* Lehr (Proc. Soc. Exper. Biol. & Med. **58:***11, 1945; ibid.* **64:***393, 1947;* J. A. M. A. **139:***398, 1949;* Brit. M. J. **2:***601, 1950) has published experimental and clinical experiences in several reports in the English literature since 1945 and has shown that administration of combined sulfonamides without adjuvant alkalinization has given rise to low incidence of crystalluria. Frisk, Hagerman, and co-workers* (Nord. med. **29:***639, 1946) reported similar results in the Scandinavian literature. Flippin and Reinhold* (Ann. Int. Med. **25:***433, 1946) using mixtures of sulfadiazine and sulfamerazine without adjuvant alkali reported considerably less crystalluria than when single sulfonamides were administered.*

No case of renal obstruction due to these triple sulfonamides has been documented in the literature, despite the fact that multiple sulfonamides have been widely prescribed for years in the United States. It may be that the relatively obsolete sulfonamides, such as sulfanilamide and sulfapyridine, were included in the discussion and sulfonamide mixtures were ignored because the inquiry originated in India, where triple sulfonamides are not widely available. However, the above is submitted to set the record straight for the American and Canadian reader.

SNAKE BITE

To the Editor:—*In* The Journal *for July 30, 1955, page 1235, an inquirer is given a description of Dr. Stahnke's excellent "L-C" treatment for snake bite. Dr. Stahnke's publication of this technique for patients gives credit to my animal experiments that established the principle. Presumably ethyl chloride is recommended because it might be carried on trips, where ice could not be carried. If ice is obtainable, even before a bucket is found, Dr. Stahnke would probably agree that direct application of ice to the area is best. Incisions may be added in dangerous cases. Besides my experimental publications, I have urged this treatment for snake, spider, scorpion, wasp, or other poisoned wounds (even mosquito bites) in two letters* (J. A. M. A. **139:***616 [Feb. 26] 1949; ibid.* **151:***1156 [March 28] 1953). Two other answers to inquiries* (J. A. M. A. **150:***1549 [Dec. 13] 1952; ibid.* **153:***178 [Sept. 12] 1953) prescribed treatments, omitting refrigeration. This was particularly unfortunate in the recommendation for coral snake bite, which on theoretical grounds should respond excellently to cold, though it is otherwise painful and dangerous.*

Annual deaths from snake bite are estimated at 25,000 to 35,000 for Asia, 3,000 for South America, 300 to 500 for North America including Mexico, smaller numbers for Europe, and large unknown numbers for Africa. Ninety-five per cent of the bites are on limbs. It should be made known that not a single death from these bites is necessary. Assuming that a bite is judged to be fatal, for example, that somebody in a wilderness remote from any therapeutic aid is bitten by the largest bushmaster or king cobra, my experiments showed that it is always possible to save life at the cost of a limb by promptly applying a tight permanent tourniquet. Amputation can then be deferred for a day or two if necessary. Such a tourniquet is very painful for several hours, but so is the snake bite. A tight tourniquet should never be applied without refrigeration unless the limb is to be sacrificed. With refrigeration, Dr. Stahnke wisely limits the tourniquet to five minutes, then the refrigeration alone is continued for a selected number of hours.

To the Editor:—*Having seen the answer to a question on snake bite in* The Journal, *July 30, 1955, page 1235, I am prompted to offer a few comments. The L-C method proposed by Herbert L. Stahnke, Ph.D., professor of zoology and director of the poisonous animals research laboratory, Arizona State College, was ably discussed by Dr. Frederick Shannon at the first International Conference on Venoms, in Berkeley, Calif., in December, 1954. His paper, with the others read at the conference, is now in press, to be published in a symposium volume under the title "Venoms." His findings were in agreement with the brief description given in the answer.*

Although it is true, as stated by your consultant, that "tourniquet, multiple incision, and suction technique following the head of swelling is still the local treatment of choice" in Crotalus envenomization, he neglected to mention the importance of neutralizing the venom received in the bite with specific serum. Especially in severe envenomization by crotaline species, when it is impossible to remove sufficient venom by purely mechanical measures, is it imperative to administer an adequate dose of antivenin at the earliest moment. As pointed out by other contributors to the conference, the venoms of crotalids break down the blood vessels; thus permeation of the body by the serum may be impeded if specific treatment is delayed. Incisions on a digit are lawways contraindicated, since, as emphasized by Dr. Shannon, the trauma of a knife blade increases tissue damage and may be responsible for ultimate gangrene, necessitating amputation.

MANAGEMENT OF DIABETES MELLITUS DURING KETOACIDOSIS, ACUTE INFECTION, AND SURGERY

Joseph I. Goodman, M.D., Cleveland

The three commonest acute complications in diabetic patients are ketogenic acidosis, acute infection, and surgical or traumatic events. It will be shown in this paper that the underlying pathological physiology is the same regardless of which condition prevails. With this concept in mind, the management of these diabetic complications is greatly simplified. A regimen is presented that is based on the physiological mechanism of ketogenesis and applicable to any of these complications.

CAUSES OF DIABETIC ACIDOSIS AND COMA

Mechanism of Ketogenesis.—Results of experimental studies during the past decade have altered the concept of ketone formation, and ketones are no longer considered abnormal metabolites. The evidence favors the theory that ketones are normal end-products of fat catabolism and are made in significant quantities solely in the liver whence they are distributed to the blood. A liver rich in glycogen will supply no more ketones than the body can use. Under physiological conditions glucose is used preferentially by the body as a source of energy. Like glucose, the ketone bodies can be utilized as a readily available body fuel by the muscles and all other tissues except the central nervous system. The ketone formed in largest amounts is β-hydroxybutyric acid ($CH_3CHOHCH_2COOH$). Acetoacetic acid (diacetic acid, β-oxybutyric acid, or CH_3COCH_2COOH) results from oxidation of β-hydroxybutyric acid, and acetone (CH_3COCH_3) is produced by the breakdown of acetoacetic acid. Apparently acetoacetate may enter into the tricarboxylic acid cycle, one of the steps through which glucose is converted into energy for muscle contraction.[1]

When the diet is deficient in carbohydrate, ketone substances are formed from the body stores of fat and amino acids appear in the blood in increasing amounts. In the normal adult the minimum limit of glucose utilization below which ketogenesis is likely to occur is roughly 50 to 100 gm. daily. When the total amount of glucose utilized exceeds these limits, ketosis cannot occur unless the total metabolism is increased. To capitulate, when exogenous glucose intake is sufficiently limited in quantity, ketogenesis takes place in the following steps: Inadequate glucose intake leads to inadequate glucose utilization, which leads to increased fatty acid mobilization and then to increased production of β-hydroxybutyric acid, acetoacetic acid, and acetone.

Diabetic Ketosis.—When the production of ketone bodies exceeds the ability of the tissues to oxidize them, as in uncontrolled diabetes, they accumulate in the blood and are excreted by the kidneys into the urine. The accumulation of ketone bodies in the blood is known as ketonemia or ketosis, while their presence in the urine is called ketonuria. These organic ketoacids (ketones) combine with base in tissue fluids to form salt and, most important, deplete the alkali reserve of the body. The loss of base causes a marked reduction in the carbon dioxide combining power of the blood plasma and loss of fluids; the latter further intensifies the acidosis, setting up a vicious cycle. It is obvious that, if ketogenesis is unchecked, more and more base will be lost, resulting in the familiar picture of advanced ketogenic acidosis.

The terms ketosis and acidosis are not synonymous. Ketosis is more descriptive than coma, which suggests unconsciousness, or acidosis, which is in essence a secondary manifestation of the condition. A state of ketosis may develop in either diabetes mellitus or starvation, but acidosis need not be a concomitant. However, the acidosis of diabetes is due invariably to excessive ketogenesis. Mirsky's[2] interpretation of experimental facts appears to indicate that a decrease in liver glycogen is the stimulus for an increase in the production of fatty acids. When the demand for fat exceeds 2.5 gm. per kilogram of body weight per day, the production of ketones exceeds their utilization and, if unchecked, leads to ketosis. Stadie's[3] demonstration that fats are the chief source of ketones lends support to this hypothesis.

Stress Factors.—In normal man and animals trauma and other stresses are often followed by glycosuria and reduced tolerance to glucose. It is well known that sanctity of the person by means of a surgical instrument (a needle) carried out without the patient's consent. Such a procedure would, moreover, be indefensible on moral grounds and would be opposed, not only by the Chaplain's Corps but also by medical and command officers. On the other hand, penicillin administered orally after exposure in a dose of 250,000 units is highly effective in the prophylaxis of gonorrhea, provided the penicillin is taken within one hour of the suspected exposure. There is some degree of protection for as long as 12 hours after exposure. The use of orally given penicillin for the prophylaxis of syphilis is probably ineffective, since repeated doses over a period of several days and to a total of several million units would be necessary.

MANAGEMENT OF DIABETES MELLITUS DURING KETOACIDOSIS, ACUTE INFECTION, AND SURGERY

Joseph I. Goodman, M.D., Cleveland

The three commonest acute complications in diabetic patients are ketogenic acidosis, acute infection, and surgical or traumatic events. It will be shown in this paper that the underlying pathological physiology is the same regardless of which condition prevails. With this concept in mind, the management of these diabetic complications is greatly simplified. A regimen is presented that is based on the physiological mechanism of ketogenesis and applicable to any of these complications.

CAUSES OF DIABETIC ACIDOSIS AND COMA

Mechanism of Ketogenesis.—Results of experimental studies during the past decade have altered the concept of ketone formation, and ketones are no longer considered abnormal metabolites. The evidence favors the theory that ketones are normal end-products of fat catabolism and are made in significant quantities solely in the liver whence they are distributed to the blood. A liver rich in glycogen will supply no more ketones than the body can use. Under physiological conditions glucose is used preferentially by the body as a source of energy. Like glucose, the ketone bodies can be utilized as a readily available body fuel by the muscles and all other tissues except the central nervous system. The ketone formed in largest amounts is β-hydroxybutyric acid ($CH_3CHOHCH_2COOH$). Acetoacetic acid (diacetic acid, β-oxybutyric acid, or CH_3COCH_2COOH) results from oxidation of β-hydroxybutyric acid, and acetone (CH_3COCH_3) is produced by the breakdown of acetoacetic acid. Apparently acetoacetate may enter into the tricarboxylic acid cycle, one of the steps through which glucose is converted into energy for muscle contraction.[1]

When the diet is deficient in carbohydrate, ketone substances are formed from the body stores of fat and amino acids appear in the blood in increasing amounts. In the normal adult the minimum limit of glucose utilization below which ketogenesis is likely to occur is roughly 50 to 100 gm. daily. When the total amount of glucose utilized exceeds these limits, ketosis cannot occur unless the total metabolism is increased. To capitulate, when exogenous glucose intake is sufficiently limited in quantity, ketogenesis takes place in the following steps: Inadequate glucose intake leads to inadequate glucose utilization, which leads to increased fatty acid mobilization and then to increased production of β-hydroxybutyric acid, acetoacetic acid, and acetone.

Diabetic Ketosis.—When the production of ketone bodies exceeds the ability of the tissues to oxidize them, as in uncontrolled diabetes, they accumulate in the blood and are excreted by the kidneys into the urine. The accumulation of ketone bodies in the blood is known as ketonemia or ketosis, while their presence in the urine is called ketonuria. These organic ketoacids (ketones) combine with base in tissue fluids to form salt and, most important, deplete the alkali reserve of the body. The loss of base causes a marked reduction in the carbon dioxide combining power of the blood plasma and loss of fluids; the latter further intensifies the acidosis, setting up a vicious cycle. It is obvious that, if ketogenesis is unchecked, more and more base will be lost, resulting in the familiar picture of advanced ketogenic acidosis.

The terms ketosis and acidosis are not synonymous. Ketosis is more descriptive than coma, which suggests unconsciousness, or acidosis, which is in essence a secondary manifestation of the condition. A state of ketosis may develop in either diabetes mellitus or starvation, but acidosis need not be a concomitant. However, the acidosis of diabetes is due invariably to excessive ketogenesis. Mirsky's [2] interpretation of experimental facts appears to indicate that a decrease in liver glycogen is the stimulus for an increase in the production of fatty acids. When the demand for fat exceeds 2.5 gm. per kilogram of body weight per day, the production of ketones exceeds their utilization and, if unchecked, leads to ketosis. Stadie's [3] demonstration that fats are the chief source of ketones lends support to this hypothesis.

Stress Factors.—In normal man and animals trauma and other stresses are often followed by glycosuria and reduced tolerance to glucose. It is well known that physical stresses likewise increase the hyperglycemia of persons with diabetes mellitus.[4] It has been suggested that the "aggravation of diabetes" with infections, fractures, and other types of stress is due to increased adrenal activity and consequent overproduction of glucocorticoids.[5]

---

[1] Soskin, S., and Levine, R.: Carbohydrate Metabolism: Correlation of Physiological, Biochemical and Clinical Aspects, Chicago, University of Chicago Press, 1946, p. 53.

[2] Mirsky, I. A.: The Etiology of Diabetic Acidosis, Proc. Am. Diabetes A. 1: 51-68, 1941.

[3] Stadie, W. C.: Fat Metabolism in Diabetes Mellitus, Ann. Int. Med. 15: 783-797 (Nov.) 1941.

Clinicians have long noted, and the viewpoint is still expressed, (1) that "breaking of diet" and the ingestion of large quantities of carbohydrate may induce ketosis, and (2) that persons with diabetes often are admitted to the hospital in coma after an "eating spree." Mirsky, Franzblau, and co-workers [6] and others [7] have demonstrated conclusively that patients do not develop ketosis merely because of dietary indiscretions. It appears, therefore, that simple ingestion of food cannot cause ketosis, that diabetic persons do not "eat themselves into coma," but that rather, when subjected to stress, they respond with ketonemia, diuresis, and an increased ingestion of food.[8]

In extended clinical studies in diabetics Hinkle and associates [8] have observed repeatedly that cases of ketosis and coma show not only an intimate temporal correlation with significant events in the lives of the patient but also changes in carbohydrate tolerance. In adolescents instances of ketosis have been seen to develop within a relatively few hours after a severe conflict, quite in the absence of infections or of significant changes in the diet or insulin intake. Dolger observed an adolescent girl on a hospital ward who, in a conflict situation, developed severe ketosis within six hours requiring over 400 units of insulin for its treatment.

Precipitating Causes of Diabetic Ketogenesis.—The direct precipitating cause of diabetic ketogenesis is loss of appetite. The diabetic is not immune to conditions that cause nausea and vomiting such as gastrointestinal upsets, appendicitis, and acute infections, especially renal infections. Because prolonged vomiting often results in ketogenesis, potentially any of these conditions can precipitate coma. Essentially this is a form of starvation ketosis. One is forced to conclude that vomiting is an evil omen in diabetes and unless heeded may lead to death.[9] It is remarkable how frequently the uneducated, unprepared diabetic patient, unable to take food during an acute complication because of anorexia, omits his insulin. In the later stages of ketosis, after symptoms begin, the danger is vastly increased and treatment is much more difficult. In short, the anorexic diabetic patient is a potential emergency at all times, but when vomiting is associated with some other disorder, such as an upper respiratory tract infection or a gastrointestinal upset, a serious emergency exists.

Treatment of Ketosis.—Preventive therapy will obviate the necessity of treating severe ketosis. Prevention begins with well-educated diabetic patients being schooled particularly against the fallacy of stopping food and insulin when they feel ill, have a fever, or lose their appetite. The patient should know that in the anorexic phase of infection insulin must not be omitted and food intake should not be materially reduced. Adequately trained diabetic patients will always regard loss of appetite, with or without nausea, as a danger signal concerning the correction of which their physician should be consulted immediately.

In active treatment of diabetic ketosis the pathological physiology should be borne in mind and measures designed to reverse these mechanisms instituted promptly and pursued vigorously. Once ketogenesis becomes excessive, the chief principle of therapy, and the most effective way of suppressing it, is the encouragement of glycogenesis. As long as glycogen is available, the need for fatty acids is reduced and excessive ketogenesis is unlikely. How does one induce glycogen deposition in the liver and thus reduce the stimulus for ketogenesis? In starvation the mere ingestion of food, principally carbohydrate, will arrest excessive ketogenesis. Carbohydrate will also retard ketone formation in diabetes mellitus. Insulin prevents the glycogen so stored from being dissipated rapidly. Mirsky [10] has shown a drop in the ketone concentration of the blood and urine in dogs whose pancreas glands have been removed after the administration of glucose by vein; excessive quantities of carbohydrate fed to a diabetic patient also decreased ketone formation. Root and Carpenter [11] reported a drop in the blood ketones from 70 to 44 mg. per 100 cc. in a diabetic patient three hours after 50 gm. of glucose was given intravenously. Mattar [12] studied the effects of glucose administration on ketosis in three diabetic patients. During the five day observation period the blood ketones were lowered in each patient, the actual fall being from 28 to 17, 36 to 19, and 41 to 25 mg. per 100 cc. respectively. If vomiting persists, 5 or 10% glucose solution should be given continuously intravenously until the patient is able to retain food for several hours by the oral route.

MANAGEMENT DURING ACUTE COMPLICATIONS

All the acute complications of diabetes—ketogenic acidosis, acute infection, surgical procedures, or traumatic events—can be treated by the same method, the exact treatment varying only in detail. Tolstoi permits unrestricted glycosuria providing there is no acetonuria. Some authors give the entire daily insulin requirement preoperatively, others give only a portion, and Barach gives none except postoperatively. Shapiro gives protamine zinc insulin whereas Duncan and others suggested equally divided feedings and regular insulin, as in the following regimen.

The program that has received the most widespread adoption was devised by Woodyatt shortly after the discovery of insulin and has been used by many of his adherents. The method utilizes equally divided feedings and multiple doses of regular insulin. Each day is divided into four six-hour periods. An injection of unmodified insulin is given at the beginning of each period. An oral or parenteral feeding, equal in glucose value to that given in each of the other periods, is given at the beginning of or during the period. Duncan recommends a daily diet that contains 115 gm. of protein, 250 gm. of carbohydrate, and enough fat to bring the calorie total to 30 to 35 calories per kilogram of body weight; the diet is divided so that the caloric intake for each period is equal. The diet can be served also in soft or liquid form. When a patient is unable to retain feedings by mouth or tube, an intravenous program patterned on the six hour schedule outlined above is used. Administration of a new bottle of glucose is started every six hours and insulin injected subcutaneously as each bottle is begun.

In very rare instances, where several hundred units of insulin are given in each 24 hours, the diet is divided into six equal meals given every four hours. The insulin dosage is determined by urinalysis as in the four-meal program. A urine specimen is collected after each six hour period and tested for sugar and acetone, the result determining the next insulin dose. The insulin dose should be sufficient to prevent acetonuria. Insulin given more frequently tends to overlap to the extent that the effect of any given dose is difficult to judge. If given at much longer intervals, the effect fails to overlap at all and control is lost quickly. The proponents of this method believe that control is maintained more easily with regular insulin than with modified insulin.

Prevention and Treatment of Ketoacidosis.—A person with severe diabetes must, without exception, be maintained under the continuous effect of insulin. This can be accomplished only when his daily insulin is taken regularly. It is absolutely essential that the usual insulin dose is not discontinued during periods of abnormal stress such as a gastrointestinal upset, or any other disturbance that impairs ingestion of food. It is my policy to continue the patient's usual insulin dosage, unaltered in any manner, throughout the entire course of all illnesses (infection, surgery).

Ketonuria is a sufficiently accurate guide to therapy and can be easily evaluated at the bedside. Tests made every two or three hours usually show the trend of the ketonuria, but one can examine every specimen of urine voided. Blood sugar analysis is not very helpful in the management of ketoacidosis, since the results are not available rapidly enough to be of aid. Besides, when glucose is being given intravenously, blood sugar values are useless and may be misleading while intravenous glucose is being given. Glucose therapy would be a definite hindrance if the treatment of ketoacidosis and coma were based on the blood sugar determinations. However, one must not permit the true aim of therapy, namely, arrest of ketogenesis and not lowering of the blood sugar level, to be obscured by all the arguments pro and con the use of glucose.

Illness That Prevents Oral Feeding: Evidence has been cited to prove that carbohydrate is the best antidote for the suppression of ketogenesis. This is the goal in the treatment of ketoacidosis in my patients. If the patient is able to eat, frequent small carbohydrate feedings are ordered every one to two hours throughout the 24 hour period. For those who are vomiting, or unable to take food by mouth, 5 to 10% glucose in water is administered continuously by vein and maintained until it is clearly shown that the patient is able to retain food orally. If oral feedings cannot be retained by a diabetic patient because of vomiting, or for any reason, then parenteral administration of 5 or 10% glucose solution, subcutaneously or intravenously, should be maintained continuously. Nine grams of salt is the normal requirement in each 24 hours, but the need is several times this amount during ketoacidosis and may be supplied by isotonic sodium chloride solution. The total amount of fluid administration should be adequate to maintain the urine volume above 1,000 cc.

Feedings.—Diabetic patients should not be permitted to go without food for more than a few hours. In emergency situations the diet should be planned in principle primarily to thwart starvation ketosis. Feedings may be given in small meals, soft or liquid, by hypodermoclysis or venoclysis, whichever method is indicated at the time. A menu comprised of carbohydrate in the form of oatmeal or other cereals, fruit juices, well-cooked or pureed vegetables, protein such as eggs, fish, and chicken, and fat in the form of cream will tide a patient over many emergencies. The feedings should be taken every one to two hours day and night. The normal diet should be put into effect just as soon as his condition permits.

Absolute aglycosuria is not necessary, or indeed wholly desirable, during the short period of acute infections since recovery may begin at any time. Joslin's views [9] on this point cannot be overemphasized, viz., that an overvigorous attempt should not be made to get the patient sugar-free during infections and either before or after operation. Where hypoglycemia imposes a serious risk, as in myocardial infarction, glycosuria need not be an indication for increased insulin dosage.

SOME CONSIDERATIONS OF ACUTE INFECTIONS IN DIABETES

The explanation of the unfavorable effect of infections on diabetes is not known, but those causing fever and leukocytosis appear to disturb carbohydrate metabolism most markedly. Williams and Dick found glycosuria in 41% of nondiabetic patients with acute infectious diseases, the largest average amounts occurring with influenza. Labbé [13] demonstrated a lowered carbohydrate tolerance in pneumonia, and MacLean and Sullivan [14] in encephalitis, tuberculosis, meningitis, and measles. The behavior of the diabetes, favorable and unfavorable, is frequently a reliable index of the trend of an infectious process.

Duncan suggests that lowered carbohydrate tolerance during infections, either in the diabetic or the nondiabetic, theoretically might be due to one of four causes:

---

13. Labbé, M., and Boulin, R.: Disturbances of Glucose Regulation During Infections, Bull. et mém. Soc. Med. hôp. Paris 49: 1358-1368 (Oct. 30) 1925.

14. MacLean, A. B., and Sullivan, R. C.: Dextrose Tolerance in Infants and in Young Children, Am. J. Dis. Child. 37: 1146-1160 (June) 1929.

(1) lessened production of endogenous insulin; (2) increased production of hormonal antagonists; (3) destruction of insulin; or (4) interference with the storage and utilization of glycogen. Of these, it seems to me that the excess production of the adrenal ketosteroid is the most likely mechanism during acute infection.

Diarrhea.—Diarrhea in diabetic patients is a serious, distressing complication, particularly when accompanied by vomiting. With abstinence from food, patients with diarrhea often reason erroneously that they should not take any insulin. Since gluconeogenesis and ketogenesis are necessarily increased under conditions of starvation or semistarvation, a predisposition to ketoacidosis, further accentuated by fluid and electrolyte loss, is understandable. Therefore, diarrhea, as well as vomiting, must be regarded seriously in a diabetic.

PRINCIPLES OF SURGICAL MANAGEMENT OF DIABETIC PATIENTS

Since the control of the diabetes may prove to be the most important factor in the total management of the surgical diabetic patient, both the preoperative and postoperative treatment should be carried out on the medical wards. At the Pennsylvania Hospital, for example, a diabetic team consisting of two senior members of the medical staff and one resident physician assumes full responsibility for the management of the diabetes regardless of which service is primarily in charge of the patient. Patients are visited by the resident member at least once daily and at least four times weekly by senior members of the team. All orders for diet, insulin, and other measures pertaining to the diabetes are written by a team member.

There are two main objectives in the medical management of the surgical diabetic: (1) to avoid ketosis and (2) to avoid hypoglycemic reactions. A diabetic can be considered sufficiently controlled to support surgical measures and to have a normal chance of recovery in the absence of ketonuria. Transient glycosuria is a regular occurrence after operation; ketonuria is more serious. More than at any other time it is important to aim for rich glycogen stores in the liver. The patient should go to the operating room well fed, with his liver stocked with glycogen.

Preoperative Preparation.—As the day of operation approaches, the problem of regulating the diabetes immediately before and after surgery presents itself. If there is no need for haste and the diabetes is already under control, no deviation from the former treatment is necessary except to be certain that the patient is fed to within three hours of operation.

Diet: The preoperative diet for the elective surgical patient is in most cases his usual diabetic diet, altered as little as possible, given in three equal meals with a bedtime nourishment containing 10 to 15 gm. of carbohydrate, e. g., a cup of milk and three graham crackers or one slice of bread and butter.

Insulin: Insulin administration preferably should be based on the previously determined requirements of the individual patient. It is advisable to schedule the operation early in the morning so that a long fasting period will be avoided. If the stomach must be empty during the operation, intravenous administration of glucose is started preoperatively. On the morning of surgery I give the entire usual morning dose of insulin (whether regular, intermediate, or long-acting) subcutaneously along with the glucose intravenously.

Postoperative Management.—The postoperative regimen is planned to avoid dehydration and ketogenesis. For this purpose a minimum of 100 to 150 gm. of carbohydrate daily is necessary, any amount not taken by mouth being supplied by parenteral administration in the form of 5 or 10% dextrose solution by vein or 2.5% dextrose in water under the skin. During phases when oral feeding is not allowed, or when the patient is unable to retain fluids, glucose solution, 5 or 10%, should be given intravenously. The protein needs may be satisfied by the administration of amino acids in the same manner, but this is not a critical factor insofar as ketogenesis is concerned. Glucose solutions, administered parenterally, are at best poor substitutes for feedings that the patient cannot take orally.

Perhaps one of the commonest sources of error in the parenteral administration of glucose lies in the assumption that a specific amount of glucose is metabolized by a specific number of units of insulin. In other words, it is assumed that the glucose given intravenously can be "covered" with a standard dose of insulin. In my opinion it is unnecessary and dangerous to attempt to utilize the glucose given intravenously by a calculated dose of insulin. It is even more dangerous to give insulin for the glucose that usually spills over into the urine after an intravenous injection. This is apt to cause hypoglycemia. No serious attempt should be made therefore to render the urine sugar-free postoperatively. The important thing is to render the urine free from ketones.

Tests.—Fractional urine specimens (8 a. m. to 12 noon, 12 noon to 4 p. m., 4 p. m. to 8 p. m., 8 p. m. to midnight, midnight to 4 a. m., and 4 a. m. to 8 a. m.) are tested for acetone and sugar immediately upon the completion of each fraction.

Diet.—In general, the patient should be given a liquid or soft diet as soon as possible after operation. In most cases feeding can begin within four to six hours. Patients having a limb or part of a limb amputated may need no intravenous therapy, and they may sit up six hours after the surgical procedure is terminated. There is no reason for them to miss a meal. Liquid carbohydrate feedings, thin milk, orange juice, ginger ale, and oatmeal water gruel may be instituted three hours after operation and administered freely during the first 24 hours. Except when the nature of the operation necessitates special dietary regulations, liquids such as oatmeal made with water, hot tea, or coffee (with crackers or toast) can be given freely, and ginger ale and orange juice with egg white sparingly on the first postoperative day. As soon as liquids are tolerated by mouth, the equivalent of the former diet is provided. For the first day this diet can be divided into six equal feedings, one being given every four hours.

On the second postoperative day milk and, if the patient desires, cooked cereals, junket, or boiled custard is added to the diet. Finally, when convalescence is well under way—usually in three or four days after operation—the diet employed before the complication is resumed.

Anesthesia.—The less toxic the anesthetic agent, the less it interferes with the patient's dietary routine. Spinal anesthesia with dibucaine (Percaine), heavy solution, is ideal for diabetics and should always be used for amputations and similar operations, as it permits the operation to be performed with a minimum of change in the established preoperative routine. Refrigeration anesthesia has similar advantages but the method is cumbersome. Local anesthesia is also of value in diabetes. Coppleson [15] classifies thiopental (Pentothal) sodium as the most satisfactory general anesthetic agent for use in diabetes and cyclopropane as probably the safest gaseous anesthetic.

Summary of Surgical Management.—This plan of preoperative and postoperative management of the diabetic patient is physiological and has the advantages of simplicity (by the prescription of the patient's regular insulin dose); safety (the feeding schedule and the administration of glucose intravenously is designed to prevent hypoglycemia and ketosis); and convenience (no disruption of medical or nursing service is involved).

COMMENT

The normal ketone level in the blood is rarely in excess of 1 mg. per 100 cc., and the normal urinary excretion is usually less than 500 mg. in 24 hours. In diabetic ketoacidosis, blood ketone levels as high as 368 mg. per 100 cc. and 75 gm. in 24 hour urine specimens have been reported. Koehler, Windsor, and Hill [16] have shown in diabetic subjects that the rate of utilization is such that no ketones accumulate unless fat combustion exceeds approximately 1,650 calories for 24 hours. This means that ketosis is avoided whenever enough carbohydrate is burned so as not to place a demand on fat oxidation for energy to exceed 1,650 calories a day. This concept would seem to eliminate overnutrition as a cause of diabetic coma and substitute undernutrition, that is carbohydrate deficiency, as the real and only dietary cause.[7] When the hepatic glycogen reserve is insufficient to satisfy the full energy requirements, ketosis with its many deleterious accompaniments develops.[10] When diabetic patients undergo formidable operations, glycogenolysis and the difficulties of postoperative alimentation severely drain the previously attained glycogen reserve.

Increased adrenal weight occurs within 6 to 24 hours after the application of a wide variety of stress states and corticotropin administration. Untreated diabetes, especially when associated with ketosis, produces a severe prolonged stimulation of the adrenal cortex sometimes amounting almost to exhaustion. Trauma in nondiabetic man and animals is often followed by glycosuria and reduced glucose tolerance. Moreover, trauma, infections, and other stresses can aggravate a diabetic state.[17] The hyperglycemic reaction to trauma fails to occur in the absence of the adrenals, but a fixed daily dose of adrenal cortical extract, which by itself does not elevate the blood sugar of nontraumatized rats, restores the hyperglycemia of trauma in animals whose adrenals have been removed. The inference from these observations would seem to be that the aggravation of diabetes is due to hyperactivity of the adrenal cortex with consequent overproduction of carbohydrate-active corticosteroids. Similarly, animals without adrenals maintained with a constant daily dose of adrenal cortical extract, which by itself did not cause an increase in nitrogen excretion, exhibited as great an increase in urinary nitrogen excretion after fracture as did normal animals.[18] These observations indicate that the adrenal plays a supportive rather than a causal role in the hyperglycemia, decreased glucose tolerance, and increased nitrogen excretion of stress. Therefore, even though diabetic ketosis is associated with an increased adrenocortical activity, it does not necessarily follow that the aggravation of diabetes that occurs during ketosis is due to adrenal overactivity. Be that as it may, from a nutritional or dietary aspect, the only requirement to avoid ketosis is to have adequate carbohydrate available. It would, therefore, seem rational to supply additional glucose as near as possible to the critical period of glycogen breakdown, ideally, during the operation itself.

Green and his associates studied the relation of delayed healing of clean and infected wounds to the height of the blood sugar level and degree of glycosuria in an impressive number of patients. Even those diabetic patients who revealed considerable postoperative hyperglycemia and glycosuria made uneventful recoveries after a variety of major procedures. Greene's observations [19] demonstrate clearly that postoperative glycosuria does not retard wound healing and, as there was no evidence of infection, the obvious deduction would be that hyperglycemia and glycosuria are not conducive to infection.

SUMMARY AND CONCLUSIONS

The rapidity of onset and the degree of ketosis reached during fasting bears an inverse relation to the protein content of the preceding diet. Apparently ketosis is related to the protein intake preceding the fasting period. The latter serves as a source of antiketogenic material and determines the amount of "stored" protein available for catabolism during fasting. Fasting rats, previously on a high protein intake, maintain their liver glycogen and blood sugar levels better and have a lower level of blood ketone bodies as well. The insulin resistance and higher blood sugar levels during ketosis are probably related to increased adrenocortical activity and consequent overproduction of 11, 17-oxysteroids.

The treatment outlined has been used with excellent results in postoperative diabetics and during acute infections as well. Alimentation with glucose parenterally is advocated during major operations to protect the preoperatively attained glycogen reserve. Finally, it should be pointed out that, when this method of giving glucose covered by insulin and not insulin covered by glucose is used, not only are blood sugar estimations unnecessary but their significance is somewhat questionable.

DEPRESSION AND ANXIETY OCCURRING DURING RAUWOLFIA THERAPY

John C. Muller, M.D., William W. Pryor, M.D., James E. Gibbons, M.D.
and
Edward S. Orgain, M.D., Durham, N. C.

During recent years extracts of Rauwolfia serpentina have been utilized freely in the treatment of hypertensive vascular disease and varied psychiatric illnesses. Initial preparations for clinical investigation were provided only in crude form; but a highly purified alkaloid, reserpine, is now available. In general, the pharmacological properties of the crude and the purified derivatives are essentially the same.[1] These compounds are considered to be free of serious toxic reactions.[2] Mild side-effects frequently encountered are nasal stuffiness, decreased initiative, fatigue, weight gain, drowsiness, nightmares, and diarrhea. These symptoms usually can be relieved by reducing the dosage of the drug without appreciably sacrificing its hypotensive effect.[3] In some patients receiving Rauwolfia preparations in large doses, depression may develop.[4] Although this complication occurs with significant frequency, it has received comparatively little emphasis in the literature. The purpose of this paper is to report the cases of 7 patients (of a group of 93) who became mentally ill while taking Rauwolfia compounds, to emphasize the potential severity of the complication, and to evaluate possible factors involved in its genesis.

Initially all patients were treated with a crude root preparation of Rauwolfia, Raudixin. Subsequently Raudixin therapy was discontinued, and all patients were given the purified alkaloid, reserpine. These compounds were administered in ascending doses until satisfactory control of blood pressure was obtained or unpleasant reactions prevented additional increase of the drug. When control of blood pressure was not satisfactory, an additional hypotensive agent, either protoveratrine or pentolinium tartrate (Ansolysen), was administered in combination. Twenty-eight patients received Raudixin from 2 to 12 months (average 6 months) in doses varying from 100 to 700 mg. per day (average 336 mg.). Two (7%) patients became mentally ill; both received 400 mg. of Raudixin for periods of three and four months respectively. Sixty-five patients took reserpine from 2 to 10 months (average 5 months) in doses varying from 0.6 mg. to 4 mg. (average 1.5 mg.) per day. Five (7.7%) patients became mentally ill during the administration of 1.2 to 4 mg. (average 2.2 mg.) per day for periods varying from three to six months (average 4.4 months). Minor symptoms were observed in 86 patients similar to those described by previous investigators.[5]

In seven patients who developed serious mental difficulties, symptoms observed were insomnia (seven), fatigue and lassitude (six), inability to concentrate or work (five), anxiety and apprehension (five), crying episodes (four), drowsiness (four), feelings of futility and despondency (three), loss of previous interest (two), guilt feelings (two), self-accusation and self-depreciation (two), desire to withdraw from people (two), multiple physical complaints (two), suicidal thoughts (two), constipation (one), nervous uncomfortable feeling in stomach (one), loss of libido (one), and forgetfulness (one). All seven patients were hospitalized for periods of 10 to 30 days. The psychiatric diagnoses were anxiety depression, three patients; predominant depression with little anxiety, two patients; and anxiety state, two patients. Four patients improved initially on a simple regimen of rest, reassurance, encouragement, and drugs given to produce relaxation and sedation. Of these, two relapsed and received electric shock therapy with good results. The mental status in the remaining two patients has continued to improve after periods of four and seven months, even though one patient has developed malignant hypertension. Three patients failed to respond to psychotherapy in the form of ventilation and reassurance but improved promptly after electric shock therapy. Of these three patients, one has maintained improvement for 5 months; another patient with marked mental improvement for 5 months has retained her lifelong multiple organ system complaints and symptoms suggesting hyperventilation syndrome; and the remaining patient required additional electric shock therapy one year after initial treatment but continues to have feelings of anxiety and depression 15 months after the onset of his acute illness. The following case reports are included to illustrate briefly the psychiatric symptoms and clinical course of seven patients.

REPORT OF CASES

CASE 1.—A 49-year-old man was originally seen at Duke Hospital in May, 1953, with asymptomatic hypertension of six years' duration. He had enjoyed good health despite symptoms of anxiety for many years. Physical examination revealed blood pressure of 170 to 200/100 to 110 mm. Hg, grade 2 retinal changes, and moderate cardiac enlargement. After initial clinical evaluation, Raudixin therapy, 400 mg. a day, was begun. Blood pressure was controlled at normal levels until August, 1953, when medication was discontinued by the patient because of

5. Wilkins.[1] Doyle and others.[3]

the rapid development of lassitude, fatigability, insomnia, feelings of futility and hopelessness, a desire to withdraw from people, and suicidal thoughts. When he was seen at Duke Hospital two weeks after the onset of symptoms, a diagnosis was made of acute depressive reaction, possibly related to Raudixin. A history was obtained of previous short periods of mild depression. Electric shock therapy was administered at another hospital with good results, and he was not seen at Duke Hospital again until April, 1954. During the interim, periods of mild depression persisted, but therapy with Raudixin in a lower dosage of 100 mg. daily had been continued. In October, 1954, a more severe exacerbation of depression developed, and he again responded to electric shock therapy. When last heard from in January, 1955, he was feeling better, but periods of nervousness and depression continued to occur.

CASE 2.—A 42-year-old woman had had asymptomatic hypertension for 15 years and was hospitalized at Duke Hospital first in 1952 after a cerebral vascular accident with hemiplegia. Recovery from the hemiplegia was almost complete, and blood pressure was controlled satisfactorily by therapy with hexamethonium chloride and hydralazine. However, administration of these drugs was discontinued in September, 1953, after the development of arthritis as a complication of hydralazine therapy. Raudixin therapy, 400 mg. a day, was then started. Shortly afterwards, drowsiness, fatigue, lassitude, and loss of energy developed. In November, 1953, administration of Raudixin was reduced to 300 mg. a day with temporary improvement. In January, 1954, the development of nervousness; anxiety and agitation; insomnia; crying spells; burning pains in her chest; pressure in her head; and inability to concentrate, to make decisions, and to work resulted in the patient's hospitalization at Duke Hospital. A diagnosis of anxiety state was made. It is of interest that the patient had had a previous nervous breakdown at age 30 necessitating care in a sanitarium. Superficial psychotherapy combined with relaxation therapy resulted in marked improvement after two weeks. After returning home, therapy with reserpine was started by her personal physician and symptoms recurred. After several months she was hospitalized at another hospital where a diagnosis was made of personality trait disturbance of long standing verging into depression with anxiety. Reserpine therapy was discontinued, and electric shock therapy administered in December, 1954, resulted in less agitation. Reserpine therapy was reinstituted prior to discharge from the hospital but was discontinued by her personal physician after she returned home. Progressive improvement then occurred with restored abilities to perform household duties and to drive her car. When last seen at Duke Hospital in May, 1955, improvement in her condition was obvious. Previous anxiety symptoms had disappeared and 15 lb. (6.8 kg.) of weight had been gained. However, partial amnesia for details of her previous illness and mild impairment of concentration were evident.

CASE 3.—A 28-year-old woman was first seen at Duke Hospital in April, 1954, with a known history of hypertension of four years' duration. Physical examination revealed a blood pressure of 205/125 mm. Hg, grade 2 retinal changes, and moderate cardiac enlargement. Administration of reserpine, 1 mg. a day, was begun and increased to 2 mg. a day during the next two months. Drowsiness and fatigability of moderate degree were noted. In July, 1954, reserpine was reduced to 1 mg. a day because of excessive drowsiness, loss of energy, and inability to work efficiently. However, symptoms progressed and, in addition, loss of previous interests, feelings of futility and of hopelessness, mental sluggishness, inability to concentrate, crying spells, loss of appetite, and progressive insomnia developed. In spite of expressions of guilt, self-depreciation, and self-accusation, she retained aggressive impulses toward her husband and stepmother. Upon readmission to Duke Hospital in August, 1954, her mental status was that of depression with little anxiety. A history of previous periods of mild depression was then obtained. After an initial unsuccessful period of reassurance and supportive treatment, electric shock therapy was given with good results. Since November, 1954, previous lifelong multiple organ system complaints and symptoms suggesting periods of hyperventilation are still present, but depression has not recurred. Blood pressure control has been partially successful with cryptenamine (Unitensen).

CASE 4.—A 53-year-old man had a short period of depression at age 33 related to family responsibilities after death of parents. In 1952 a second episode of depression occurred during thiocyanate therapy for asymptomatic hypertension, but the drug was not thought to be involved in its genesis. When the patient was first examined at Duke Hospital in July, 1954, his blood pressure was 190/100 mm. Hg, there were grade 2 retinal changes, and there was slight cardiomegaly. Initial treatment consisted of administration of protoveratrine, 3 mg. daily, with insignificant lowering of blood pressure. In August, 1954, reserpine, 1.2 mg. a day, was given in combination with protoveratrine. Initial feelings of relaxation and well-being were subsequently followed by drowsiness and fatigue. These latter symptoms progressed along with the development of inability to work efficiently or to concentrate, loss of energy, insomnia, crying spells, loss of libido, constipation, and apprehension. When hospitalized at Duke Hospital in January, 1955, a diagnosis was made of recurrent depression and anxiety possibly related to reserpine therapy. Treatment consisted of reassurance, sedation for insomnia, and chlorpromazine (Thorazine) therapy to facilitate relaxation. After 10 days of treatment he was considerably improved but relapsed about two weeks after leaving the hospital. Electric shock therapy administered four weeks later produced striking improvement in his condition. Upon leaving Duke Hospital, his mental status was good and his blood pressure was normal without drug therapy.

CASE 5.—A 60-year-old man had been a successful businessman and happily married. There had been known hypertension for 20 years but no previous psychiatric disorder. Retinal vein occlusion resulted in his first admission to Duke Hospital in April, 1954. The blood pressure was 180/120 mm. Hg, and there was slight cardiac enlargement. His eye condition was treated with anticoagulant therapy; and Raudixin, 300 mg. daily, and protoveratrine, 1.5 mg. daily, were given for treatment of his hypertension. In May, 1954, reserpine therapy, 0.75 mg. daily, was started after discontinuing administration of Raudixin. In September, 1954, feelings of listlessness, despondency, and loss of energy developed. Crying spells, insomnia with early morning awakening, and suicidal tendency followed. Feelings of self-depreciation and self-accusation were absent. A nervous unhappy feeling in his stomach was a prominent complaint. Current environmental factors of possible importance were business difficulties and a serious illness of his wife. Administration of reserpine, which had not influenced blood pressure appreciably, was discontinued without improvement in his mental condition. In October, 1954, a gastrointestinal survey failed to demonstrate a cause for his abdominal complaints. In November, 1954, after failure to respond to reassurance and supportive therapy, electric shock therapy was followed by striking improvement. Subsequent outpatient evaluation on April 15, 1955, revealed continued improvement even though his wife had recently died. He no longer seemed agitated and spoke of his past illness with considerable insight.

CASE 6.—A 42-year-old woman was first seen at Duke Hospital in April, 1954, with a history of periods of nervousness and anxiety of many years' duration and known hypertension for one year. Physical examination revealed a blood pressure of 220/120 mm. Hg, grade 2 retinal changes, and slight cardiac enlargement. After clinical evaluation, initial treatment consisted of administration of reserpine and protoveratrine, 2 mg. a day respectively. Moderate fatigue, lack of energy, and drowsiness developed after several weeks of therapy. In July, 1954, reserpine therapy was increased to doses of 4 mg. a day because of unsatisfactory control of blood pressure. During the next few weeks, symptoms of fatigue and drowsiness became worse, and progressive insomnia, inability to concentrate or to work, crying spells, and guilt feelings developed. During hospitalization at Duke Hospital in August, 1954, her moods fluctuated between periods of apprehension and depression and periods of relative relaxation. During subsequent psychiatric examination, feelings were expressed of unworthiness toward God and a fear that "God would cause her to become insane before she had a chance to repent." Other complaints were an empty feeling in her head and sensations of sweating and coldness over her body. Treatment consisting of reassurance, occupational therapy, and full ventilation of her anxieties resulted in progressive improvement that has been maintained. In April, 1955, hospitalization at

Duke Hospital was necessary again because of early malignant hypertension, but there has been no recurrence of her mental symptoms.

Case 7.—A 44-year-old man had been energetic, hard-working, well adjusted, and had never suffered from mood swings. He was first seen at Duke Hospital in 1952 with a four year history of progressive hypertension. From this time until May, 1954, his blood pressure was satisfactorily controlled with combined hexamethonium and hydralazine therapy. In July, 1954, after a control period without drug therapy, his blood pressure was 190 to 220/100 to 110 mm. Hg, there were grade 2 retinal changes, and there was moderate cardiomegaly. Reserpine therapy with doses of 2.4 mg. a day was started and for an initial period of two months he felt happier and less irritable. In November, 1954, nasal stuffiness and fatigability developed, and his favorite sport of golf was no longer enjoyed. Gradually, loss of interest, inability to concentrate, loss of memory for recent events, and inefficiency for work developed to the point where he became apprehensive in regard to the future of his employment. While normally he could dictate letters easily and make decisions quickly, he now would postpone any decisions as long as possible and needed extra time and effort to execute his actions. There was lack of energy at home and withdrawal from social activities because of inability to enter into conversation. Insomnia with early awakening developed, but his appetite and libido remained unchanged. Suicidal thoughts and feelings of self-accusation and condemnation were denied. Because of his mental symptoms he was hospitalized at Duke Hospital in January, 1955. It was the opinion of the psychiatrist that reserpine therapy appeared to have precipitated a psychopharmacological reaction primarily of anxiety and agitation in a man who in his job as purchasing agent depended on his memory and mental faculties for his livelihood and who had begun to feel uneasy and insecure about his economic future. Treatment consisted of reassurance, chlorpromazine therapy to help promote relaxation, and sedatives for insomnia. After two weeks, he was sufficiently improved to leave the hospital. His mental status has continued to improve, and, when last heard from in April, 1955, he was getting along well except for mild insomnia.

COMMENT

The majority of patients receiving Rauwolfia compounds undergo some alteration in mood while taking this drug. Some patients note feelings of relaxation, tranquility, and a sense of well-being with abolition of anxiety and agitation. Other patients fare less well and complain of lethargy, drowsiness, fatigue, and loss of initiative and previous interests. Freis reported recently five cases of severe depression occurring in patients on Rauwolfia therapy for hypertension.[4a] Locket noted development of depression in 5 of 39 patients, with attempted suicide in one patient, during Rauwolfia therapy for hypertensive vascular disease.[6] Genest and associates found nervous depression and fear occurring as a complication in 4 of 76 patients during Rauwolfia therapy.[7] Doyle and Smirk observed depression occurring in 11 out of 28 patients who received reserpine in large amounts. However, no comment was made regarding the severity of depression.[8] Several other authors mention depression as a complication occurring during reserpine therapy but fail to emphasize its frequency or severity.[9] In the present report concerning seven patients who became mentally ill while receiving Rauwolfia, anxiety and agitation were prominent by contrast to depression with little anxiety reported by Freis.[4a] Suicidal tendencies were present in two patients.

Administration of Rauwolfia in large doses appears to be important in the genesis of depression and anxiety that may develop.[10] For the five patients who developed these symptoms while receiving reserpine, the dosage ranged from 1.2 mg. to 4 mg. a day, which is in excess of the currently recommended dose of less than 1 mg. of reserpine a day.[11] In addition, two patients developed mental illness while receiving 400 mg. of Raudixin a day. While Freis did not observe depression to occur in patients receiving Rauwolfia compounds other than reserpine, additional preparations were used infrequently.[4a] In accord with previous observations,[4a] prolonged administration of Rauwolfia for periods varying from three to six months preceded the onset of mental illness. In general, the illness developed gradually and appeared primarily in patients for whom the drug had produced excessive unpleasant symptoms. The illness progressed in three patients despite a reduction in drug dosage. In one patient, the illness developed acutely without significant preliminary reactions. The slow convalescence after discontinuance of Rauwolfia therapy may be related to slow elimination of the drug. While three of seven patients received protoveratrine simultaneously with Rauwolfia, mental illness has not been recognized as a complication of protoveratrine therapy. Disturbing environmental factors active at the onset of mental difficulty were of possible significance in only one of seven patients. Doyle and associates have observed that administration of Rauwolfia compounds frequently aggravates preexisting depressive states.[8] While none of our seven patients were mentally ill at the onset of Rauwolfia therapy, it is of particular interest that five patients gave a history of previous psychiatric illness. It is thus suggested that therapy with Rauwolfia extracts may trigger or precipitate a mental illness in somewhat unstable patients already predisposed. Although the exact pharmacological action of Rauwolfia is not completely understood, current evidence indicates that its hypotensive action is upon the central nervous system, most likely the hypothalamus.[12] Alterations of mood observed in patients during Rauwolfia therapy may also result from the drug's action on the hypothalamus, but the genesis of these alterations is not clear.[12]

Kline has observed beneficial effects in patients with psychoneurosis while receiving Rauwolfia in that this drug tends to relieve abnormal inhibition and excessive preoccupation with the opinion of other people. Obsessive and compulsive behavior was also diminished.[13] Among our patients, there was a willingness to talk about preexisting psychiatric disturbances and in some almost a desire to confess previous indiscretions.

If the development of agitation and depression are to be avoided during prolonged Rauwolfia therapy, certain precautions may be helpful in reducing this complication. Although the exact optimum dosage of reserpine

may vary slightly among different patients, most investigators agree that the daily dosage should preferably not exceed 1 mg. a day.[11] During prolonged therapy, the drug should be reduced gradually to the minimum amount that will produce satisfactory control of blood pressure. Close observation is mandatory for patients whose histories indicate previous psychiatric disorder. When complaints of excessive fatigue, loss of interest and initiative, inability to concentrate or work efficiently, insomnia, "feeling blue," or excessive nervousness appear, Rauwolfia dosage should be reduced promptly or discontinued temporarily. Further administration of Rauwolfia under these circumstances may result in a state of anxiety or depression.

SUMMARY

A severe mental illness developed in 7 (7.5%) of 93 patients receiving Rauwolfia for periods of 2 to 12 months. Two (7%) of 28 patients developed this illness while receiving a crude root preparation, Raudixin, and 5 (7.7%) of 65 patients while taking the purified alkaloid, reserpine. The mood disturbance was primarily depression in two patients, depression with anxiety in three patients, and anxiety state in two patients. Suicidal tendencies were present in two patients. A history of previous psychiatric illness was obtained from five patients. All patients received reserpine in dosage relatively large as compared to that currently recommended. Two of the seven patients responded to reassurance and supportive therapy. Five patients required electric shock therapy. The response was good for three patients and fair for two patients. The potential severity of this complication arising during Rauwolfia therapy is fully emphasized. Caution in Rauwolfia administration is recommended, with particular reference to total daily dosage and to previous psychiatric history.

PSYCHOSIS APPARENTLY PRODUCED BY RESERPINE

Henry A. Schroeder, M.D.
and
H. Mitchell Perry Jr., M.D., St. Louis

The use of reserpine has become widespread, both for its tranquilizing effect in hypertension [1] and its curiously unexplained action in schizophrenic reactions and other psychotic and psychoneurotic states.[2] The fact that a yohimbine-like drug will act upon specific functions of the brain, probably on the hypothalamus or its connections, has opened the way to investigations on the chemical disorders of cerebral metabolism leading to functional disturbances. Reserpine and its chemical analogues are said to be safe and free from serious side-effects. Because psychoses developed in five individuals taking this drug, with slow recovery after withdrawal, and because nervousness, insomnia, and agitation have appeared in others, we considered it advisable to call attention to such reactions.

REPORT OF CASES

Case 1.—A 60-year-old bookkeeper had exhibited asymptomatic hypertension for at least two years. There had been no episodes of overt psychosis or neurosis during his lifetime. His blood pressure was 212 mm. Hg systolic and 110 mm. diastolic; grade 2 (Keith-Wagener) ocular fundi were seen; and his electrocardiogram showed a left ventricular strain pattern. He was given 1.0 mg. of reserpine a day early in March, 1954. Seven weeks later he complained of excessive drowsiness; his blood pressure was 210 mm. Hg systolic and 100 mm. diastolic. The dose was reduced to 0.5 mg. Eleven weeks after beginning therapy he telephoned, saying that he was nervous, forgetful, and wept easily. The dose was reduced to 0.25 mg. a day. He did not return to us, but by the 17th week he exhibited severe paranoid depression with suicidal tendencies and spent one month in another hospital under observation by a psychiatrist. Recovery was slow but complete when administration of the drug was omitted, and no further psychosis developed even during emotional shock following the sudden death of his wife.

Case 2.—A 59-year-old woman had suffered from severe arterial hypertension for 19 years, with headaches and dizziness as her principal symptoms. Her blood pressure was 252 mm. Hg systolic and 118 mm. diastolic; her heart was moderately enlarged in x-ray photographs and by electrocardiogram and her renal function good. She was treated in November, 1953, with graduated oral doses of hexamethonium chloride and hydralazine hydrochloride, with an average blood pressure of 170/90 mm. Hg achieved at home. In addition, the whole root of Rauwolfia serpentina was given, 250 mg. per day, and was discontinued after four months. Reserpine therapy, 1.0 mg. per day, was begun in July, 1954. In early September she became depressed, agitated, frightened, and paranoid, with considerable mental dulness. She was afraid of losing her mind. Readmitted to the hospital in October, she exhibited severe depression with marked paranoia, which at one time was overt enough for her to be confined to the violent ward for a night. Suicidal threats became obvious, and a psychiatrist considered her a definite risk. Reserpine therapy was discontinued and depression gradually improved, but for a month wide swings in mood were noticed and constant attendance to avoid suicide was required. Six weeks after therapy was stopped, she was clear mentally and has remained so. No prior psychotic episodes were known.

Case 3.—A 47-year-old woman had exhibited moderate arterial hypertension for three years and had suffered one cerebral hemorrhage, the sequelae of which were apparently minimal. She had never experienced psychotic episodes but was somewhat depressed during her menstrual periods all her adult life. In December, 1953, her blood pressure was 180 mm. Hg systolic and 108 mm. diastolic, without other signs of damage to her cardiovascular system. Cerebral angiogram revealed no aneurysm. She was given the whole root of Rauwolfia serpentina, 200 mg. per day, and hydralazine hydrochloride, 100 mg. per day. During the subsequent seven months, repeated episodes

of depression appeared with hysterical behavior and outspoken threats of suicide; these became marked enough to cause her admission to the psychiatric service, where she was given seven electroshock treatments. She was severely depressed but cleared slowly and was discharged after six weeks, taking reserpine, 1.0 mg. per day, for moderately hypertensive levels of blood pressure. Readmission was required, however, six weeks later for recurrence of depression, agitation, nervousness, insomnia, and suicidal threats. She was given a total of 14 electroshock treatments and discharged seven weeks later partially improved but now receiving reserpine, 4.0 mg. per day. She continued to be depressed, agitated, and nervous for the following two months, when reserpine therapy was reduced to 1.0 mg. per day and then discontinued. During the subsequent six week period she recovered completely.

CASE 4.—A 45-year-old Negro woman had suffered from the malignant stage of hypertension, congestive heart failure, and impaired renal function with mild azotemia in April, 1954. She was treated with graduated doses of ganglionic blocking agents, hydralazine hydrochloride, 750 mg. per day, and the whole root of Rauwolfia serpentina, 300 mg. per day, with excellent results. In August, however, she developed "hydralazine disease"[3] with hepatitis, was readmitted to hospital, and recovered after a stormy course lasting three months. During the expected return of hypertension when hydralazine therapy was discontinued, large doses of ganglionic blocking agents and reserpine, 1.0 mg. a day, were given; after one week, 2.0 mg. of reserpine was administered daily intramuscularly for two days. She became uncooperative, incontinent, disoriented, apprehensive, and depressed; occasionally she was lethargic and visual hallucinations appeared. These symptoms worsened for three days, appearing and disappearing, but she recovered completely seven days after reserpine therapy was discontinued. Insofar as is known, she had not exhibited psychotic behavior previously.

CASE 5.—A 51-year-old man had exhibited moderate arterial hypertension for eight years in December, 1954. Partial gastrectomy had been performed in 1946 for peptic ulcer. He was a tense individual with excessive drive but had never suffered from a psychotic episode. Aside from persistent hypertension of 170 to 240 mm. Hg systolic and 100 to 130 mm. diastolic pressure, few abnormalities were discovered in hospital. He was given reserpine, 1.0 mg. per day, and hydralazine hydrochloride, 400 mg. per day, in divided doses. Mild depression was noticed in January, 1955, which continued. In early May he began to become agitated, more depressed, and expressed a fear of dying or becoming insane. He was readmitted to the psychiatric service June 8, when reserpine and all other therapy was discontinued. He was given chlorpromazine, 100 mg. a day, for three weeks without improvement, then nine electroshock treatments, and was discharged as recovered nine weeks after admission.

COMMENT

In three of these five individuals, prodromal symptoms consisted of increased nervousness, insomnia, agitation, and depression. Continuation of the therapy with the drug then resulted in the sporadic but increasingly recurring bouts of paranoia with suicidal tendencies, followed by lucid intervals with clear insight. Recovery was slow and was achieved in from one to two months. In the fourth patient, acute psychosis appeared after parenteral administration of reserpine, with a week required for recovery; the patient was suffering from "hydralazine disease" and may have been more susceptible to a disorder of cerebral function, although psychosis has not been observed in delayed toxic reactions to this drug. We have come to recognize that administration of reserpine, usually a sedative agent, may cause excitement in some individuals; when a patient taking this agent for a month or more complains of increased nervousness, we reduce the dosage or omit the administration of the drug. Reactions of this nature have been observed a number of times in hypertensive patients. One can only speculate on the cause of the reverse reaction of this sedative drug. The doses used were not abnormally high, not exceeding standard sizes dispensed in pharmacies. Freis[4] reported five cases of patients with mental depression, apparently brought on by reserpine, occurring two to four months after institution of therapy with 1.0 to 2.0 mg. doses daily, four patients recovering rapidly after withdrawal. In two, suicidal tendencies were seen, but none required hospitalization. One suicide was recently reported in a psychotic individual; mental confusion, grand mal convulsive seizures, and Parkinsonism also occurred, apparently induced by the drug.[2c]

Other reactions to this drug have been observed. Although most of them have been of a mild nature, recurrence of peptic ulcer with bleeding has occurred in three patients, one requiring subtotal gastrectomy for perforation; ulcer has developed in one. Severe mucous colitis with small ulcerations has occurred in one. These five formerly hypertensive patients were normotensive after intensive therapy for two to three years. While it is not certain that gastrointestinal conditions are influenced by administration of reserpine, the drug could conceivably act as an initiating factor in view of the relative parasympathetic stimulation that is produced. Although in most individuals reserpine therapy appears to be relatively innocuous, especially in small doses, adverse reactions on mental function and on peripheral autonomic areas must be considered in any individual receiving this drug.

SUMMARY

Psychotic behavior with agitated depression has occurred in five patients receiving reserpine, with complete recovery when the drug was discontinued. Such behavior had not been known in these patients prior to taking this drug.

Cause of Obesity.—Obesity takes many forms and is the end result of various interacting factors, extrinsic and intrinsic. The extrinsic causes of obesity include excessive caloric intake, and perhaps nutritional deficiencies as well; relative inactivity; toxic effects, and possibly stress situations. The extrinsic factors may bring certain of the intrinsic causes of obesity into operation. The intrinsic causes include the constitutional, the diencephalohypothalamic, the endocrine metabolic, and the enzymatic. All of these may be interrelated and interactive. Anywhere along the pathways of the numerous intricate reactions of carbohydrate-fat metabolism, of fat mobilization, and of fat deposition, a disturbance might occur which conceivably could lead to obesity. There is now experimental evidence that in one known form of obesity the pancreas is involved. Although perhaps less conclusive, results indicate also that other endocrine glands, the adipose tissue, and enzyme systems play at least a part-role. That hyperphagia or inability to recognize satiety may lead to obesity is demonstrated by experiments with hypothalamic induced lesions or stimulation. Again, metabolic factors may be concurrently involved.—M. B. Fertman, M.D., Newer Concepts of Experimental Obesity, *A. M. A. Archives of Internal Medicine,* June, 1955.

HYPERTENSION TREATED WITH RAUWOLFIA SERPENTINA (WHOLE ROOT) AND WITH RESERPINE

CONTROLLED STUDY DISCLOSING OCCASIONAL SEVERE DEPRESSION

Richard W. P. Achor, M.D., Norbert O. Hanson, M.D.
and
Ray W. Gifford Jr., M.D., Rochester, Minn.

Beginning with the provocative report by Vakil[1] in 1949, and especially since Wilkins and his associates[2] introduced the drugs into the United States, preparations of Rauwolfia serpentina have been used with increasing frequency in the treatment of essential hypertension. In 1952 the highly purified alkaloid, reserpine, was isolated from Rauwolfia serpentina,[3] and this has been thought to be its chief active principle.[4] If this is true and if both preparations are equally effective, then it would seem preferable to use a single highly potent alkaloid rather than the mixture of various substances contained in the crude root. However, there has been some doubt as to whether reserpine is as efficacious as the whole root in the treatment of hypertension. We are here reporting the observations made in a controlled comparative study in which both the crude drug and reserpine were used in the treatment of essential hypertension.

PROCEDURE

Selection of Patients.—Most workers have suggested that, when used alone, Rauwolfia is most effective for the treatment of hypertension of mild to moderate severity; hence we endeavor to select such patients. Ambulatory patients from the local territory were accepted if their average blood pressure exceeded 165 mm. Hg systolic and 90 mm. diastolic during an observation period of two or more months prior to the study. In all patients there was ample previous history or records to verify the presence of chronic and sustained hypertension. All patients underwent complete physical examinations and sufficient additional studies to eliminate cases of secondary hypertension and to furnish data needed in assessing the severity of the hypertension.

Composition of Sample.—In all, 58 white adult patients were selected. Fifteen were male and 43 female, giving a ratio of 3 women to one man. Their ages ranged from 35 to 79 years, with an average age of 57 years. The discovery of hypertension could be dated with reasonable accuracy in 50 patients from previous medical records, and in these the average duration of hypertension since discovery was 11½ years. The average blood pressure for all patients prior to the study was 193 mm. Hg systolic and 110 mm. diastolic. The numbers of patients in the various ranges of blood pressure elevation are shown in table 1. In about two-thirds of the patients phenobarbital was administered during this period of observation.

Examination of the ocular fundi revealed that 54 persons had hypertensive changes that were graded group 1 or 2 by the Keith-Wagener-Barker classification. Four patients had retinal findings that were graded group 3, and none with group 4, or malignant hypertensive retinopathy, were included. The concentration of blood urea was within normal limits in all but eight patients; in seven of these persons the concentration was between 40 and 50 mg. per 100 cc., and in one it was 64 mg. per 100 cc. Five patients had residual evidence of previous cerebral infarction but were entirely ambulatory. A number of patients had some cardiac abnormality, as seen in the following breakdown: 12 persons showed definite enlargement of the cardiac silhouette on routine roentgenograms of the thorax; 21 had changes in their electrocardiograms suggestive of left ventricular hypertrophy; 11 gave a history compatible with insufficiency of the coronary arteries, and 3 of these were known to have sustained a previous myocardial infarction; and 4 patients required active treatment for congestive heart failure at the onset of the study.

Table 1.—*Average Values for Blood Pressure Before Study Periods*

Systolic Pressure	Patients	%	Diastolic Pressure	Patients	%
160-179	17	29	90-104	17	29
180-199	22	38	105-119	28	48
200-219	13	22	120-134	12	21
220-250	6	11	135+	1	2
Total	58	100	Total	58	100

Methods.—The study was conducted as a "double blind"; that is, neither the physicians nor the patients knew when an active drug was given nor just which drug was being administered. All the tablets—active drugs and placebo—appeared identical, and all were administered in the same manner in four doses a day throughout. The patients came in weekly at their own convenience, and after a period of rest the blood pressure was taken several times by a physician while the patient was in the sitting position. The two lowest readings together with the pulse rate were recorded, along with relevant notes as to the patient's progress and as to side-effects. Any

additional examination that was needed could be carried out at these visits.

After six months had elapsed, the patients were again examined and the necessary studies were made. At this time the schedule of administration of medicine and placebo was revealed so that the data could be compiled. In brief, the patients were given initially and alternately either the whole-root preparation of Rauwolfia serpentina in the amount of 400 mg. per day or reserpine in the amount of 0.4 mg. per day. This dosage ratio of 1 for reserpine to 1,000 for the crude drug has been tentatively accepted as being equivalent pharmacologically.[5] These medicines were administered for two months, then the placebo was given for the next two months, and finally the whole-root preparation or reserpine, whichever had not been administered originally, was given for the last two months.

RESULTS

In general, the patients were most cooperative and faithful in their visits. Of 58 patients who started, 53 completed the entire six month period of study. The following reasons are given for failure of five to complete the study. 1. Two patients sustained cerebrovascular accidents during the study and were hospitalized. 2. Another patient experienced such distressing abdominal cramps, bloating, and diarrhea that, despite a great decrease in the dosage, she had to be excluded from the study. 3. In the two remaining patients such severe emotional depression developed that it was imperative that medication be discontinued. Hence, the data to be presented are based on the 53 patients studied for the entire six months.

Effect on Blood Pressure.—The average blood pressure for all patients was 166/96 mm. Hg while they were taking the whole-root preparation and 165/97 while they were taking reserpine (table 2). Compared with pretreatment values, these represent decreases of 27 and 28 mm. Hg, respectively, in systolic pressure and 14 and 13 mm. Hg, respectively, in diastolic pressure. These same data are presented in more detail in table 3 to show the ranges of reduction in blood pressure. It was observed that the crude root appeared to produce more profound falls in diastolic blood pressure than did reserpine. This was also indicated by the observation that in five patients the crude drug produced a fall in diastolic blood pressure that was 10 mm. Hg or more greater than that obtained with reserpine, while the latter drug attained this result in only two individuals. There was a reduction in average diastolic blood pressure by 15 mm. Hg or more from pretreatment values in 25 persons (47%) with use of the whole root and in 21 patients (40%) with use of reserpine. In the main, however, there certainly was no appreciable difference in the ability of the two drugs to lower blood pressure. Their use did result in reduction of blood pressure from pretreatment levels by 30 mm. Hg or more systolic or by 15 mm. Hg or more diastolic in 40% of the patients treated.

TABLE 2.—*Average Values for Blood Pressure and Pulse Rate During Study Periods*

			Treatment Period		
		Before Study	Whole Root	Reserpine	Placebo
Systolic pressure		193	166	165	170
Diastolic pressure		110	96	97	102
Pulse rate		81	67	69	77
Values for the First and Second Month of Each Period					
Systolic pressure	1st month		167	167	166
	2nd month		165	163	174
Diastolic pressure	1st month		97	98	100
	2nd month		95	96	104
Pulse rate	1st month		67	69	75
	2nd month		67	69	79

TABLE 3.—*Reduction of Blood Pressure During Treatment*

		Whole Root		Reserpine	
	Reduction	Patients	%	Patients	%
Systolic pressure	None or increased	4	8	1	2
	1-14	9	17	9	17
	15-29	18	34	22	41
	30-44	17	32	18	34
	45-60	5	9	3	6
	Total	53	100	53	100
Diastolic pressure	None or increased	2	4	1	2
	1-9	12	23	11	21
	10-19	26	49	36	68
	20-29	13	24	5	9
	Total	53	100	53	100

During the intermediate two months, when the placebo was administered, the average pressure rose to 170/102 mm. Hg. This represents considerable decrease of average blood pressure from that of the pretreatment period and seemed best accounted for by two main factors. First, the effect exerted on blood pressure by Rauwolfia, either as whole root or as reserpine, lasted two to six weeks after its use had been discontinued. In a similar manner it was frequently observed that a similar period of two to six weeks was needed to obtain the maximal hypotensive effect after the beginning of medication. To test this observation, the average blood pressures for the first and second months of each period of drug administration and for the period of placebo administration were determined separately, since this would allow for a month of treatment with each medicine before its effect was assessed and would also permit a month for the drug to dissipate before the effect of the placebo was evaluated. The values for the second month of each period indicated an increased spread between the average blood pressure during treatment with an active drug and the average observed during the period of placebo administration (table 2). Thus, treatment of hypertension with Rauwolfia (crude root or reserpine) should not be abandoned until a trial period of at least two months has elapsed. The second factor in the reduction of blood pressure during the period of placebo administration, as compared with prestudy levels of blood pressure, was undoubtedly a psychogenic one. Certainly the patients became much less apprehensive about having their blood pressure taken as the study progressed. Then, too, the psychological effect of administering even a placebo is well known to result in some lowering of blood pressure.

Effect on Pulse.—The ability of the two drugs to slow the pulse rate was a most pronounced and readily apparent one that was demonstrated in nearly every patient, regardless of the effect on blood pressure (table 2). A decrease in pulse rate usually preceded any pronounced decrease in blood pressure, and the return of the pulse rate to pretreatment levels was more prompt after the administration of Rauwolfia had been discontinued than was the corresponding return of the blood pressure. It was through these observations that the period of placebo administration could be identified in nearly every patient without knowledge of the schedule of drug administration. Kline [6] and Harris [7] have made similar observations in this regard. In some patients the pulse decreased to rates between 45 and 55 per minute, and, although many patients remarked about the slow pulse rate, only one felt that it was disagreeable.

[5] Green, H. D.: Pharmacology of Antihypertensive Drugs, Am. J. Med. 17: 70-83 (July) 1954.

Beneficial Effects.—At the conclusion of the study nearly every patient expressed the wish to continue the medication even at his expense and despite the rather frequent occurrence of annoying side-effects. Subjectively, the principal benefit described was a feeling of well-being, freedom from much of the former tenseness, and the ability to relax. It was our impression that many patients reacted less strongly to environmental stimuli while taking the active drugs than they had prior to treatment.

Perhaps even more interesting was the improvement noted in the hypertensive sequelae of some patients. Reexamination of the ocular fundi at the conclusion of the study revealed distinct improvement in the retinal findings of 12 persons, with definite worsening described in two additional patients. Upon completion of the six month period, the value for blood urea was normal in four of the patients with previously elevated values. However, the values for two individuals were now mildly elevated when they had been normal originally. The value for one other patient increased from 64 mg. to 76 mg. per 100 cc. during the study period. Twelve people complained of headache or dizziness prior to the study period, and six were relieved of these complaints during treatment.

Of the 11 persons with pain from insufficiency of the coronary arteries, 4 seemed distinctly benefited in this regard at the time of reevaluation. Seven of the 21 patients with electrocardiographic evidence of left ventricular hypertrophy had more normal tracings at the end of the study period. The remaining 14 were essentially unchanged. Three of the 12 patients with an enlarged cardiac silhouette on roentgenograms of the thorax at the beginning of the study had normal-sized heart shadows upon completion of the six month period. Two patients with congestive cardiac failure improved to such extent during treatment that the use of digitalis was discontinued and no additional medicaments were required.

Prior to beginning the study we endeavored to predict which patients would respond favorably to the use of Rauwolfia preparations. We had believed that younger persons, in whom there were increased emotional factors and in whom serious complicating hypertensive sequelae had not yet developed, would show the best responses. It was instructively disappointing to find that our efforts to predict the good results were unsuccessful in the majority of instances. Only by an adequate trial of treatment can one determine which patients will obtain satisfactory control of their hypertension.

Side-Effects.—The evaluation of side-effects arising from the use of any drug is difficult to do in an objective manner. In this study we did not attribute any complaint to use of an active drug if it was also experienced to a similar degree during administration of the placebo. In an effort to avoid suggestibility, no patient was informed as to the possible side-effects that might arise, and in questioning the patients as to their progress we encourage them to volunteer their own observations instead of asking them specific questions relative to the effects of drug therapy. Data on the side-effects encountered are given in table 4. Of the total complaints, 119 occurred during the use of the whole-root preparation, 111 were attributed to the use of reserpine, and only 31 were noted during the period in which the placebo was administered.

Nasal stuffiness or congestion was the commonest undesirable effect and was most bothersome when the patient was recumbent. The crude root not only caused this complaint more often than did reserpine but also produced more severe symptoms. Our efforts to relieve this distress by the use of vasoconstrictive nasal sprays and inhalers and with antihistaminic drugs was unsatisfactory in most instances. This observation is in agreement with that made by Green,[5] although Freis and Ari [8] said that antihistamines were of distinct value in avoiding nasal stuffiness and Kline obtained good results with naphazoline (Privine) hydrochloride. At no time did use of the drugs have to be discontinued, and most patients were able to tolerate the stuffiness without excessive difficulty. A sedative or calming effect occurred equally with use of the two drugs, and in the doses given they showed no difference in degree of sedation produced. For the most part, this effect was beneficial and desirable.

An increased appetite was noted by nearly every patient at some time during the study, but it was impractical to compare the three periods of drug administration in regard to this effect. The evaluation of this effect would be made especially difficult because of the fact that the patients frequently were obese and were constantly encouraged to reduce weight. In spite of this advice, how-

ever, 75% of the patients gained weight during the study period, and this gain averaged 6 lb. (2.7 kg.) per person. Seventeen per cent of the patients lost an average of 6 lb. per person, and 8% remained unchanged. For those patients who gained weight, the average lowering of diastolic blood pressure for the six month study period was 11.7 mm. Hg, compared with 12.8 mm. for the patients who lost weight. Thus, the gain or loss in weight by the patients did not appear to cause any appreciable effect on their blood pressure. Nearly half (42%) of the patients felt that they had a definitely increased tendency to dream or to have nightmares while they were undergoing active medication. Reserpine seemed to be a slightly greater offender in producing this effect. For the most part, the dreaming was unpleasant and bothersome. The dreams often related to the individual's early life or were concerned with the sustaining of bodily injury and the infliction of harm on others. Occasionally, erotic dreams were experienced. Increase in looseness of the bowel movements with increased abdominal cramping was present in 28% of the patients while they were taking either drug. This effect tended to be more prominent when reserpine was being taken, but it was excessive in only one patient and caused her to discontinue the study entirely.

Emotional upsets developed in 10 of the 58 patients during the course of study, and these concerned us a great deal. The mildest form of upset consisted of increased tenseness, restlessness, insomnia, and a feeling of being very uncomfortable. This could progress to an outright episode of depression that seemed indistinguishable from those observed in psychiatric patients without hypertension. Three patients experienced a truly major depression; one of these required electroshock therapy, another was under psychiatric care for many months, and the third left town abruptly and we were not able to contact her again for three months. Then we found that she had been hospitalized and was under psychiatric care. Two of these patients were eliminated from the study, but the third completed the six month period and was continued on treatment with reserpine. Subsequently, she again experienced depressive symptoms and administration of the drug was promptly stopped. On this occasion she did not become as severely depressed as previously, and she recovered without the use of electroshock therapy. Three additional patients were considered to be moderately depressed, and four others experienced mild but definite depressive episodes. Since completion of the study, two more patients have experienced moderately severe depressive reactions that required cessation of Rauwolfia therapy. There did not appear to be any significant difference between the crude root and reserpine in promoting these depressive episodes.

In a small number of patients there were complaints that could not be adequately accounted for but that seemed to be definitely related to use of the drugs and were similar to those observed by others. These were muscle aching and cramps, headaches, odd chilly sensations and sensitiveness to cold, episodes of unexplained shortness of breath,[9] dizziness, and urinary urgency and frequency with negative results on genitourinary investigation.[10]

COMMENT

In this study we could not find any appreciable difference between the effects of the crude-root preparation of Rauwolfia serpentina and those of its purified alkaloid, reserpine. This similarity of results pertained not only to effects on blood pressure and pulse but also to the production of side-effects. If any difference existed, it was the tendency for the crude root to produce side-effects in greater frequency and severity. It must be pointed out that the daily dose of 0.4 mg. of reserpine is rather small, and we cannot say what might have resulted from use of larger doses. Our results agree with those of Wilkins and co-workers [4a] and with those of Green [5] in support of the belief that reserpine is the chief active principle of Rauwolfia serpentina.

It has been shown by many investigators that in some cases of essential hypertension preparations of Rauwolfia serpentina can be used with good results as the sole antihypertensive drug. Most clinicians are agreed that these good responses occur more often in cases of mild to moderate hypertension. In our study, 40% of the patients obtained a satisfactory reduction in blood pressure. This is more than the one-fourth of patients adequately controlled with moderate doses reported by Doyle and co-workers [9b] but less than the 50% observed by Livesay and co-workers.[11] Longer observation is needed, of course, to ascertain ultimate results, but a year after beginning this study these results still seem to be valid. We have observed, as have others, that frequently Rauwolfia therapy for two to six weeks is needed to obtain maximal hypotensive effect and that this effect often persists for an equally long time after use of the drugs has been discontinued. This prolonged effect of Rauwolfia suggests that administration of the drug more often than once daily is probably unnecessary, though we could not test this from our present data. In addition, we could find no adequate means of predicting the patients whose hypertension would respond well to treatment.

The most disturbing and unexpected observation to come out of this study is the frequency with which mental depressive states developed. This effect has been noted by others,[12] but the severity to which the symptoms can progress has not been sufficiently stressed. Dustan and co-workers [13] and Freis [14] have called attention to this, but in the cases that they reported several antihypertensive drugs were used. In our study Rauwolfia was the only antihypertensive agent used, and in most cases it was the only drug administered. We do not believe that the development of depressive reactions in our study was merely coincidental.

In our experience with Rauwolfia preparations in the treatment of approximately 70 other hypertensive patients who have been followed since January, 1954, we have encountered 15 patients with depressed states; of these, one patient committed suicide, another attempted suicide, 2 had very severe manifestations that required electroshock treatment, 4 had moderately severe manifestations and required prolonged psychiatric management, and the remaining 7 had milder manifestations but had to be taken off treatment with Rauwolfia. These reactions have usually occurred after the drug has been administered for at least two months, and they have been observed after use of various preparations of Rauwolfia, namely whole root, alseroxylon fraction, and reserpine.

Because of the seriousness of this problem, nearly all patients with a depressive reaction have had psychiatric evaluation, and this problem is the subject of continuing investigation. We have been advised that all such patients had ample psychological background to render them susceptible to development of a depression. However this may be, it is our present belief that Rauwolfia serpentina increases the vulnerability of these susceptible persons to factors in their environment that may promote a depressive response. We believe that the seriousness and frequency of these reactions constitute a major contraindication to the indiscriminate and unsupervised use of Rauwolfia preparations in persons with essential hypertension. Since these drugs are quite useful in treating hypertension and since other side-effects attending their use are not serious, it would be most worthwhile if some means could be found to recognize, prior to beginning treatment, those patients who might become depressed. It is to be hoped that further study of this problem will shed light on how to avoid such distressing and disabling depressive reactions.

SUMMARY AND CONCLUSIONS

In a controlled study of 58 patients with essential hypertension, the effects of treatment with a whole-root preparation of Rauwolfia serpentina compared with the effects of treatment with the purified alkaloid, reserpine, revealed that, with the dosage used, the effects produced by the whole-root preparation did not appear to be significantly different from those produced by reserpine. Treatment with these preparations produced a satisfactory reduction of blood pressure in 40% of the patients. The use of Rauwolfia preparations is associated with a number of disagreeable side-effects, most of which are not serious. However, the occurrence of severe depressive reactions constitutes a serious objection to the indiscriminate and unattended use of these drugs.

OPERATIVE RISK IN PATIENTS WITH CORONARY HEART DISEASE

Benjamin Etsten, M.D.
and
Samuel Proger, M.D., Boston

There is general acknowledgment that patients with hypertensive heart disease, valvular heart disease, or noncyanotic congenital heart disease who are not in heart failure present little, if any, greater operative risk than patients without such abnormalities.[1] There is a feeling, however, that the presence of coronary heart disease greatly increases the surgical risk, since published studies show an operative mortality ranging from 4 to 40%.[2] The prognosis in patients with coronary heart disease who do not undergo surgery is better than was formerly believed.[3] Many such patients live long and productive lives after the onset of the symptoms or signs of their heart disease. They might be expected, therefore, to benefit from even elective surgery if its hazards were negligible. Recent advances have made it worthwhile to review the status of the operative risk in patients with coronary heart disease.

MATERIAL

This report is based on a study conducted during the past five years on 5,778 surgical patients at the New England Center Hospital. The patients were divided into three groups. Group 1 consisted of 517 patients with known coronary heart disease. They had either a history of a recent or old myocardial infarction, with electrocardiographic changes or a definite history of angina pectoris. Eleven of these patients had had a myocardial infarction two days to seven weeks prior to surgery. Group 2 consisted of 1,107 patients with no history of coronary heart disease but with unequivocally abnormal electrocardiograms, e. g., ST segment changes, inverted T waves, bundle branch block, or auriculoventricular block. Group 3 consisted of 4,154 patients with no clinical evidence of heart disease and with normal electrocardiographic tracings.

Age Distribution.—The age distribution for the three groups is shown in table 1. This table reveals that patients with no heart disease were predominantly under

60 years of age while those in the other two groups were mainly over 60 years. The median age of group 3 was 10 years younger than that of the other two groups. This weighted distribution could be considered more favorable for the group without heart disease; however, the total death rate for each group was corrected for age.

Surgical Procedures.—The operations were classified as major and minor procedures. The major procedures consisted of intra-abdominal, intrathoracic, intracranial, extrapleural, neck, and renal operations. The minor procedures included those in which patients were anesthetized for such procedures as cystoscopy and excision of varicose veins. In each of the three groups about 60% of operations were major and about 40% were minor.

No heart disease	4,154	86	2.0
Total	5,778	140	2.4

RESULTS

Postoperative Mortality.—Postoperative mortality was analyzed from the standpoint of deaths from all causes as well as deaths from heart disease alone. Presumably only the cardiac deaths would be traceable to the preexisting heart disease. However, the possibility was considered that the incidence of postoperative deaths from noncardiac causes such as thromboembolic disease, atelectasis, and pneumonia might be higher in patients with cardiac disease. This was found not to be the case. Analysis of the total postoperative mortality from all causes is shown in table 2.

The over-all mortality rate in the three groups corrected for age, by reference to the group without heart disease, is shown in table 3. When a correction is made for the age factor, the observed total death rate after surgery in a group of patients with coronary heart disease is not statistically higher than the expected rate based on experience with the group of patients without heart disease.

There were 15 postoperative deaths from all causes in the series of 517 patients who had coronary heart disease, as shown in table 4. Of these 15, 6 were cardiac deaths. Five of these six were attributable to acute postoperative myocardial infarction. One was the result of acute pulmonary edema. Of the total of 517 patients with coronary heart disease, 11 were operated upon, of necessity, during the acute phase of the coronary heart disease, that is, within two days to seven weeks after an acute myocardial infarction. Two of these patients died of their cardiac disease after surgery. The deaths were due to myocardial infarction.

A comparative analysis of the cause of death in the three groups is shown in table 5. There were only 4 postoperative cardiac deaths in the 506 patients with chronic coronary heart disease. This was an incidence of 0.8% postoperative cardiac mortality and was approximately the same as that found in patients with abnormal electrocardiograms but with no history of cardiac pain. Of the seven postoperative cardiac deaths in the patients with abnormal electrocardiograms but without a history of cardiac pain, four were due to myocardial infarction and three to acute pulmonary edema. The four postoperative, presumably cardiac, deaths in patients with no clinical or electrocardiographic evidence of heart disease were caused by acute pulmonary edema. Acute pulmonary edema was considered a cardiac complication when there was no other recognized cause for this edema. The incidence of postoperative deaths from pulmonary embolus was not significantly influenced by the presence of heart disease, as may be noted in table 5. Postoperative cardiac complications, even major ones, did not always prove fatal in the patients with coronary heart disease; five survived a postoperative myocardial infarction and two recovered from acute pulmonary edema.

The postoperative death rate as the result of cardiac causes in all of the patients with preexisting coronary heart disease was 1.2%. It was only 0.8% if the patients with acute coronary heart diseases are excluded. This figure, 0.8%, compares with 0.1% in those patients without preoperative evidence of heart disease. The difference in the postoperative death rates between the two groups (operative patients with chronic coronary heart disease and those with no heart disease) was twice the standard error and is statistically significant. Although the difference is significant, a mortality rate of 0.8% is obviously not very great.

An analysis of the effect of operative time upon the deaths from all causes in patients with coronary heart disease showed that the length of time of anesthesia and surgery did not apparently influence the postoperative mortality rate. A good sampling of various types of anesthesia (spinal, inhalation, or local) revealed that there was no statistical difference in mortality rate related to the anesthetic technique and agent.

The influence of a specific elective major operative procedure was evaluated. Six per cent of the intra-abdominal procedures were cholecystectomies. A comparative analysis of the results following a cholecystectomy was made among the three groups of patients, and no significant difference in the postoperative results was demonstrated.

COMMENT

The factors associated with anesthesia that might make surgery more hazardous in patients with coronary disease include circulatory depression; a major effect of deep anesthesia is circulatory depression. Systemic arterial hypotension may be caused by direct myocardial depression during deep ether anesthesia [4] or a decrease in cardiac output and total peripheral resistance by ether, deep thiopental, cyclopropane, and high spinal anesthesia.[5] Such changes rarely occur during light levels of anesthesia. Another factor is respiratory depression; deep anesthesia is also accompanied by depressed ventilation. Toxic levels of carbon dioxide may ensue and predispose to cardiac arrhythmias and postoperative hypotension. A third is hypoxia, the most frequent consequence of oropharyngeal obstruction and laryngeal spasm during anesthesia. Other causes are a decrease in the inspired oxygen tension, arterial hypotension, depressed ventilation, and shock. Shock may lead to the development not only of a single but often of multiple fresh occlusions in the elderly patient, particularly in those with coronary atherosclerosis.[6] Miscellaneous factors include straining, bucking, and coughing during the induction of anesthesia, which may predispose to a reduction of the cardiac output and a decrease of the coronary flow.

One can avoid the conditions that might precipitate a coronary episode if the anesthetic induction is smooth and rapid, the level of anesthesia is light, and the patient's respiration is actively "controlled." Ventilation is controlled by compressing the anesthesia bag rhythmically so as to keep the mean airway pressure within physiological levels. A minimum of the primary anesthetic agent is required with this method; alveolar ventilation is kept within physiological range and the circulation is not depressed.

There are reports indicating that cyclopropane should not be administered to patients with coronary heart disease because it often produces arrhythmias. However, Johnstone [7] has demonstrated that the arrhythmias are caused not so much by the toxic effects of cyclopropane as by the deep levels of anesthesia produced by the cyclopropane resulting in decreased ventilation, carbon dioxide retention, and respiratory acidosis. Our own findings [8] are in agreement with those of Johnstone. The risk of cardiac mortality in patients with coronary heart disease undergoing surgery has been greatly lowered not only by improvement in the management of anesthesia but also by the notable advances in controlling infection, postoperative distention, thromboembolic disease, and disturbances in fluid and electrolyte balance.

A distinction should be made between coronary disease (coronary atherosclerosis without recognizable myocardial involvement) and coronary heart disease (cardiac pain or electrocardiographic changes or both). Coronary heart disease cannot be diagnosed until the appearance of cardiac pain and/or electrocardiographic changes that signify involvement of the heart muscle. Then the designation coronary heart disease is appropriate. Coronary disease in the form of atherosclerosis occurs in 50% of people between the ages of 45 and 50 [9] Even in the third decade the incidence of coronary atherosclerosis in presumably healthy individuals is not insignificant.[10] The incidence of coronary atherosclerosis in patients beyond 60 years of age is sufficiently high so that for all practical purposes, patients beyond 60 years of age should be dealt with as though they had coronary atherosclerosis.

Precautions designed to minimize the likelihood of myocardial infarction or coronary thrombosis should therefore be employed not alone when the clinical diagnosis of coronary heart disease can be made but when the diagnosis of coronary atherosclerosis can be suspected, i. e., in all patients beyond middle age. The problem of surgery and anesthesia in the patient with coronary disease is, therefore, inseparable from the problem of surgery in the elderly patient.

There were only four postoperative cardiac deaths in 506 patients with chronic coronary heart disease (0.8%); but, there were two deaths in only 11 patients with acute coronary heart disease (18.2%). The acute phase of coronary heart disease may be arbitrarily defined as extending over a period of three months and may begin either with an acute myocardial infarction, the onset of angina pectoris, or the worsening of preexisting angina pectoris. Only when it is absolutely necessary should patients be subjected to surgery within at least three months after evidence of the onset of acute coronary heart disease with or without infarction.

Since much can be done to make anesthesia and surgery relatively safe for patients with chronic coronary heart disease, how freely should they be subjected to surgery? Is the life expectancy of the patient with chronic coronary disease long enough to justify surgery when the risk is minimal? It now appears that, if a patient has survived his acute coronary heart episode and has made the transition into the chronic stage, his outlook for a long and productive life is good enough to warrant almost any operation that would otherwise be justifiable. It also appears that under such circumstances the risk of surgery is negligible insofar as cardiac deaths are concerned. This reassuring fact should make patients with coronary heart disease much less reluctant to submit to recommended surgery and much less frightened when they do.

SUMMARY

The postoperative mortality rate from all causes in 517 patients with evidence of coronary heart disease was 2.9% as compared to 2% in 4,154 patients with no clinical evidence of heart disease. The age of the patients studied ranged from 40 to 90 years. The death rate from cardiac causes following surgery was 0.1% in the group of patients with no recognizable heart disease. In 506 patients with chronic coronary heart disease the postoperative mortality was only 0.8%. There were 2 cardiac deaths (18.2%) in a group of 11 patients who required emergency operations during the course of their acute myocardial infarctions. There was no significant increase in the number of deaths caused by pulmonary embolus, surgical and anesthesia complications, or preexisting disease in patients with coronary heart disease. The operative risk is increased only slightly in patients with chronic coronary heart disease provided proper precautions are taken during and after anesthesia to prevent the impairment of coronary blood flow and of oxygenation.

CLINICAL NOTES

GOITER IN NEWBORN INFANT DUE TO MOTHER'S INGESTION OF PROPYLTHIOURACIL

Harold H. Aaron, M.D.
Samuel J. Schneierson, M.D.
and
Edward Siegel, B.S., New York

It is customary to classify congenital goiter into two groups: that occurring in endemic goiter regions and that occurring in nongoitrous areas in which there is no iodine lack.[1] In this presentation we are concerned with an instance of marked thyroid enlargement in a newborn infant in a nonendemic area. The etiology became clear when it was ascertained after birth that the mother had been continuously on a regimen of propylthiouracil for a period of 10 months preceding delivery.

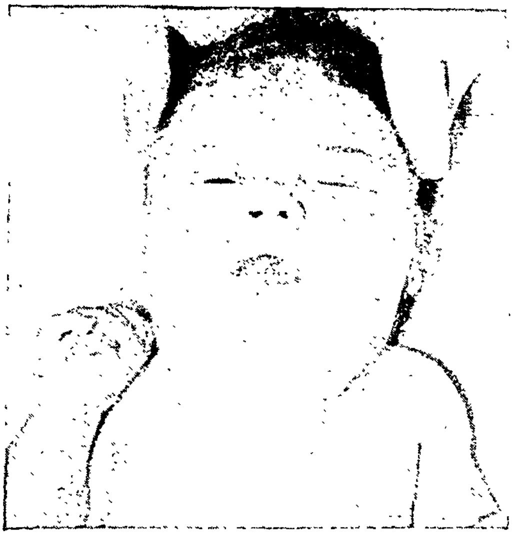

Fig. 1.—Appearance of infant with large neck mass.

REPORT OF A CASE

An infant, weighing 7 lb., 14 oz. (3,572 gm.) at birth, was delivered spontaneously, without obstetric difficulty, at Lebanon Hospital on Feb. 9, 1954. At once it was evident that the infant was in moderate respiratory distress, that there was marked enlargement of the neck anteriorly and bilaterally, and that the neck remained in a constantly hyperextended position. At birth the pertinent physical findings were as follows: slight, but consistent, inspiratory stridor; strong cry; no cyanosis but definite infracostal retraction on inspiration; face puffy; and neck hyperextended, evidently because of large neck mass (fig. 1). Palpation revealed this mass to be of unusually soft consistency and obviously made up of a right lobe, isthmus, and left lobe, with a general outline consistent with thyroid configuration. The entire neck, with the exception of its posterior surface, appeared to be hugely swollen, the right side more than the left.

From the Bertha C. Reiss Radioisotope Laboratory and the Department of Pediatrics, Lebanon Hospital.

[1] Wilkins, L.: The Diagnosis and Treatment of Endocrine Disorders in Childhood and Adolescence, ed. 1, Springfield, Ill., Charles C Thomas, Publisher, 1950, pp. 113, 115.

Because of the diagnosis of congenital goiter in this newborn infant consideration was given to the possibility of goitrogen ingestion by the mother during pregnancy. On inquiry it was ascertained that the mother had taken 300 mg. of propylthiouracil daily for a period of 10 months prior to the date of delivery. This had been prescribed by a physician for diarrhea thought to be due to ulcerative colitis. Information concerning ingestion of this drug had not been communicated to the attending obstetrician during pregnancy.

The infant was placed in an Isolette incubator and oxygen administered. After feedings, on a number of occasions, stridor and cyanosis became manifest but always subsided spontaneously within a few minutes. In general, improvement was progressive, so that at one week of age there was no longer any respiratory embarrassment after feedings. Formula intake, cry, skin color, temperature, muscular activity, stools, and urine output were normal at all times.

On Feb. 11, two days after birth, tracer studies were initiated after oral administration of 4 μc of radioactive iodine (I^{131}). Thyroid uptake at 5 hours was 77.3% of administered dose; at 24 hours and 48 hours the values were 78.6% and 72% respectively. Survey of the neck with a directional Geiger counter revealed that the radioisotope was localized in the neck mass previously described. This confirmed the clinical impression of great thyroid enlargement. Daily measurements over the mass were recorded until Feb. 24, 12 days after administration of the tracer dose. On that date the radioactivity in the thyroid, corrected for physical decay, was 47.4% of administered dose. On Feb. 14, three days after administration of I^{131}, 60 mg. of potassium thiocyanate were given by gastric tube. Measurements over the thyroid region were made four and eight hours later. These revealed only a slight decrease of I^{131} retention, from 78.8% to 69.7% at 8 hours.

On Feb. 9 (date of birth) x-ray studies disclosed the presence of a large neck mass causing tracheal compression (fig. 2*A*). Normal osseous centers were revealed in the wrists, knees, and feet in films taken on Feb. 16, 1954. On this date the serum protein-bound iodine level was 6 mcg. and the serum cholesterol level 155 mg. per 100 ml. The infant remained in the hospital for 22 days. During the first 12 days of life, despite adequate food intake, normal stools, and absence of vomiting, there was loss of weight from 7 lb., 14 oz. to 6 lb., 7 oz. (2,920 gm.), after which gain was progressive without change in formula. The thyroid mass diminished steadily in size, as was evident from physical and radiographic examinations. There was no clinical evidence of cretinism. On June 28, at age 4½ months, x-ray studies of the extremities revealed normal bone age. A second tracer study following oral administration of 4 μc of I^{131} revealed thyroid uptake of 2.7% at 5 hours and 2.5% at 24 hours. Physical examination on Nov. 10 at age 9 months disclosed only minimal right-sided thyroid enlargement. The infant was otherwise entirely normal, mentally and physically.

COMMENT

The goitrogenic effect of many antithyroid agents has been well established. Thus, the thiourea drugs, thiocyanate, various foods such as the Brassica family of plants (cabbage, turnip), and others have been well documented as goitrogens.[2] This action is believed to be dependent on the known hormonal relations between the thyroid gland and the anterior pituitary lobe. A decrease in the concentration of circulating thyroid hormone results in increased production of thyrotropic hormone by the anterior pituitary lobe, with resulting increased stimulation of the thyroid gland in all of its known functions, and hyperplasia and enlargement of the gland. Increased concentration of circulating thyroid hormone (hyperthyroidism, administration of thyroid) on the other hand has the inverse effect on the anterior pituitary lobe, decreasing its output of thyrotropic hormone. Whether the inhibitory action of an antithyroid agent is on the thyroid uptake of iodide (thiocyanate effect[3]) or on the synthesis of thyroid hormone (thiourea drugs[4]), the production and release of thyroid hormone are decreased. This decrease in circulating thyroid hormone results in hyperplasia and enlargement of the thyroid gland.

The fetal thyroid has been shown to begin functioning after 14 weeks of gestation.[5] At this time the gland becomes subject to the effect of maternally ingested propylthiouracil, which has been shown to traverse the placental barrier.[6] Reduced production of thyroid hormone by the mother may result in the fetus receiving less thyroxin than normally and this could contribute to the further compensatory stimulation of the fetal thyroid by its own anterior pituitary lobe. Since thyrotropic hormone probably does not pass through the placental barrier,[6a] increase of mother's thyrotropin production in all likelihood plays no part in congenital goiter.

Thiourea drugs block the enzymatic synthesis of thyroid hormone but do not affect the mechanism whereby the thyroid gland selectively takes up iodide from the plasma, as does thiocyanate. Administration of thiocyanate should result in discharge from the thyroid gland of I^{131} not yet organically bound, according to Stanbury.[7] This action of thiocyanate was not observed in the case reported. This may have been the result of either insufficient dosage of thiocyanate or the presence in the thyroid of only organically bound iodine. The I^{131} uptake in

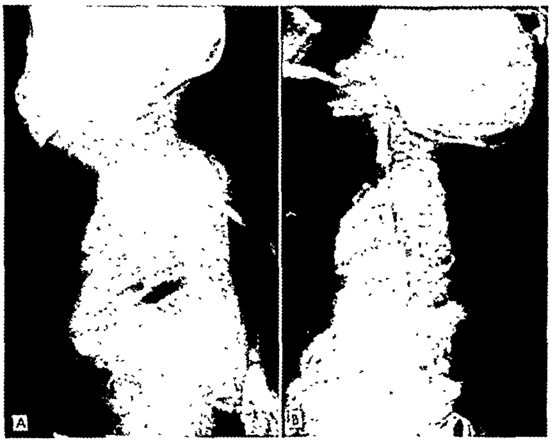

Fig. 2.—Roentgenograms showing *A*, large neck mass and tracheal distortion (Feb. 9, 1954); *B*, diminution in anteroposterior diameter of neck and normal configuration of trachea (March 1, 1954).

this infant cannot with certainty be regarded as abnormal. Van Middlesworth has reported even higher uptakes in normal newborn infants, and he considers these values to be indicative of "physiological hyperthyroidism in the newborn." [8]

Although no surgical intervention for relief of tracheal compression was necessary in this case, when there is danger of asphyxia in congenital goiter relief may be obtained by tracheotomy or resection of the thyroid isthmus. The latter appears to us to be preferable in neonatal life.

The danger of serious thyroid hypofunction developing in an infant with congenital goiter due to mother's ingestion of propylthiouracil during pregnancy appears to us to be very real. Other authors have felt likewise.[9] On the other hand, Astwood [10] has stated that antithyroid therapy can safely be continued throughout pregnancy without harm to either mother or child. Thus far the infant under consideration has had a normal developmental pattern. We intend to continue to observe this patient, particularly with regard to thyroid status.

SUMMARY

Goiter in a newborn infant, causing moderate respiratory distress at birth, resulted from mother's ingestion of propylthiouracil during pregnancy. Shortly after birth tracer studies with radioactive iodine (I^{131}) revealed high thyroid uptake values. Since even higher uptakes have been reported in normal newborn infants, these data cannot be regarded as abnormal. Fortunately, thyroid enlargement regressed progressively, and at one week of age there was no longer any respiratory embarrassment. The subsequent course of the infant has been one of normal physical and mental development.

Mitral Stenosis.—Disease of the mitral valve is the commonest manifestation of chronic rheumatic heart disease, and frequently the valve becomes sufficiently damaged so that significant stenosis occurs. This is a slowly developing process. Walsh and Bland have shown that it may take from five to 20 years for the clearcut clinical picture of mitral stenosis to develop after an initial attack of rheumatic fever, and in Bland and Jones' 20-year follow-up of patients with rheumatic fever, it is clear that mitral stenosis usually develops insidiously many years after rheumatic fever. In a total experience of about 850 operations on mitral stenosis, Harken and Ellis have had only nine patients under 20, the youngest being 18, in spite of the fact that the maximum incidence for rheumatic fever is between five and 15 years. In about a half of the adult patients with this disorder, no history suggesting rheumatic fever in the past is obtainable. It is apparent, therefore, that we do not yet understand the pathologic conditions that lead to the tight mitral stenosis found at operation and postmortem.—Ellis, Laurence B., M.D., The Selection of Patients with Mitral Stenosis for Valvular Surgery, *American Practitioner and Digest of Treatment*, August, 1955.

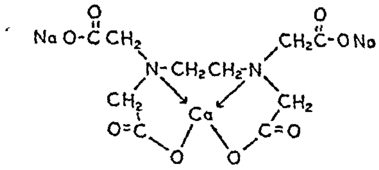
NEW AND NONOFFICIAL REMEDIES

Monographs and supplemental statements on drugs that appear in this column have been authorized by the Council for publication and inclusion in New and Nonofficial Remedies. They are based upon the evaluation of available scientific data and reports of investigations.

R. T. STORMONT, M.D., *Secretary.*

Edathamil Calcium-Disodium.—$C_{10}H_{12}CaN_2Na_2O_8$.—M.W. 374.29.—Calcium disodium (ethylenedinitrilo) tetraacetate.—Calcium disodium ethylenediaminetetraacetate.—The structural formula of edathamil calcium-disodium may be represented as follows:



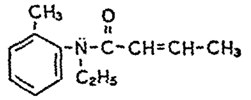
Actions and Uses.—Edathamil calcium-disodium is a cyclic complex chemical that exchanges its calcium for lead ions in the blood to form a more stable, virtually nonionic, water-soluble lead complex that is promptly excreted intact in the urine. It is therefore useful for the treatment of plumbemia in acute lead poisoning and for lead encephalopathy. It may also be used in cases of chronic lead poisoning if plumbemia is demonstrable. In vitro, the nearly water-insoluble acid, edathamil, forms more soluble salts with monovalent cations, which in turn combine with multivalent cations to form highly water-soluble, almost completely nonionic complexes, wherein each cation is joined by ordinary and coordinate valences. The compound formed from a monovalent cation is called a salt and the relatively stable complex formed from the further addition of a multivalent cation is referred to as a chelate; thus: edathamil calcium-disodium is the calcium chelate of the disodium salt of the acid, edathamil. In vitro, the displacement of calcium by lead to form the lead chelate is dependent upon the greater stability of the metallic complex. In vivo, the calcium-lead exchange reaction further depends upon the stronger bonds formed by the naturally occurring protein complexes of copper, iron, and cobalt in the body, which otherwise would be capable of displacing calcium. The relative stability of the calcium chelate is attributable to the strong affinity of the acid and its sodium salts for calcium, which saturates the complex. Thus, the calcium chelate retains its ability to entrap lead without producing a negative calcium balance. The resulting chelate of virtually nonionized lead serves to detoxify as well as to provide for excretion of that element.

Edathamil, its salts, and its chelates probably are not metabolized by the body. When salts of the acid are injected into normal warm-blooded animals, the calcium chelate is most commonly formed and most rapidly excreted intact in the urine. Intravenous injection of sodium salts thus can result in depletion of ionized calcium from the blood. If the rate of injection of sodium edathamil is sufficiently rapid, the rate of mobilization of calcium from the body reserves is exceeded, and hypocalcemic tetany may result. The calcium chelate has a low order of toxicity in experimental animals. There is a relatively wide margin between the fatal dose in animals and the corresponding therapeutic dose in man. Laboratory studies of animals receiving large doses have revealed no abnormalities, and clinical laboratory observations have shown no evidence of hematological or renal damage.

Dosage.—Edathamil calcium-disodium is administered by intravenous drip in either isotonic sodium chloride solution or 5% dextrose solution in a concentration not to exceed 3%, by diluting 5 cc. of a 20% solution (1 gm.) to 33 cc. The maximum dose per 4.5 kg. (10 lb.) of body weight is 0.17 gm. per hour, 0.33 gm. per day, or 1.67 gm. per week. The maximum dose per course of treatment is 2.5 gm. per 4.5 kg. (10 lb.) of body weight. It is advisable not to exceed two such courses, allowing seven days of rest between them. Interrupted courses are considered preferable to continuous therapy, and they should be in accordance with demonstrable increased titer of lead in the blood. A finding of more than 0.05 mg. of lead per 100 cc. of whole blood or 0.1 mg. per liter of a 24 hour specimen of urine is considered pathognomonic of lead poisoning.

Riker Laboratories, Inc., cooperated by furnishing scientific data to aid in the evaluation of edathamil calcium-disodium.

Crotamiton.—$C_{13}H_{17}NO$.—M.W. 203.27.—N-Ethyl-*o*-crotonotoluide.—The structural formula of crotamiton may be represented as follows:



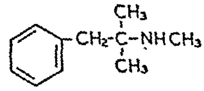
Actions and Uses.—Crotamiton is a sarcopticide useful for topical application in the treatment of scabies. Although it exhibits some bacteriostatic and fungistatic properties, there is inadequate evidence at present to justify claims for such action or for use in place of recognized local anti-infective agents when these may be indicated for the management of secondary infection.

Sensitivity or intolerance to crotamiton itself has been rarely encountered; mild erythema observed in some cases has been attributed to its cream base. Although crotamiton apparently has a low index of sensitization, physicians should be aware that such reactions may be encountered. In the presence of acute vesicular dermatitis crotamiton should not be used, for it may produce a burning sensation and act as a primary irritant. Crotamiton is of low toxicity in animals. Systemic effects have not been observed clinically.

Dosage.—Crotamiton is applied topically in a cream or lotion base containing 10% of the agent. In the treatment of scabies, it is applied to the skin by gentle massage in an amount sufficient to cover the entire body (excluding the head); 30 gm. is usually sufficient for a single application. Preliminary bathing is not necessary, but if this is done the skin should be thoroughly dry before applying crotamiton. A second application 24 hours later is advised to assure complete eradication of the mites; occasionally, a third application may be required. A cleansing bath should be taken 48 hours after the last application and bed and body clothing should be completely changed to prevent reinfection. Other members of the family should be examined for the disease.

Geigy Pharmaceuticals, Division of Geigy Chemical Corporation, cooperated by furnishing scientific data to aid in the evaluation of crotamiton.

Mephentermine.—$C_{11}H_{17}N$.—M.W. 163.26.—N,α,α-Trimethylphenethylamine.—The structural formula for mephentermine may be represented as follows:

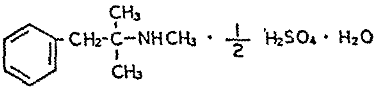


Actions and Uses.—Mephentermine is a sympathomimetic amine that shares the vasoconstrictor action common to such agents. It is sufficiently volatile for inhalation to produce vasoconstriction of the congested nasal mucous membrane, being about one-half as active in this respect as amphetamine. Mephentermine is less toxic than amphetamine when injected into experimental animals, and its pressor action resembles that of ephedrine rather than epinephrine; its cerebral stimulant action is much less than that of amphetamine and methamphetamine. It does not significantly relax smooth muscle. Local application of a 1% solution dilates the pupil. Mephentermine is used only by inhalation as a nasal decongestant to provide temporary relief in the treatment of acute or chronic rhinitis, allergic or nonallergic rhinitis, vasomotor rhinitis, and sinusitis.

Dosage.—Mephentermine is applied to the nasal mucosa by means of an inhaler containing a total of 250 mg. of the drug. Two inhalations through each nostril are recommended as a single dose. This provides a variable amount chiefly dependent upon the depth of inhalation. The contents of the inhaler is sufficient to last about three months from the time of initial use.

Wyeth Laboratories, Inc., cooperated by furnishing scientific data to aid in the evaluation of mephentermine.

Mephentermine Sulfate, U. S. P.—$C_{22}H_{34}N_2.H_2SO_4.$-$2H_2O$. — M.W. 460.64. — N,α,α-Trimethylphenethylamine sulfate.—The structural formula for mephentermine sulfate may be represented as follows:



Actions and Uses.—Mephentermine sulfate is a soluble salt of a sympathomimetic amine base and exhibits the vasoconstrictor action characteristic of such compounds. The solution is applied topically as a nasal decongestant in the treatment of vasomotor rhinitis, acute or chronic rhinitis, allergic or nonallergic rhinitis, and sinusitis. For other actions, see the monograph on mephentermine.

Dosage.—A 0.5% solution of the drug in isotonic sodium chloride solution is topically applied to the nasal mucosa by means of a dropper. The recommended schedule is two or three drops in each nostril every 4 hours or as required to temporarily relieve nasal congestion.

Wyeth Laboratories, Inc., cooperated by furnishing scientific data to aid in the evaluation of mephentermine sulfate.

MEETINGS OF THE HOUSE OF DELEGATES

The policies of the American Medical Association are determined by the House of Delegates. Twice a year it meets and considers the reports and resolutions introduced by members of the House, Board of Trustees, special committees, and standing committees. There is no body more influential in American medicine nor more democratic in action. All resolutions and all reports after presentation are referred to a committee for study, during which time anyone may appear before the committee to ask questions or state opinions. After the hearings a committee prepares its recommendations, which are studied by the House and accepted, modified, or rejected. Even during this time of deliberation by the House, members of the House, or others if granted permission by the Speaker, may comment on the proposal.

During the past several years there has been an increasing number of physician members of the A. M. A. who have attended meetings of the House and of its reference committees. This has resulted in a better appreciation of how the policies of the Association are formed, but, of equal importance, it also has provided additional information for the committee members. If no one bothers attending a committee meeting there should be no complaint if the committee lacks important information and errs in its decision. Most of the committee members are well informed in the subjects that are presented to them for study, but even so they appreciate all the help they can receive. Undoubtedly there are many members of the Association who disagree on occasion with a decision of the House of Delegates, but how many of these critics have taken the time to watch the House in action or have volunteered comments even though they have been present for the meeting of the Association. The scientific program of the Association is important and helpful to the man in practice, but so are the many problems facing the House at each session. In fact, during the next few years, as has been particularly true for the last decade, the so-called nonscientific problems may have a more far-reaching influence on medical practice than the development of a new drug or surgical technique.

At the forthcoming meeting in Boston, November 29 to December 2, there will be opportunity for members of the Association to observe firsthand how their organization functions. They should make use of this opportunity, and if they cannot be present in Boston they can be at subsequent meetings in Chicago, Seattle, New York, San Francisco, or Atlantic City, or wherever the Association may meet during the next several years. Letters between physicians and elected officials of the Association can be helpful, but personal contact usually is far more helpful to everyone.

INTERNATIONAL CERTIFICATES OF VACCINATION

During 1954, 452,049 persons traveled outside the United States, not counting the thousands who daily cross the Canadian or Mexican borders. The International Certificates of Vaccination form that physicians are called on to complete whenever a person is vaccinated for international travel is an important document. A person can be quickly processed by quarantine officers here and abroad when his vaccination certificate contains complete information and is properly authenticated.

The vaccinating physician can help in this procedure by always using the International Certificates of Vaccination form to record complete immunization data and by instructing the prospective traveler to have the certificate authenticated by the local or state health officer. The health officer can speed the process by using his official stamp or seal to authenticate the certificate. If the health officer does not have either, the United States Public Health Service suggests that he have a stamp made that includes the term "health officer" and the name and address of the health department. The act of applying the stamp to the certificate is required by international agreement for the purpose of attesting to the fact that the immunizing physician is a practicing physician within the area, thus reducing the possibility of fraudulent certificates being issued. The certificate is not valid without this approved stamp, and without it the traveler may be exposed to delay or other difficulties.

The International Certificates of Vaccination form is given to prospective travelers with the passport application. If the person is traveling on a tourist card he may obtain a certificate from the local health department or purchase one from the Superintendent of Documents, Government Printing Office, Washington, D. C., for 5 cents. Most travel agencies and automobile clubs also have these certificates. The cooperation of all those concerned with the issuance of a valid certificate to the traveler will assist in helping the United States to maintain its present morbidity rate of zero for smallpox in spite of the disease being present in other areas of the world.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

We, the American Medical Association, which after all is the American medical profession, have often been severely criticized because it is said that we are always against something and that we never propose anything constructive in a legislative way. To those of us who have had experience with legislators and legislation, particularly at the national level, this has sometimes seemed to be true. Yet there really has been little we could do about it for the simple reason that we represent an extremely conservative organization of individual thinkers and doers and it is often difficult to arrive at a unanimity of minds even over the conference table. It would also be a foolish thing for us to sponsor legislation of any kind because of the dangers of the amendments that might be tacked on an A. M. A.-sponsored bill that would either nullify the intent of the bill itself or because of the bill's popularity might create a law that we would regret. Such a bill, amended, would be forever tagged as A. M. A.-sponsored legislation. This would of course be incorrect but would serve as high-powered ammunition in the hands of those people who vocally and violently oppose the free enterprise system. There have been bills on health matters written and presented by some legislators without once consulting representatives of the A. M. A. Many of these bills are so worded that they are ambiguous. We know what is in the minds of the legislator or even at times the administration and how the bill would be interpreted by the authorities who have sponsored the bill, but some future Congress or administration might be tempted to make an entirely different interpretation from that originally intended. With the Washington Office filled with medical and health information available to those who wish to write health legislation it seems incredible that it is not more often used for the purpose for which it was created; namely, to supply information to anyone on health matters. Good health legislation is vitally important to our people. It should be written in clear unmistakable language that is not subject to dual interpretation. It should protect both the public, the receiver of medical services, and the physicians, the purveyors of the services.

Every bill that is written is carefully scrutinized by our office in Washington, by the Chicago office of the A. M. A., and by our Committee on Legislation. After careful reading and study the decision is made to support or to oppose. We also take no action for or against many legislative proposals after thorough discussions. Quite frequently we are for certain bills in principle, and often we go before congressional committees to suggest changes in bills when we feel that such changes are necessary. This is not only our right but our duty. It is likewise the duty of all groups and individual citizens. It is our particular duty when any form of health legislation is proposed.

By tradition the medical profession has been trained to move ahead cautiously and slowly; each progressive step in our scientific work is examined and reexamined before we accept it. This training of necessity makes us extremely cautious in supporting legislation that it seems to us might not be as good as the legislative experts think it will. We are individualists, now, and I am afraid forevermore, but we no longer take our duties as citizens lightly and we feel that we have the right and duty to express our opinions before congressional committees without being abused or slandered. Too often chairmen and members of committees have had a field day at the expense of decent American physicians appearing before them, particularly if we are opposing someone's favorite bill. These men are our representatives, and, whether they agree or disagree with us, they serve in their positions as elected representatives of all of us who are American citizens. They should be our servants, not try to be our masters.

It therefore behooves every physician to try and know what legislation he wants the A. M. A. to support or oppose. We, your elected officers, have very receptive and open minds on the subject. We do the very best we can when these various legislative problems arise. We try our best to present that which we honestly and sincerely believe to be the wish and desire of the majority of our members. I often think how much time those of us who are your elected officials spend trying our best to represent you in the nation's capitol. I wonder if it would not be a good idea for some of the rest of us to occasionally go to Washington as appointed representatives of the Association. A good idea might be to have committees composed of the family physicians of the senators and representatives to appear for or against some of these bills. Congressmen seem to respect their own doctors above everyone else, and they might listen to them if they were to appear before them. Is it not worth trying?

Elmer Hess, M.D.,
Erie, Pa.

HISTORICAL AND METROPOLITAN BOSTON

Metropolitan and historical Boston, with its more than 2,500,000 people, is one of the most interesting areas in the world to visit. Founded in 1630 by English Puritans of the Massachusetts Bay Colony, it retains today the charm of both the old world and the new. The crooked and narrow ways that once were cow paths are still there amidst modern, broad, and beautiful avenues, and skyscrapers have been built around, but not over, the many historical shrines. Boston has been affectionately called "the Athens of America," "the city of yesterday and today," and "the hub of the universe," because of the cultural, spiritual, commercial, and historical assets present in this area. There is enough to see and to do to keep one busy for days. There is Boston Common, a tract of some 50 acres in the heart of the city, which was set aside in 1634 for "feeding the cattell" and "a trayning field." There in colonial times British troops were quartered, and from what is now Park Square the British set out for Lexington, only a short distance by automobile along the route that Paul Revere rode to warn the farmers that the British were coming. The home in Boston where Paul Revere lived for 30 years is open to the public on weekdays from 10 to 4, as is also Old North Church, in whose spire lanterns were hung to signal Revere that the British were coming. Here is the Old South Meeting House, where citizens gathered to plan the Boston Tea Party. Here is Fanueil Hall, "the cradle of Liberty," and the burying ground where Paul Revere, John Hancock, Benjamin Franklin's parents—victims of the Boston massacre, and other famous persons are buried. Bunker Hill Monument marks the site of the battle on June 17, 1775. Here are the homes of Longfellow, James Russell Lowell, John Adams, and John Quincy Adams. A few miles away in Salem is the House of Seven Gables and near Concord the Wayside Inn, owned by Nathaniel Hawthorne and later the girlhood home of Louisa M. Alcott. Across from the City Hall Annex in Boston a tablet marks the site of the old printing office where Benjamin Franklin learned his trade. A few miles from Boston are many other historic places—Plymouth Rock; Cape Cod; the fishing port of Gloucester; Marblehead, a typical old New England town. In Mount Auburn Cemetery in Cambridge, sometimes called the poets' cemetery, are buried Oliver Wendell Holmes, Henry Wadsworth Longfellow, James Russell Lowell, Charles Sumner, Edward Everett, Louis Agassiz, and Phillips Brooks.

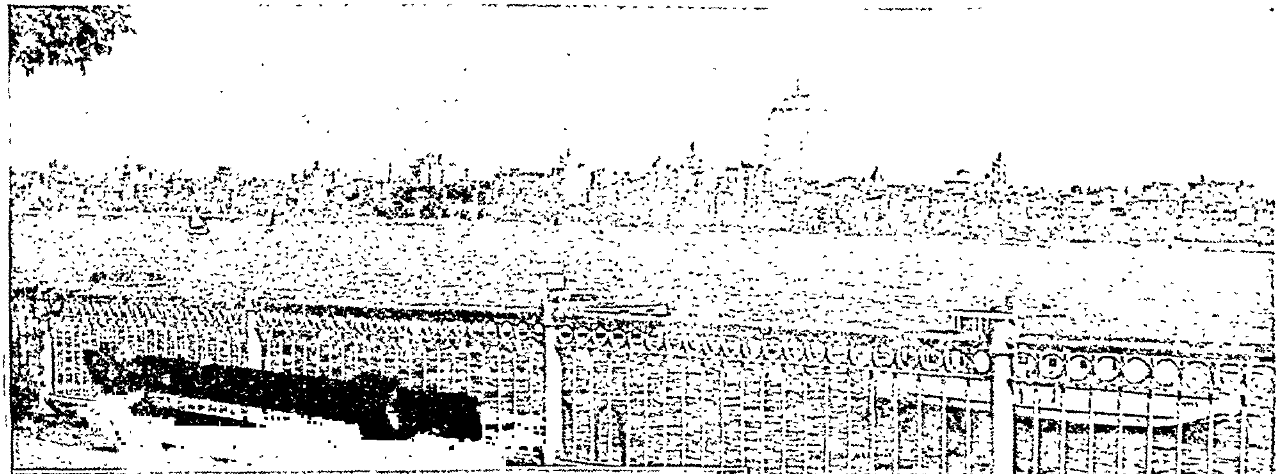
Boston has been said to be the cultural center of America. It is the only industrial city east of the Pacific Coast in which more than 50% of the adult population has attended high school. Among its 200 schools, colleges, and universities are Harvard, Massachusetts Institute of Technology, Boston University, Wellesley, Radcliffe, Tufts, the New England Conservatory of Music, the Massachusetts School of Art, Northeastern, and Boston College. There are 224 public libraries with more than 4 million books. The Boston Public Library alone has 2 million volumes. The Boston Medical Library has one of the finest collections of 16th century medical documents and curios in existence. American education is said to have originated here in 1635 when the oldest free public school in the nation, the Boston Public Latin School, was founded.

Boston has three medical schools, Harvard, Tufts, and Boston University School of Medicine; many research institutes; and numerous nurses' training facilities. Here was organized the first local health department in America, with Paul Revere as its first chairman. The first newspaper was published in Boston in 1690, the first railway built in 1825 and the first subway in 1895; the world's first telephone call was made here in 1876; and the first successful surgical operation performed with the patient under ether anesthesia was done in the Massachusetts General Hospital in 1846.

Out of the reknown Boston Symphony Orchestra have grown the Boston Pops Orchestra, which holds outdoor concerts on the Charles River Esplanade; the Boston Symphony School at Tanglewood in the Berkshires; and the New England Opera Theatre. Many art clubs flourish in this area. The Boston Museum of Fine Arts for nearly 80 years has had one of the nation's most comprehensive collections.

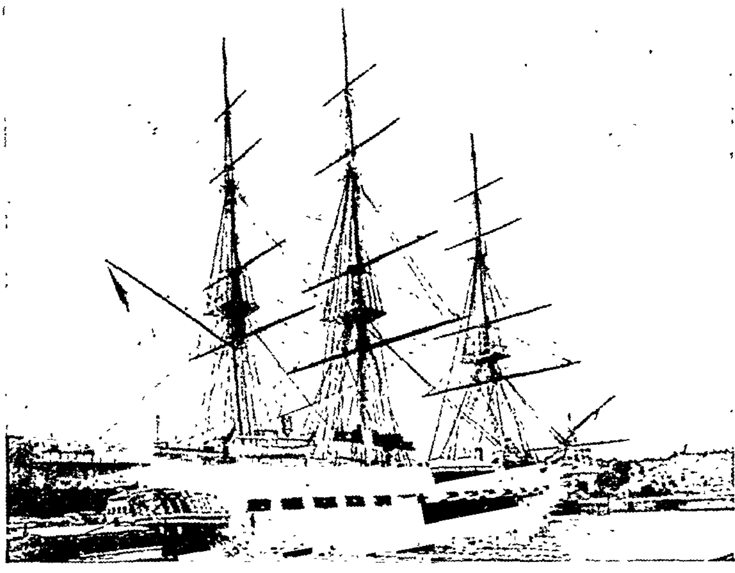
Boston is the world's leading leather market. About one-third of the fresh and frozen fish consumed in the United States comes from metropolitan Boston, some of the fishing centers being Gloucester, New Bedford, and Cape Cod. Boston is the wool center of the world. Through its docks and railyards and in its warehouses more than 70% of all the wool consumed in the United States is bought and sold.

The average mean temperature is 57.6 degrees. The average relative humidity is 68%, and 65% of the days are partially or fully sunlit. On arrival by air, train, bus, or motorcar, many fine restaurants await the visitor. While sea food is a specialty, all types of delicacies prepared by old masters are available. Come to the Boston Clinical Meeting and enjoy also the food and entertainment.

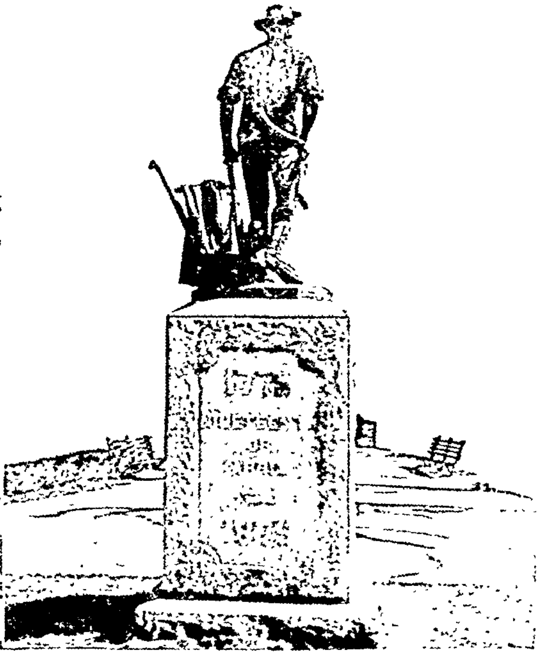


View of Boston across the Charles River from Cambridge.

Left, statue of Paul Revere. In the background is the Old North Church, where lanterns were hung to inform Paul Revere that the British were on their way to Lexington and Concord.

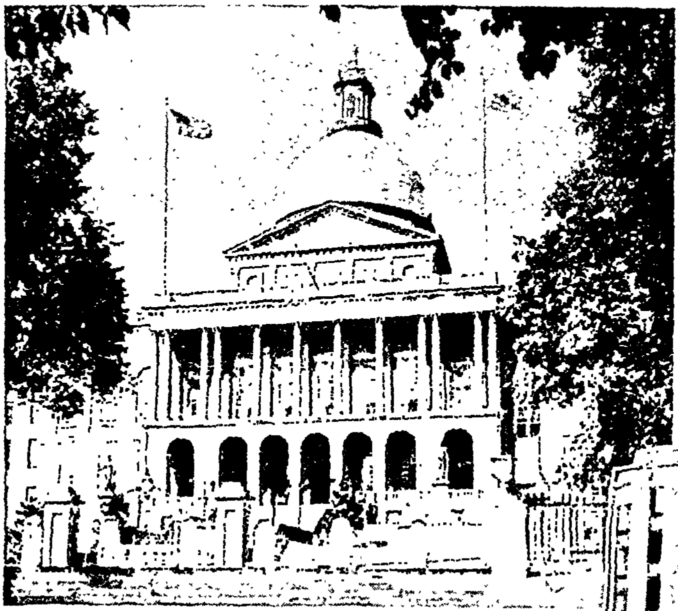


Below left, "Old Ironsides," which fought nobly in the War of 1812 and now rests in the Charlestown Navy Yard in Boston.



Below, statue of the Minute Man in Concord, where "the first shot that was heard around the world" was fired.

HISTORICAL AND METROPOLITAN BOSTON

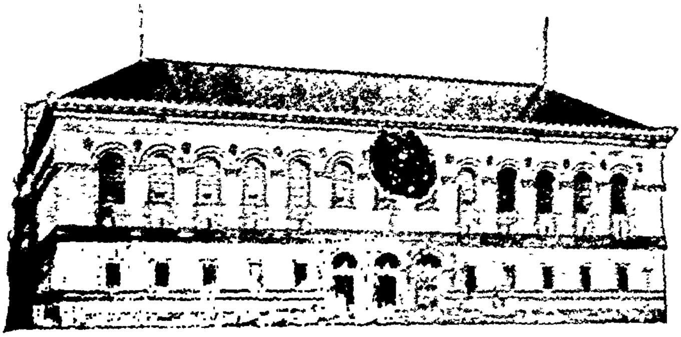


Above, the golden-domed capitol of Massachusetts on Beacon Hill, former site of residence of John Hancock, first signer of the Declaration of Independence.

Right, the Massachusetts General Hospital.

Right, scene along the Boston Common, a tract containing nearly 50 acres, where the British soldiers mustered before the Battle of Bunker Hill.

Below, the Boston Public Library, with a 2 million volume collection, is also famous for its mural paintings.



THE CLINICAL MEETING

AMERICAN MEDICAL ASSOCIATION

Boston, Nov. 29—Dec. 2, 1955

OFFICIAL CALL

TO THE OFFICERS AND MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

The Clinical Meeting of the American Medical Association will be held in Boston, Nov. 29-Dec. 2, 1955.

The House of Delegates will convene at 10 a. m., Tuesday, Nov. 29, in the Ballroom of the Hotel Statler. In the House the representation of the various constituent associations for the clinical meeting in 1955 is as follows:

Alabama	2
Arizona	1
Arkansas	2
California	13
Colorado	2
Connecticut	3
Delaware	1
District of Columbia	2
Florida	3
Georgia	3
Idaho	1
Illinois	10
Indiana	4
Iowa	3
Kansas	2
Kentucky	2
Louisiana	2
Maine	1
Maryland	2
Massachusetts	6
Michigan	6
Minnesota	4
Mississippi	2
Missouri	4
Montana	1
Nebraska	2
Nevada	1
New Hampshire	1
New Jersey	6
New Mexico	1
New York	18
North Carolina	3
North Dakota	1
Ohio	8
Oklahoma	2
Oregon	2
Pennsylvania	11
Rhode Island	1
South Carolina	2
South Dakota	1
Tennessee	3
Texas	7
Utah	1
Vermont	1
Virginia	2
Washington	3
West Virginia	2
Wisconsin	4
Wyoming	1
Alaska	1
Hawaii	1
Isthmian Canal Zone	1
Puerto Rico	1

The scientific sections of the American Medical Association, the Medical Corps of the Army, the Medical Corps of the Navy, the Medical Corps of the Air Force, the Public Health Service, and the Veterans Administration are entitled to one delegate each.

The scientific meetings and the scientific and technical exhibits will be held in Mechanics Hall.

The Opening General Session will start at 10:30 a. m., Tuesday, Nov. 29.

The Scientific Program will open Tuesday, Nov. 29, starting at 1:00 p. m., and will continue throughout the afternoon of that day. The program will continue on Wednesday and Thursday mornings and afternoons, Nov. 30 and Dec. 1, and on Friday morning, Dec. 2, closing at 12 noon.

The Registration Bureau, which will be located in Mechanics Hall, will be open from 8:00 a. m. until 5:30 p. m., Tuesday, Wednesday, and Thursday, Nov. 29 to Dec. 1, and from 8:00 a. m. to 12:00 noon, Friday, Dec. 2.

Elmer Hess, President.
E. Vincent Askey, Speaker, House of Delegates.
George F. Lull, Secretary.

OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION, 1955-1956

President—Elmer Hess, Erie, Pa.

President-Elect—Dwight H. Murray, Napa, Calif.

Vice President—Millard D. Hill, Raleigh, N. C.

Secretary and General Manager—George F. Lull, Chicago.

Assistant Secretary—Ernest B. Howard, Chicago.

Treasurer—J. J. Moore, Chicago.

Speaker, House of Delegates—E. Vincent Askey, Los Angeles.

Vice Speaker, House of Delegates—Louis M. Orr, Orlando, Fla.

Editor—Austin Smith, Chicago.

Business Manager—Thomas R. Gardiner, Chicago.

Board of Trustees—J. P. Price, Florence, S. C., 1956; J. R. Reuling, Bayside, N. Y., 1957; J. R. McVay, Kansas City, Mo., 1957; E. S. Hamilton, Kankakee, Ill., 1958; G. Gundersen, Chairman, LaCrosse, Wis., 1958; D. B. Allman, Atlantic City, N. J., 1959; F. J. L. Blasingame, Wharton, Texas, 1959; L. W. Larson, Bismarck, N. D., 1960; T. P. Murdock, Meriden, Conn., 1960; the President and the President-Elect.

STANDING COMMITTEES OF THE HOUSE OF DELEGATES

Judicial Council—W. F. Donaldson, Bakerstown, Pa., 1956; H. L. Pearson Jr., Chairman, Miami, Fla., 1957; G. A. Woodhouse, Pleasant Hill, Ohio, 1958; J. M. Hutcheson, Richmond, Va., 1959; L. A. Buie, Rochester, Minn., 1960; G. F. Lull, Secretary, Chicago.

Council on Medical Education and Hospitals—G. A. Caldwell, New Orleans, 1956; J. W. Cline, San Francisco, 1956; F. D. Murphy, Lawrence, Kan., 1957; H. G. Weiskotten, Chairman, Skaneateles, N. Y., 1957; V. Johnson, Rochester, Minn., 1958; L. S. McKittrick, Brookline, Mass., 1958; C. T. Stone Sr., Galveston, Texas, 1959; W. A. Bunten, Cheyenne, Wyo., 1959; J. M. Faulkner, Boston, 1960; H. English, Danville, Ill., 1960; E. L. Turner, Secretary, Chicago.

Council on Medical Service—C. E. Wertz, Buffalo, 1956; R. L. Novy, Detroit, 1957; R. B. Chrisman Jr., Miami, Fla., 1958; A. C. Scott Jr., Temple, Texas, 1958; J. D. McCarthy, Chairman, Omaha, 1959; H. B. Mulholland, Charlottesville, Va., 1960; W. B. Martin, Norfolk, Va., E. Hess, Erie, Pa.; D. B. Allman, Atlantic City, N. J.; Mr. T. A. Hendricks, Secretary, Chicago.

Council on Constitution and Bylaws—L. A. Buie, Chairman, Rochester, Minn., 1956; J. Stevenson,* Tulsa, Okla., 1957; S. H. Osborn, Hartford, Conn., 1958; F. S. Winslow, Rochester, N. Y., 1959; B. E. Pickett Sr., Carrizo Springs, Texas, 1960; E. S. Hamilton, Kankakee, Ill.; the President and the Speaker and Vice Speaker of the House of Delegates.

STANDING COMMITTEES OF THE BOARD OF TRUSTEES

Council on Pharmacy and Chemistry—C. A. Dragstedt, Chicago, 1955; I. Starr, Philadelphia, 1955; J. Hayman, Boston, 1955; E. M. K. Geiling, Chicago, 1956; E. M. Nelson, Washington, D. C., 1956; H. K. Beecher, Boston, 1956; T. Sollmann, Chairman, Cleveland, 1957; J. P. Leake, Washington, D. C., 1957; A. C. Curtis, Ann Arbor, Mich., 1957; W. C. Cutting, San Francisco, 1958; O. O. Meyer, Madison, Wis., 1958; M. H. Seevers, Ann Arbor, Mich., 1958; T. M. Brown, Washington, D. C., 1958; J. Stokes Jr., Philadelphia, 1959; P. H. Long, Brooklyn, 1959; W. G. Workman, Bethesda, Md., 1959; H. Eagle, Bethesda, Md., 1959; R. T. Stormont, Secretary, Chicago.

Council on Scientific Assembly—L. W. Larson, Bismarck, N. D., 1955; C. A. Lincke, Carrollton, Ohio, 1955; M. E. DeBakey, Houston, Texas, 1956; S. P. Newman, Denver, 1957; J. R. McVay, Kansas City, Mo., 1957; H. R. Viets, Boston, 1958; C. H. Phifer, Chicago, 1958; S. P. Reimann, Philadelphia, 1959; A. McMahon, Chairman, St. Louis, 1959; T. G. Hull, Secretary, Chicago.

Council on Rehabilitation—O. Glasser, Cleveland, 1955; S. Warren, Boston, 1955; D. Vail, Chicago, 1955; F. R. Ober, Boston, 1956; D. M. Lierle, Iowa City, 1956; W. W. Coblentz, Washington, D. C., 1957; G. M. Piersol, Philadelphia, 1957; M. A. Bowie, Swarthmore, Pa., 1958; A. L. Watkins, Boston, 1958; W. J. Zeiter, Cleveland, 1958; F. H. Krusen, Chairman, Rochester, Minn., 1959; A. C. Cipollaro, New York, 1959; F. Butte, Dallas, Texas, 1959; R. E. DeForest, Secretary, Chicago.

Council on Foods and Nutrition—C. A. Smith, Boston, 1955; R. Jackson, Columbia, Mo., 1956; G. R. Cowgill, New Haven, Conn., 1956; W. H. Griffith, Los Angeles, 1957; W. J. Darby, Nashville, Tenn., 1958; C. A. Elvehjem, Madison, Wis., 1958; J. B. Youmans, Nashville, Tenn., 1958; L. A. Maynard, New York, 1959; G. A. Goldsmith, New Orleans, 1959; C. S. Davidson, Chairman, Boston, 1959.

Council on Industrial Health—L. E. Hamlin, Chicago, 1955; R. A. Kehoe, Cincinnati, 1955; W. P. Shepard, Chairman, New York, 1956; M. N. Newquist, New York, 1956; P. S. Richards, Salt Lake City, 1957; J. H. Sterner, Rochester, N. Y., 1957; R. T. Johnstone, Los Angeles, 1958; L. C. McGee, Wilmington, Del., 1958; C. F. Shook, Toledo, Ohio, 1958; J. N. Gallivan, East Hartford, Conn., 1959; V. C. Baird, Houston, Texas, 1959; O. A. Sander, Milwaukee, 1959; C. M. Peterson,* Secretary, Chicago.

---

* Deceased.

Council on National Defense—A. A. Brindley, Toledo, Ohio, 1955; C. P. Hungate, Kansas City, Mo., 1955; S. L. Warren, Los Angeles, 1956; H. B. Wright, Cleveland, 1956; R. A. Benson, Bremerton, Wash., 1957; P. H. Long, Brooklyn, 1957; R. L. Sensenich, South Bend, Ind., 1958; H. C. Lueth, Evanston, Ill., 1958; H. S. Diehl, Chairman, Minneapolis, 1959; R. L. Meiling, Columbus, Ohio, 1959; Mr. F. W. Barton, Secretary, Chicago.

Council on Rural Health—F. A. Humphrey, Ft. Collins, Colo., 1955; N. H. Gardner, E. Hampton, Conn., 1955; A. T. Stewart, Lubbock, Texas, 1956; H. A. Randel,* Fresno, Calif., 1956; W. J. Weese, Ontario, Ore., 1957; W. A. Wright, Williston, N. D., 1957; F. S. Crockett, Chairman, Lafayette, Ind., 1958; G. F. Bond, Bat Cave, N. C., 1958; C. S. Mundy, Toledo, Ohio, 1959; C. R. Henry, Little Rock, Ark., 1959; Mrs. A. Hibbard, Secretary, Chicago.

Council on Mental Health—F. M. Forster, Washington, D. C., 1955; H. T. Carmichael, Chicago, 1956; M. R. Kaufman, New York, 1957; L. H. Bartemeier, Chairman, Baltimore, 1958; W. H. Baer, Peoria, Ill., 1958; F. J. Gerty, Chicago, 1958; L. H. Smith, Philadelphia, 1959; G. E. Gardner, Boston, 1959; R. J. Plunkett, Secretary, Chicago.

Committee on Legislation—R. B. Chrisman Jr., Miami, Fla., 1955; J. L. Ludwig, Los Angeles, 1955; D. B. Allman, Chairman, Atlantic City, N. J., 1956; M L. Phelps, Denver, 1956; J. D. McCarthy, Omaha, 1957; J. E. McDonald, Tulsa, Okla., 1957; D. G. Smith, Nashua, N. H., 1958; H. English, Danville, Ill., 1958; C. Bailey, Harlan, Ky., 1959; C. L. Palmer, Harrisburg, Pa., 1959; Mr. R. G. Van Buskirk, Secretary, Chicago.

The Secretary, Assistant Secretary and Editor are ex officio members of all Standing Committees.

* Deceased.

REGISTRATION

The Registration Bureau will be located at the entrance to Mechanics Hall and will be open all day Tuesday, Wednesday, and Thursday, Nov. 29 and 30, and Dec. 1, and until noon on Friday, Dec. 2.

An information bureau will be operated in connection with the Registration Bureau.

Who May Register

Members—Active, Affiliate, Associate, Service, and Honorary—and invited guests may register for attendance at meetings.

Active members in good standing in the American Medical Association are those members of component county medical societies and of constituent state and territorial medical associations whose names are officially reported for enrollment to the Secretary of the American Medical Association by the secretaries of the constituent medical associations and who have paid their annual American Medical Association membership dues, which this year are $25, to be paid through their constituent medical associations.

Residents, interns, senior medical students, and registered nurses will find special registration cards to fill in on tables near the registration windows. These should be presented, at the window indicated, together with a card or letter signed by the superintendent of the hospital where they are located, or the dean of the medical school they attend.

Register Early

The Registration Bureau will be open at 8:00 a. m., on Tuesday, Nov. 29. Members are urged to take advantage of this early opening.

The names and Boston addresses of those who register will be included in the *Daily Bulletin,* and this will enable visiting physicians to find friends who have registered.

Suggestions That Will Facilitate Registration

Members who have Advance Registration Cards with pocket cards can be registered with little or no delay. They should fill in the following information on the cards prior to their registration:

Hotel, number of guests, and signature.

Present filled in card with your American Medical Association Membership pocket card at windows marked "Advance Registration." Your pocket card will be returned to you, and you will receive a badge and a copy of the Official Program.

Members without Advance Registration Cards will be given blank cards to fill out, and clerks will be on hand to direct them to the proper windows for registering. They will receive a badge and a copy of the Official Program.

Registration for General Officers and Delegates at the Hotel Statler

General officers of the American Medical Association and members of the House of Delegates may register for the Scientific Assembly at the entrance to the Ballroom at the Hotel Statler. This arrangement is made for the convenience of members of the House of Delegates, which will convene on Tuesday morning at 10 o'clock in the Ballroom of the Hotel Statler. Delegates are requested to register for the Scientific Assembly before presenting credentials to the Reference Committee on Credentials of the House of Delegates. Registration of delegates for the Scientific Assembly will begin at 8 o'clock Tuesday morning, Nov. 29, and delegates are urged to register early so that all members of the House of Delegates may be seated in time for the opening session of the House.

If any delegate or officer is in Boston on Sunday or Monday, Nov. 27 or 28, he may register for the Scientific Assembly in the Secretary's Office near the Ballroom at the Statler.

Registration for Lay Executive Secretaries

Lay executive secretaries of component and constituent associations may register any time Sunday or Monday, Nov. 27 or 28, or any time *after 12 noon* Tuesday, Nov. 29, during the week of the session in the Secretary's Office near the Ballroom at the Statler.

TRANSPORTATION

Railroad or Air Travel

It is suggested that those physicians who contemplate traveling to Boston to attend the Clinical Meeting of the Association secure information concerning railroad and airplane travel directly from their local ticket agents, who are in position to give them information regarding train or plane schedules and fares. Since the meeting is being held close to the Thanksgiving holiday, when travel by all means of transportation will be heavy, reservations should be made promptly.

BOSTON HOTELS

If hotel reservations have not yet been secured by physicians other than delegates or officers of the Association who expect to attend the Boston meeting, it is suggested that such physicians fill in and send directly to Chairman, A. M. A. Housing Committee, 80 Federal St., Boston 15, Mass., the application form which may be found on advertising page 101 of this issue of The Journal. Please do *not* send applications for hotel reservations to the American Medical Association offices in Chicago. The Boston Convention Bureau is assisting the Housing Committee of the Local Committee on Arrangements.

MEETING PLACES

(See the map of Boston on advertising page 101 in this issue of The Journal.)

General Headquarters, Registration Bureau, Scientific Exhibit, Technical Exhibits, and Information Bureau: Mechanics Hall.

House of Delegates: Ballroom, Hotel Statler.

Scientific Meetings: Mechanics Hall.

Mechanics Hall is located at 111 Huntington Ave.

PUBLIC RELATIONS CONFERENCE

Dr. Dwight H. Murray, President-Elect, will keynote the American Medical Association's Eighth National Medical Public Relations Conference preceding the Boston Clinical Meeting. The Medical Public Relations Conference, which is titled "America, '56," will get under way at 10 a. m., Monday, Nov. 28, in the Ballroom Assembly of the Hotel Statler.

ENTERTAINMENT

Boston Symphony Orchestra

1955 marks the 75th anniversary of the founding of the famous Boston Symphony Orchestra. The hosts for the Boston Clinical Meeting have made arrangements for a special concert by the orchestra on Thursday, Dec. 1, at 8:30 p. m. Dr. Charles Munch will conduct works of Mozart, Brahms, and Richard Strauss. Through the courtesy of Winthrop-Stearns, Inc., complimentary tickets will be available to those desiring them at the Registration Bureau in Mechanics Hall.

Luncheon for Women Physicians

The Boston branch of the American Medical Women's Association has extended an invitation to all women physicians who will attend the Clinical Meeting to be its guests at a luncheon Nov. 30, 1955, at the Women's City Club of Boston. Those interested should communicate with Dr. Marian W. Perry, 88 Scotland Rd., Reading 3, Mass.

"ARS Medica" Collection

A unique collection of medical art by Rembrandt, Daumier, Hogarth, Toulouse-Lautrec, and other great masters depicting the practice of medicine over the centuries will be shown at the Boston meeting on the Balcony of Grand Hall in Mechanics Hall, through the courtesy of Smith, Kline and French Laboratories and the Boston Medical Library. The collection, composed of 85 famous and rare pieces of graphic art, was assembled under a grant by Smith, Kline & French Laboratories, Philadelphia, and presented to the Philadelphia Museum of Art.

POSTCONVENTION TOUR TO THE BAHAMAS

An official postconvention tour is planned immediately after the Boston meeting. A group will leave Boston for New York on Friday afternoon Dec. 2, and on Saturday noon there will be a flight to Nassau, where an interesting and varied program has been arranged. The Bahamas Medical Association is having a scientific meeting in Nassau on Wednesday, Dec. 7, for presentation of a program typical of medical practice in the Bahamas.

Tour members will return to Miami on Saturday, Dec. 10, from where departures may be arranged to home cities. Extensions of the tour or visits to other islands can be arranged.

Full information can be obtained from A. M. A.-Nassau Tour Headquarters, 35 E. Monroe St., Chicago, Ill.

LOCAL COMMITTEE ON ARRANGEMENTS

Central Committee

Frank P. Foster, General Chairman
Laurence B. Ellis, Co-Chairman
Charles S. Davidson, Program
Richard Warren, Television
Thomas A. Warthin, Entertainment and Films

New England States Representatives

Harold M. Marvin, Connecticut
Gerald C. Leary, Maine
Deering G. Smith, New Hampshire
Ellsworth L. Amidon, Vermont
Henri E. Gauthier, Rhode Island

Subcommittee on Television

Dr. Alexander Marble, Chairman
Kenneth W. Warren
C. Cavell Bailey

Subcommittee on Entertainment

Albert S. Murphy, Chairman
Victoria Cass

Subcommittee on Program

Theodore L. Badger, Chairman
John R. Graham, Co-Chairman, Medicine
Lamar Soutter, Co-Chairman, Surgery
Robert F. Bradley
Earle M. Chapman
John F. Conlin
James H. Currens
Charles S. Davidson
Eugene C. Eppinger
Frank P. Foster
Dale G. Friend
F. Thomas Gephart
David M. Greeley
William C. Moloney
Langdon Parsons
Samuel H. Proger
J. Gordon Scannell
Frederick J. Stare
Richard P. Stetson
Morris B. Strauss

Subcommittee on Motion Pictures

Norman Lenson, Chairman

HOUSE OF DELEGATES

The House of Delegates will meet at 10 a. m., Tuesday, Nov. 29, 1955, in the Ballroom of the Hotel Statler.

The Reference Committee on Credentials will meet near the entrance to the Ballroom at 8:30 a. m., Tuesday, Nov. 29, 1955. Credentials should be presented to the Reference Committee on Credentials as early as possible, so that the official roll of the House may be made up and so that the House of Delegates may organize promptly and proceed with its business. The Reference Committee on Credentials will also meet preceding each subsequent meeting of the House of Delegates.

Each delegate should present properly executed credentials signed by the president or secretary of the constituent association or by the chairman or secretary of the section he represents. Alternates presenting credentials should see that the delegates whose places they are to take have signed the alternate authorization.

Each delegate, *before* registering with the Reference Committee on Credentials, should register for the Scientific Assembly at a desk located near the Ballroom. Rooms have been provided for the use of committees of the House of Delegates. Reference committees are urged to have their meetings in these rooms and to announce the time of their meetings, so that any who are interested in referred matters may be able to appear before the committees.

Typists will be at the service of the members of the House of Delegates for preparing official reports, resolutions, and motions in the Secretary's Office, which will be in close proximity to the Ballroom.

REFERENCE COMMITTEES OF THE HOUSE OF DELEGATES

The Speaker of the House of Delegates, Dr. E. Vincent Askey, California, has appointed delegates to serve on the reference committees of the House at the Boston meeting as follows:

Amendments to the Constitution and Bylaws

J. J. Crane, *Chairman*, Section on Urology
Maurice J. Dattelbaum, New York
Karl S. J. Hohlen, Nebraska
Francis T. Holland, Florida
Stanley B. Weld, Connecticut

Board of Trustees and Secretary, Reports of

Homer M. Izumi, *Chairman*, Hawaii
Woodruff L. Crawford, Section on Pediatrics
Frank A. MacDonald, California
Kenneth C. Sawyer, Colorado
Dexter H. Witte, Wisconsin

Credentials

Raymond F. Peterson, *Chairman*, Montana
Thomas M. D'Angelo, New York
John N. Gallivan, Connecticut
R. T. Johnstone, Section on Preventive and Industrial Medicine and Public Health
Spencer A. Kirkland, Georgia

Executive Session

William F. Costello, *Chairman*, New Jersey
Frank J. Elias, Minnesota
Leopold H. Fraser, California
Howard K. Petry, Pennsylvania
Rolland J. Whitacre, Section on Anesthesiology

Hygiene, Public Health, and Industrial Health

L. Howard Schriver, *Chairman*, Ohio
Thomas J. Danaher, Connecticut
Gerald D. Dorman, New York
Paul D. Foster, California
H. Kenneth Scatliff, Illinois

Insurance and Medical Service

Lewis A. Alesen, *Chairman*, California
R. J. Azzari, New York
Lester D. Bibler, Section on General Practice
John K. Glen, Texas
H. Linton January, New Mexico

Legislation and Public Relations

Raymond L. Zech, *Chairman*, Washington
Earle M. Chapman, Massachusetts
Paul A. Davis, Ohio
John J. Masterson, New York
Elmer G. Shelley, Pennsylvania

Medical Education and Hospitals

George M. Fister, *Chairman*, Utah
Warde B. Allan, Maryland
Alfred H. Ellison, Indiana
Warren W. Furey, Illinois
William A. Hyland, Michigan

Medical Military Affairs

Charles H. Richardson Sr., *Chairman*, Georgia
Otis O. Benson Jr., United States Air Force
William C. Chaney, Tennessee
Louis W. Jones, Pennsylvania
Russel V. Lee, Section on Military Medicine

Miscellaneous Business

Frank H. Krusen, *Chairman*, Section on Physical Medicine
Reuben B. Chrisman Jr., Florida
Frank J. Holroyd, West Virginia
William M. Skipp, Ohio
James H. Wooten Jr., Texas

Reports of Officers

Wesley W. Hall, *Chairman*, Nevada
William L. Estes Jr., Pennsylvania
Thurman B. Givan, New York
Robert L. Novy, Michigan
Donovan F. Ward, Iowa

Rules and Order of Business

B. O. Edwards, *Chairman*, North Carolina
C. Byron Blaisdell, New Jersey
George D. Johnson, South Carolina
Ezra A. Wolff, New York
Hoyt B. Woolley, Idaho

Sections and Section Work

Gilson Colby Engel, *Chairman*, Pennsylvania
Howard M. Bubert, Maryland
John S. DeTar, Michigan
Philip S. Foisie, Massachusetts
B. E. Montgomery, Illinois

Tellers

Eustace A. Allen, *Chairman*, Georgia
Charles J. Ashworth, Rhode Island
Orwood J. Campbell, Minnesota
Frank L. Feierabend, Missouri
John F. Lucas, Mississippi

Sergeants-at-Arms

William F. Brennan, *Chairman*, Pennsylvania
David W. Gaiser, Washington
C. Paul White, Illinois

MEMBERS OF THE HOUSE OF DELEGATES

A Roster of the Legislative Body of the American Medical Association

Following is a list of the members of the House of Delegates.

DELEGATES FROM CONSTITUENT ASSOCIATIONS

ALABAMA
B. W. McNease, Fayette
E. Bryce Robinson Jr., Fairfield

ARIZONA
Jesse D. Hamer, Phoenix

ARKANSAS
William R. Brooksher, Fort Smith
Rufus B. Robins, Camden

CALIFORNIA
Lewis A. Alesen, Los Angeles
E. Vincent Askey, Los Angeles
Donald Cass, Los Angeles
Paul D. Foster, Los Angeles
Leopold H. Fraser, Richmond
John Winston Green, Vallejo
Eugene F. Hoffman, Los Angeles
R. Stanley Kneeshaw, San Jose
J. Lafe Ludwig, Los Angeles
Frank A. MacDonald, Sacramento
Sam J. McClendon, San Diego
Robertson Ward, San Francisco
Dwight L. Wilbur, San Francisco

COLORADO
Kenneth C. Sawyer, Denver
George A. Unfug, Pueblo

CONNECTICUT
Thomas J. Danaher, Torrington
John N. Gallivan, East Hartford
Stanley B. Weld, Hartford

DELAWARE
H. Thomas McGuire, New Castle

DISTRICT OF COLUMBIA
Raymond T. Holden, Washington
Hugh H. Hussey Jr., Washington

FLORIDA
Reuben B. Chrisman Jr., Miami
Francis T. Holland, Tallahassee
Louis M. Orr, Orlando

GEORGIA
Eustace A. Allen, Atlanta
Spencer A. Kirkland, Atlanta
Charles H. Richardson, Macon

IDAHO
Hoyt B. Woolley, Idaho Falls

ILLINOIS
Walter C. Bornemeier, Chicago
Everett P. Coleman, Canton
Harlan English, Danville
Warren W. Furey, Chicago
Percy E. Hopkins, Chicago
B. E. Montgomery, Harrisburg
J. Mather Pfeiffenberger, Alton
Charles H. Phifer, Chicago
H. Kenneth Scatliff, Chicago
C. Paul Write, Kewanee

INDIANA
Alfred H. Ellison, South Bend
Eli S. Jones, Hammond
Cleon A. Nafe, Indianapolis
Wendell C. Stover, Boonville

IOWA
Francis C. Coleman, Des Moines
Robert N. Larimer, Sioux City
Donovan F. Ward, Dubuque

KANSAS
George F. Gsell, Wichita
Laurence S. Nelson Sr., Salina

KENTUCKY
Clark Bailey, Harlan
Bruce Underwood, Louisville

LOUISIANA
James Q. Graves, Monroe
Philip H. Jones, New Orleans

MAINE
Martyn A. Vickers, Bangor

MARYLAND
Warde B. Allan, Baltimore
Howard M. Bubert, Baltimore

MASSACHUSETTS
Earle M. Chapman, Boston
Lawrence R. Dame, Greenfield
Philip S. Foisie, Boston
Charles G. Hayden, Boston
Harold R. Kurth, Lawrence
Norman A. Welch, Boston

MICHIGAN
Wyman D. Barrett, Detroit
John S. DeTar, Milan
Willis H. Huron, Iron Mountain
William A. Hyland, Grand Rapids
Ralph A. Johnson, Detroit
Robert L. Novy, Detroit

MINNESOTA
J. Arnold Bargen, Rochester
Orwood J. Campbell, Minneapolis
George A. Earl, St. Paul
Frank J. Elias, Duluth

MISSISSIPPI
John P. Culpepper Jr., Hattiesburg
John F. Lucas, Greenwood

MISSOURI
Arthur S. Bristow, Princeton
Frank L. Feierabend, Kansas City
Durward G. Hall, Springfield
Joseph C. Peden Sr., St. Louis

MONTANA
Raymond F. Peterson, Butte

NEBRASKA
Karl S. J. Hohlen, Lincoln
Joseph D. McCarthy, Omaha

NEVADA
Wesley W. Hall, Reno

NEW HAMPSHIRE
Deering G. Smith, Nashua

NEW JERSEY
C. Byron Blaisdell, Asbury Park
William F. Costello, Dover
Aldrich C. Crowe, Ocean City
J. Wallace Hurff, Newark
L. Samuel Sica, Trenton
Elmer P. Weigel, Plainfield

NEW MEXICO
H. Linton January, Albuquerque

NEW YORK
A. H. Aaron, Buffalo
Walter P. Anderton, New York
R. J. Azzari, New York
Herbert H. Bauckus, Buffalo
Thomas M. D'Angelo, Jackson Heights
Maurice J. Dattelbaum, Brooklyn
Peter J. DiNatale, Batavia
Gerald D. Dorman, New York
Andrew A. Eggston, Mt. Vernon
Edward P. Flood, Bronx
Thurman B. Givan, Brooklyn
J. Stanley Kenney, New York
Charles H. Loughran, Brooklyn
John J. Masterson, Brooklyn
Peter M. Murray, New York
Carlton E. Wertz, Buffalo
Floyd S. Winslow, Rochester
Ezra A. Wolff, Forest Hills

NORTH CAROLINA
B. O. Edwards, Asheville
Millard D. Hill, Raleigh
Charles F. Strosnider, Goldsboro

NORTH DAKOTA
Willard A. Wright, Williston

OHIO
Arthur A. Brindley, Toledo
Paul A. Davis, Akron
Carl A. Lincke, Carrollton
L. Howard Schriver, Cincinnati
Clifford C. Sherburne, Columbus
William M. Skipp, Youngstown
George A. Woodhouse, Pleasant Hill
Herbert B. Wright, Cleveland

OKLAHOMA
John F. Burton, Oklahoma City
Elbert H. Shuller, McAlester

OREGON
Raymond M. McKeown, Coos Bay
Archie O. Pitman, Hillsboro

PENNSYLVANIA
James Z. Appel, Lancaster
William F. Brennan, Pittsburgh
Gilson Colby Engel, Philadelphia
William L. Estes Jr., Bethlehem
Harold B. Gardner, Harrisburg
Louis W. Jones, Wilkes-Barre
George S. Klump, Williamsport
Thomas W. McCreary, Rochester
Howard K. Petry, Harrisburg
Charles L. Shafer, Kingston
Elmer G. Shelley, North East

RHODE ISLAND
Charles J. Ashworth, Providence

SOUTH CAROLINA
George Dean Johnson, Spartanburg
William Weston Jr., Columbia

SOUTH DAKOTA
Arthur A. Lampert, Rapid City

TENNESSEE
William C. Chaney, Memphis
Charles M. Hamilton, Nashville
Charles C. Smeltzer, Knoxville

TEXAS
Joseph B. Copeland, San Antonio
John K. Glen, Houston
Robert B. Homan Jr., El Paso
Milford O. Rouse, Dallas
Arthur C. Scott, Temple
Truman C. Terrell, Fort Worth
James H. Wooten Jr., Columbus

UTAH
George M. Fister, Ogden

VERMONT
James P. Hammond, Bennington

VIRGINIA
Vincent W. Archer, Charlottesville
J. Morrison Hutcheson, Richmond

WASHINGTON
R. A. Benson, Bremerton
David W. Gaiser, Spokane
Raymond L. Zech, Seattle

WEST VIRGINIA
Frank J. Holroyd, Princeton
Walter E. Vest, Huntington

WISCONSIN
Stephen E. Gavin, Fond du Lac
Joseph C. Griffith, Milwaukee
William D. Stovall, Madison
Dexter H. Witte, Milwaukee

WYOMING
W. Andrew Bunten, Cheyenne

ALASKA
Milo H. Fritz, Anchorage

HAWAII
Homer M. Izumi, Honolulu

ISTHMIAN CANAL ZONE
Lewis B. Bates, East Weymouth, Mass.

PUERTO RICO
F. Sánchez-Castaño, Vega Baja

DELEGATES FROM THE SECTIONS AND GOVERNMENT SERVICES

ANESTHESIOLOGY
Rolland J. Whitacre, East Cleveland, Ohio

DERMATOLOGY
Robert R. Kierland, Rochester, Minn.

DISEASES OF THE CHEST
Hollis E. Johnson, Nashville, Tenn.

EXPERIMENTAL MEDICINE AND THERAPEUTICS
Edgar V. Allen, Rochester, Minn.

GASTROENTEROLOGY AND PROCTOLOGY
Louis A. Buie, Rochester, Minn.

GENERAL PRACTICE
Lester D. Bibler, Indianapolis

INTERNAL MEDICINE
Charles T. Stone Sr., Galveston, Texas

LARYNGOLOGY, OTOLOGY AND RHINOLOGY
Gordon F. Harkness, Davenport, Iowa

MILITARY MEDICINE
Russel V. Lee, Palo Alto, Calif.

NERVOUS AND MENTAL DISEASES
Hans H. Reese, Madison, Wis.

OBSTETRICS AND GYNECOLOGY
Ralph E. Campbell, Madison, Wis.

OPHTHALMOLOGY
William L. Benedict, Rochester, Minn.

ORTHOPEDIC SURGERY
H. Relton McCarroll, St. Louis

PATHOLOGY AND PHYSIOLOGY
Lall G. Montgomery, Muncie, Ind.

PEDIATRICS
W. L. Crawford, Rockford, Ill.

PHYSICAL MEDICINE
Frank H. Krusen, Rochester, Minn.

PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH
R. T. Johnstone, Los Angeles

RADIOLOGY
Byrl R. Kirklin, Rochester, Minn.

SURGERY, GENERAL AND ABDOMINAL
Grover C. Penberthy, Detroit

UROLOGY
J. J. Crane, Los Angeles

UNITED STATES AIR FORCE
Otis O. Benson Jr.

UNITED STATES ARMY
James P. Cooney

UNITED STATES NAVY
B. E. Bradley

PUBLIC HEALTH SERVICE
W. Palmer Dearing

VETERANS ADMINISTRATION
Roy A. Wolford

There will be present also two students representing the Student American Medical Association.

SCIENTIFIC PROGRAM

MECHANICS' BUILDING

The Council on Scientific Assembly, in presenting the following program of scientific lectures, color television, motion pictures, and scientific exhibits, wishes to extend its appreciation to the Local Committee on Arrangements in Boston for its contribution of time and energy. Practically the whole program is the result of the effort of the General Chairman, together with the Program Committee, over many months of activity.

SCIENTIFIC LECTURES

OPENING GENERAL ASSEMBLY: GRAND HALL

Tuesday morning, Nov. 29

Chairman: Frank P. Foster, Boston.

10:30 **Welcome Addresses:**
Elliott P. Joslin, Boston.
Elmer Hess, Erie, Pa.

11:00 **The Art of Medicine.** C. Sidney Burwell, Boston.

11:45 **Trends in Medical Research.**
James A. Shannon, Bethesda, Md.

Tuesday afternoon, Nov. 29

Chairman: Earle M. Chapman, Boston.
Co-Chairman: Deering G. Smith, Boston.

2:00 **Clinical Pathological Cases.**

1. Benjamin Castleman, Boston, and Cecil J. Watson, Minneapolis.
2. Ralph E. Miller, Hanover, N. H., and Lester R. Dragstedt, Chicago.

3:30 **Panel on Antimicrobial Therapy.**
Chester S. Keefer, Boston, Moderator.

PAUL REVERE HALL

Tuesday afternoon, Nov. 29

Chairman: J. Gordon Scannell, Boston.
Co-Chairman: Richard Warren, Boston.

2:00 **Panel on Anemia.**
William B. Castle, Boston, Moderator.

3:00 **Common Emergencies in the Care of the Critically Ill: The Airway, Blood Volume, and Renal Function.**
Francis C. Moore, Boston.

3:30 **Nitrous Oxide-Oxygen-Curare Analgesia for Major Surgery in the Poor-Risk Patient.**
Morris L. Heller and T. Richard Watson, Hanover, N. H.

4:00 **Nonunion of Bone.** Edwin F. Cave, Boston.

4:30 **Management of the Frozen Shoulder.**
G. Edmund Haggart, Robert J. Dignam, and Thomas H. Sullivan, Boston.

The Treatment of Checkrein Shoulder by Manipulation and Cortisone. T. B. Quigley, Boston.

TALBOT HALL

Tuesday afternoon, Nov. 29

Chairman: David M. Greeley, Boston.
Co-Chairman: Thomas A. Warthin, Boston.

2:00 **Panel on Adolescent Medicine.**
Charles A. Janeway, Boston, Moderator.

3:00 **The Significance of a Fat-Splitting Enzyme in the Urine for the Diagnosis of Pancreatic Disease.**
Martin M. Nothmann, Boston.

Present-Day Concepts of Anacidity.
Howard M. Spiro, New Haven, Conn.

3:30 **The Clinical Use of the Urinary Uropepsin Excretion in Gastrointestinal and Endocrine Diseases.**
Seymour J. Gray, Colin G. Ramsey, Vincent A. DeLuca Jr., and Lewis J. Krakauer, Boston, and Robert W. Reifenstein, Syracuse, N. Y.

4:00 **Hiatus Hernia, Esophago-Gastric Hemorrhage, Marginal Esophageal Ulcer, and Mallory-Weiss Syndrome.**
Felix G. Fleischner, Boston.

4:30 **Results of Subtotal Gastric Resection (Billroth II) for Duodenal Ulcer Disease: (1) The Influence of Preoperative Acidity upon Postoperative Acidity in Relation to the Extent of Resection and (2) Relation of Postoperative Sequelae to Extent of Resection.**
James L. A. Roth, I. Becker, S. Vine, and H. L. Bockus, Philadelphia.

GRAND HALL

Wednesday morning, Nov. 30

Chairman: Lamar Soutter, Boston.
Co-Chairman: Theodore L. Badger, Boston.

9:30 **Control of Hepatitis.** Richard B. Capps, Chicago.

10:00 **Responsibility of the Family Doctor in the Treatment of Tuberculosis.** J. Burns Amberson Jr., New York.

10:30 **The Acute Abdomen.** I. S. Ravdin, Philadelphia.

11:00 **Panel on Psychotherapy in General Practice.**
Claude E. Forkner, New York, Moderator.

PAUL REVERE HALL

Wednesday morning, Nov. 30

Chairman: Maurice B. Strauss, Boston.
Co-Chairman: Alexander Marble, Boston.

9:00 **Pheochromocytoma—A Clinicopathological Analysis of Thirty-Eight Cases.** Meyer M. Melicow, New York.

9:30 **Persistent Hyperthyroidism with Normal Protein-Bound Iodine While on Antithyroid Drugs.**
Earle M. Chapman and Farahe Maloof, Boston.

10:00 **Diabetes of Thirty-Five Years' Duration.**
Paul L. Barclay and Howard F. Root, Boston.

10:30 **On Death by Drowning.**
Christopher C. Shaw, Philadelphia.

11:00 **The Pathogenesis of Acute Glomerulonephritis and Lipid Nephrosis: Demonstration of Glomerular-Localizing Globulins.**
Robert C. Mellors and Louis G. Ortega, New York.

11:30 **Incidence of Asymptomatic Infections of the Urinary Tract in an Outpatient Population.**
Edward H. Kass and Egon Riss, Boston.

12:00 **Environmental Support in Long-Term Illness.**
Robert P. Smith, Boston.

TALBOT HALL

Wednesday morning, Nov. 30

Chairman: JOHN R. GRAHAM, Boston.

Co-Chairman: RICHARD P. STETSON, Boston.

9:00 **Practical Aspects of the Preanesthetic Management of Children in a Community Hospital.**
PETER G. LEHNDORFF, A. D. DELISLE, and N. H. STEWART, Fitchburg, Mass.

Another Look at Acne Vulgaris in Adolescence.
WILLIAM R. HILL, FELIX P. HEALD, ROBERT P. MASLAND JR., and J. ROSWELL GALLAGHER, Boston.

9:30 **The Crying Baby.** DAVID McL. GREELEY, Boston.

10:00 **Accidental Poisoning in Children.**
HAROLD JACOBZINER, New York.

10:30 **Blood Replacement in Thoracic Surgery for Children.**
ROBERT M. SMITH and ROBERT E. GROSS, Boston.

11:00 **Hypothyroidism in Adolescence.**
FELIX P. HEALD, ALBERT E. RENOLD, and J. ROSWELL GALLAGHER, Boston.

11:30 **Management of Behavior Disorders in Children.**
HARRY BAKWIN, New York.

12:00 ***The Clinical Management of Phenylketonuria.***
DAVID YI-YUNG HSIA, WALTER TROLL, and W. EUGENE KNOX, Boston.

GRAND HALL

Wednesday afternoon, Nov. 30

Chairman: F. THOMAS GEPHART, Boston.

Co-Chairman: HENRI E. GAUTHIER, Boston.

2:00 **Poliomyelitis and Other Viruses.**
THOMAS H. WELLER, Boston.

2:30 **X-Ray Presentation.** MERRILL C. SOSMAN, Boston.

3:30 **Panel on Evaluation and Management of the Surgical Risk.**
ARTHUR W. ALLEN, Boston, Moderator.

PAUL REVERE HALL

Wednesday afternoon, Nov. 30

Chairman: LAURENCE B. ELLIS, Boston.

Co-Chairman: FREDRICK J. STARE, Boston.

2:00 **A Simple Clinical Test for Detecting the Altered Cardiodynamics of Ventricular Failure of Valvular Stenosis.**
JOHN H. KNOWLES and RICHARD GORLIN, Portsmouth, Va.

2:30 **The Influence of Heart Disease on Surgical Risk.**
J. B. DANA and ROBERT L. OHLER, Togus, Maine.

Age, Serum Lipids, and Coronary Atherosclerosis.
DAVID ADLERSBERG, LOUIS E. SCHAEFER, ARTHUR G. STEINBERG, and CHUN-I WANG, New York.

3:00 **Isolated Aortic Stenosis: Evaluation for Surgical Treatment, Choice of Operation, and Results.**
GEORGE B. STARKEY and WALTER H. ABELMANN, Boston.

3:30 **The Varied Manifestations of Dissecting Aneurysm of the Aorta.** SAMUEL BAER, Philadelphia.

4:00 **The Pathogenesis of Acute Peripheral Arterial Occlusion: A Basis for Clinical Management.**
STANFORD WESSLER and MARVIN GILBERT, Boston.

4:30 **Remittent Necrotizing Acrocyanosis.**
EDWARD A. EDWARDS, Boston.

TALBOT HALL

Wednesday afternoon, Nov. 30

Chairman: LANGDON PARSONS, Boston.

Co-Chairman: EUGENE C. EPPINGER, Boston.

2:00 **Renal Function Studies Throughout Pregnancy in the Normal Woman.**
KERMIT E. KRANTZ and ETHAN A. H. SIMS, Burlington, Vt.

2:30 **Coagulation Defects in Severe Intrapartum and Postpartum Hemorrhage.**
DUNCAN E. REID, CHARLES C. ROBY, and ALBERT E. WEINER, Boston.

3:00 **The Repeat Cesarean—A Review of 1,000 Cases.**
ROY J. HEFFERNAN and WILLIAM A. LYNCH, Boston.

3:30 **Saphenous Vein Stripping for Varicose Veins During Pregnancy.**
RODGER E. WEISMANN and EDWARD W. JENKINS, Hanover, N. H.

4:00 **The Management of Hypertension Associated with Pregnancy.**
JAMES H. CURRENS and DUNCAN E. REID, Boston.

4:30 **The Menopause: A Review of the Problem.**
JOSEPH ROGERS, Boston.

GRAND HALL

Thursday morning, Dec. 1

Chairman: EUGENE C. EPPINGER, Boston.

Co-Chairman: HAROLD M. MARVIN, Boston.

9:30 **Postmenopausal Bleeding.** JOE V. MEIGS, Boston.

10:00 **Reversible Uremic States.**
FRANKLIN H. EPSTEIN, New Haven, Conn.

10:30 **Epidemiology of Cardiovascular Disease.**
PAUL D. WHITE, Boston.

11:00 **Panel on Drugs, Radiation, and Surgery in the Management of Cancer.**
J. ENGLEBERT DUNPHY, Boston, Moderator.

PAUL REVERE HALL

Thursday morning, Dec. 1

Chairman: THEODORE L. BADGER, Boston.

Co-Chairman: LAMAR SOUTTER, Boston.

9:00 **Treatment of Spontaneous Pneumothorax.**
ARMAND A. LEFEMINE, EDWARD T. O'HARA, and JOSEPH P. LYNCH, Boston.

9:30 **Lung Function Tests: Their Value in Medical Diagnosis and Treatment.**
DAVID W. CUGELL, WALTER H. ABELMANN, EDWARD A. GAENSLER, and THEODORE L. BADGER, Boston.

10:00 **Chronic Obstructive Pulmonary Emphysema.**
FRANCIS C. LOWELL, WILLIAM FRANKLIN, ALAN L. MICHELSON, and IRVING W. SCHILLER, Boston.

10:30 **Lipid Pneumonia Simulating Lung Cancer.**
JOHN L. POOL and LOTON H. RASMUSSEN, New York.

The Treatment of Acute Respiratory Insufficiency.
EUGENE D. ROBIN, JOHN M. TYLER, EUGENE C. EPPINGER, and DON J. WEEKES, Boston.

11:00 **The Importance of Mitral Stenosis in Patients with Symptoms of Chronic Pulmonary Disease.**
GORDON S. MYERS, EDWARD F. BLAND, ALLAN L. FRIEDLICH, and J. GORDON SCANNELL, Boston.

11:30 **Empyema in Infants and Children.**
DONALD B. MILLER and R. JAMES MCKAY JR., Burlington, Vt.

Empyema Thoracis in the Antibiotic Era.
JOSEPH P. LYNCH and GERARD DESFORGES, Boston.

12:00 **Postgraduate Medical Education in the Nonuniversity Hospital.** JOHN C. LEONARD, Hartford, Conn.

TALBOT HALL

Thursday morning, Dec. 1

Chairman: ROBERT F. BRADLEY, Boston.
Co-Chairman: WILLIAM C. MOLONEY, Boston.

9:00 **Cerebral Arteriosclerosis.**
NAOMI RASKIN, Dorchester, Mass.

Senile Degenerations of the Brain and Their Relations to Psychoses and Diseases.
GEORGE STRASSMANN and MYER ASEKOFF, Waltham, Mass.

9:30 **The Administration of Anticoagulant Drugs in the Prevention and Treatment of Certain Types of Strokes.**
C. H. MILLIKAN, R. G. SIEKERT, J. P. WHISNANT, and R. M. SHICK, Rochester, Minn.

10:00 **Prognostic Studies in Cerebral Palsy.**
ERIC DENHOFF, MAURICE L. SILVER, and RAYMOND H. HOLDEN, Providence, R. I.

10:30 **The Clinical Significance of the Syndrome of Hereditary Light Sensitivity.**
C. WESLEY WATSON, SHERWOOD DAVIDSON, and JOHN F. SULLIVAN, Boston.

11:00 **Clinical Observations of Manic-Depressive Disease.**
WALTER E. CASSIDY, NORRIS B. FLANAGAN, MARIE SPELLMAN, and MANDEL E. COHEN, Boston.

A Report of Five Deaths in Electrotherapy with Necropsy Findings in Four of the Cases.
SAUNDERS P. ALEXANDER, LAWRENCE H. GAHAGAN, and WILLIAM HALL LEWIS JR., New York.

11:30 **Five-Year Follow-Up of Patients Subjected to Three Different Lobotomy Procedures.**
NORMAN PAUL, EDWARD FITZGERALD, and MILTON GREENBLATT, Boston.

12:00 **Occupational Stress and Emotional Illness.**
JACKSON A. SMITH, Houston, Texas.

Compliancy Factor in Obesity and Skinniness.
ADELAIDE M. JOHNSON, S. H. FRAZIER, M. E. GIFFEN, and M. H. FAUBION, Rochester, Minn.

GRAND HALL

Thursday afternoon, Dec. 1

Chairman: SAMUEL H. PROGER, Boston.
Co-Chairman: GERALD C. LEARY, Boston.

2:00 **Clinical Pathological Cases.**
1. SHIELDS WARREN, Boston, and GEORGE W. WRIGHT, Cleveland.
2. ARTHUR T. HERTIG and JOE V. MEIGS, Boston.

3:30 **Panel on Impact of Prolonged Specialty Training upon General Practice.**
EDWIN L. CROSBY JR., Chicago, Moderator.

PAUL REVERE HALL

Thursday afternoon, Dec. 1

Chairman: RICHARD WARREN, Boston.
Co-Chairman: LANGDON PARSONS, Boston.

2:00 **Panel on Industrial Medicine.**
HARRIET L. HARDY, Boston, Moderator.

3:00 **Open Wounds of the Hand.** J. EDWARD FLYNN, Boston.

3:30 **Skin Grafts for Chronic Open Wounds of the Lower Extremity.**
JOSEPH E. MURRAY and BRADFORD CANNON, Boston.

4:00 **The Surgical Treatment of Abdominal Aortic Aneurysm.**
DAVID P. BOYD, Boston.

4:30 **Evaluation of Induced Hypotension in Craniotomy.**
VALENTINO D. B. MAZZIA, BRONSON S. RAY, and JOSEPH F. ARTUSIO JR., New York.

TALBOT HALL

Thursday afternoon, Dec. 1

Chairman: DALE G. FRIEND, Boston.
Co-Chairman: F. THOMAS GEPHART, Boston.

2:00 **Panel on Seizures.**
JOSEPH M. FOLEY, Boston, Moderator.

3:00 **Serious Complications Due to Trauma of the Occiput.**
ROBERT G. FISHER and JUNG K. KIM, Hanover, N. H.

3:30 **Evaluation of Thymectomy in Myasthenia Gravis.**
HENRY R. VIETS and ROBERT S. SCHWAB, Boston.

4:00 **The Care of the Bladder in Neurological Disorders.**
HERBERT S. TALBOT, West Roxbury, Mass.

4:30 **Sound Projection Testing of Emotionally Ill United States Naval Personnel.**
H. A. WILMER, D. C. GAEDE, and D. BRIGGS, Oakland, Calif.

GRAND HALL

Friday morning, Dec. 2

Chairman: RICHARD P. STETSON, Boston.
Co-Chairman: ELLSWORTH L. AMIDON, Boston.

9:30 **Management of Acute Cerebrovascular Disease.**
RAYMOND D. ADAMS, Boston.

10:00 **Cause and Prevention of Developmental Defects.**
THEODORE H. INGALLS, Boston.

10:30 **Atoms for Peace.** WILLIAM H. SWEET, Boston.

11:00 **Panel on the Cortisones in the Treatment of Infections, Arthritis, and Malignant and Degenerative Diseases.**
RANDALL G. SPRAGUE, Rochester, Minn., Moderator.

PAUL REVERE HALL

Friday morning, Dec. 2

Chairman: FREDRICK J. STARE, Boston.
Co-Chairman: CHARLES S. DAVIDSON, Boston.

9:00 **Prediction of the Response to Radioiodine Treatment for Hyperthyroidism.**
BELTON A. BURROWS, MARVIN L. MITCHELL, ELISABETH A. DELL, and DOROTHY A. GRAHAM, Boston, and JOSEPH F. ROSS, Los Angeles.

9:30 **The Clinical Use and Anticoagulant Properties of Phenindione.**
HERBERT S. SISE, DIONYSIOS ADAMIS, and DELBERT M. KIMBALL, Boston.

10:00 **The Management of Idiopathic Thrombocytopenic Purpura.**
MILTON S. SACKS and ALICE M. BAND, Baltimore, Md.

10:30 **Hepatic Coma.** SHEILA SHERLOCK, London, England.

11:00 **The Treatment with Sodium Phytate of Hypercalcemia and Hypercalcuria in Sarcoid, Hypervitaminosis D, and Idiopathic Hypercalcuria.**
PHILIP H. HENNEMAN, EVELYN L. CARROLL, and FULLER ALBRIGHT, Boston.

11:30 **Hypersensitivity as a Mechanism in Vasculitis.**
ROBERT P. MCCOMBS, JAMES F. PATTERSON, and H. EDWARD MACMAHON, Boston.

12:00 **Physical and Physiological Clues for Diagnosing Eczema.**
WALTER C. LOBITZ JR. and RICHARD L. DOBSON, Hanover, N. H.

TALBOT HALL

Friday morning, Dec. 2

Chairman: WILLIAM C. MOLONEY, Boston.
Co-Chairman: MAURICE D. STRAUSS, Boston.

9:00 **The Interpretation of the Vaginal Smear in the Diagnosis of Cervical Cancer: Sensitivity Versus Specificity.**
JOSEPH E. PORTER, Portland, Maine.

9:30 **New Laboratory Procedures Which Are Useful for the Diagnosis of Cancer of the Prostate and Cancer of the Cervix.** FREDDY HOMBURGER and W. H. FISHMAN, Boston.

10:00 **Mammary Cancer: Selection of Hormone Dependent Tumors Using Urine Estrogen and Calcium Studies.**
ANDREW G. JESSIMAN, Boston.

10:30 **Prolonged Remissions of Advanced Mammary Cancer Following Cortisone Therapy.** H. M. LEMON, Boston.

11:00 **Surgical Management of Pulmonary Metastases.**
JOHN W. STRIEDER, Brookline, Mass.

11:30 **Fifty Lung Cancer Five-Year Survivors.**
RICHARD H. OVERHOLT, Boston.

12:00 **Cancer of the Colon and Rectum: A Statistical and End-Result Study.**
NEIL W. SWINTON and RUSSELL L. COUNTS, Boston.

COLOR TELEVISION

TELEVISION HALL

The following program is presented in cooperation with Smith, Kline & French Laboratories, Philadelphia, under the chairmanship of ALEXANDER MARBLE, Boston. The program will originate at the New England Deaconess Hospital, and will be viewed on screens in the Television Room, second floor, Mechanics' Building.

Tuesday afternoon, Nov. 29

2:00 **Diagnostic Evaluation of the Patient with Bleeding Disease.**
MARIO STEFANINI and ASSOCIATES, St. Elizabeth's Hospital, Boston.

2:20 **Hemorrhage and Thrombosis: Two Sides of a Coin.**
BENJAMIN ALEXANDER and STANFORD WESSLER, Beth Israel Hospital, Boston.

2:40 **The Management of Rheumatoid Arthritis.**
THEODORE B. BAYLES, Robert Breck Brigham Hospital, Boston.

3:00 **Treatment of Gout.**
ELMER C. BARTELS, Lahey Clinic, Boston.

3:20 **Clinic on Poliomyelitis.**
CHARLES A. JANEWAY, R. CANNON ELEY, WILLIAM T. GREEN, DAVID S. GRICE, SIDNEY KIBRICK, and BENJAMIN G. FERRIS JR., Children's Medical Center, Boston.

Wednesday morning, Nov. 30

9:00 **Partial Gastrectomy for Peptic Ulcer.**
SAMUEL F. MARSHALL, Lahey Clinic, Boston.

10:15 **Amputation for Diabetic Gangrene.**
LELAND S. MCKITTRICK, New England Deaconess Hospital and Massachusetts General Hospital, Boston.

Wednesday afternoon, Nov. 30

2:00 **Ileostomy Clinic.**
RICHARD WARREN and FRANCIS D. MOORE, Peter Bent Brigham Hospital, Boston.

2:20 **Treatment of Diabetic Coma.**
HOWARD F. ROOT, ROBERT F. BRADLEY, and LEO P. KRALL, Joslin Clinic and New England Deaconess Hospital, Boston.

2:40 **Medical Management of Kidney Stones.**
PHILIP H. HENNEMAN, Massachusetts General Hospital, Boston.

3:00 **Treatment of Cardiac Arrest in Stokes-Adams Disease with External Electric Stimulation, i. e., "The Pacemaker."**
PAUL M. ZOLL, Beth Israel Hospital, Boston.

3:20 **Adrenal Syndromes: Recognition and Treatment.**
GEORGE W. THORN, ALBERT E. RENOLD, and ASSOCIATES, Peter Bent Brigham Hospital, Boston.

Thursday morning, Dec. 1

9:00 **Pulmonary Resection.**
RICHARD H. OVERHOLT, New England Deaconess Hospital, Boston.

10:15 **Cholecystectomy and Choledochostomy.**
HERBERT D. ADAMS, Lahey Clinic, Boston.

11:15 **Symposium on Management of Anesthetic Emergencies.**
URBAN H. EVERSOLE and ASSOCIATES, Lahey Clinic, and LEO V. HAND and ASSOCIATES, New England Deaconess Hospital, Boston.

Thursday afternoon, Dec. 1

2:00 **Drug Treatment of Hypertension.**
ROBERT W. WILKINS, Massachusetts Memorial Hospitals, Boston.

2:20 **Diagnosis and Treatment of Common Skin Diseases.**
BERNARD APPEL, Boston City Hospital, Boston.

2:40 **Gastric Ulcer: Diagnosis and Treatment.**
MERRILL C. SOSMAN and SEYMOUR J. GRAY, Peter Bent Brigham Hospital, and SAMUEL F. MARSHALL, Lahey Clinic, Boston.

3:00 **Medical Care and Rehabilitation of the Aged and Chronically Ill.**
FREDDY HOMBURGER and CHARLES D. BONNER, Tufts College Medical School and Holy Ghost Hospital, Boston.

3:30 **Treatment of Psychiatric Patients in a General Hospital with Demonstration of Electric Shock Treatment and Presentation of a Lobotomy Case.**

ROBERT E. FLEMING and OSCAR J. RAEDER, New England Deaconess Hospital, and WALTER I. TUCKER, Lahey Clinic, Boston.

Friday morning, Dec. 2

9:00 **Abdominoperineal Resection for Carcinoma of the Rectum.** RICHARD B. CATTELL, Lahey Clinic, Boston.

10:15 **Carcinoma of the Stomach.**

RICHARD H. SWEET, New England Deaconess Hospital and Massachusetts General Hospital, Boston.

MOTION PICTURES

PAUL REVERE ANNEX

Motion pictures will be shown daily from Tuesday at 10:30 a. m. continuing through Friday noon in the Paul Revere Annex of Mechanics' Building. There will also be a Special Film Program, Wednesday evening in the Georgian Room, Hotel Statler, at 8:00 p. m.

Tuesday morning, Nov. 29

Radioisotopes: Their Application to Humans As Tracer Studies and for Therapeutic Use.

U. S. ATOMIC ENERGY COMMISSION, Washington, D. C.

This film gives a comprehensive review of the application of radioisotopes directly to the patient and shows the use of radioactive iodine, sodium, iron, calcium, lanthanum, strontium, cobalt, phosphorus, gold and the neutron capture therapy involving boron for treatment of brain tumors. Sound, 26 minutes.

Gout and Gouty Arthritis.

JOHN H. TALBOTT, Buffalo, and ALEXANDER B. GUTMAN, New York.

This film demonstrates current knowledge on the history, etiology, and diagnosis and treatment of gout and gouty arthritis, with particular reference to the uricosuric agent probenecid. Sound, 18 minutes.

Diagnosis and Office Management of the Arthritides.

WILLIAM B. RAWLS, New York.

This film shows by the split frame technique both rheumatoid arthritis and osteoarthritis at the same time. Differential diagnostic points are discussed and treatment by methods including cortisone, intra-articular injections of hydrocortisone, Butazolidin, gold therapy, and exercises are shown. Sound, 28 minutes.

Amyotrophic Lateral Sclerosis in the Mariana Islands.

LEONARD T. KURLAND, Bethesda, Md., and DONALD W. MULDER, Rochester, Minn.

This film demonstrates the clinical and pathological features in several patients and reveals that the amyotrophic lateral sclerosis observed has a high familial incidence and yet is a classical form of the disease. Progressive muscular atrophy and progressive bulbar palsy, as clinical components of amyotrophic lateral sclerosis, are illustrated. Electromyographic records are demonstrated. The absence of any effect of the disease on pregnancy and the failure of pregnancy to influence the disease are also demonstrated. Sound, 22 minutes.

Orbital Decompression in Malignant Exophthalmos.

JOSEPH DORSEY, Boston.

This film demonstrates the clinical manifestations and surgical treatment of orbital decompression in malignant exophthalmos.

Tuesday afternoon, Nov. 29

Ocular Bacteriology: Its Application to Clinical Practice.

JAMES H. ALLEN, New Orleans.

This film shows a panel of six ophthalmologists participating in a panel discussion of bacteriology of the eye. It covers bacteriological examination of the lids and lacrimal apparatus, conjunctival lesions, intraocular inflammations and infections, orbital infections, and examination of ocular allergies. Sound, 40 minutes.

Recording Oximeters and Their Application.

JOHN F. PERKINS JR. and WILLIAM ADAMS, Chicago.

This motion picture briefly outlines principles of operation of ear oximeters, advantages of recording type oximeters over galvanometer types, uses of oximeters in teaching physiology of respiration, in pulmonary function studies, in thoracic surgery, and in postoperative oxygen therapy. Sound, 17 minutes.

Fractures About the Wrist and Hand.

VETERANS ADMINISTRATION, Washington, D. C.

This film discusses the functional anatomy of the wrist and hand, particularly as it relates to fractures in that area. The mechanisms of typical injuries, including fractures of the phalanges, metacarpals, carpal navicular, lunate, and the Colles fracture, are described. Treatment by manipulation, traction, and immobilization is demonstrated, with emphasis on the basic principles of fracture reduction. The film includes a section of the after-care of wrist and hand fractures. Sound, 30 minutes.

Principles of Fracture Reduction.

VETERANS ADMINISTRATION, Washington, D. C.

This is a teaching film based purely on application of the fundamentals of the reduction of fractures by traction and suspension and an understanding of the anatomy in various fractures of the long bones. The anatomy is illustrated by animation. The film places emphasis on the fact that fractures are reduced by brains and not brawn. Sound, 30 minutes.

Hyperventilation: A Problem in Aviation Medicine?

BRUNO BALKE, Randolph Air Force Base, Texas.

This film shows the results of laboratory experiments to reveal the relationship between hyperventilation and psychomotor performance. Sound, 15 minutes.

Pheochromocytoma.

KEITH S. GRIMSON, Durham, N. C.

This film presents the signs and symptoms of tumors of the adrenal medulla. The use of drugs in diagnosis is stressed, especially the value of histamine in normotensive patients and of adrenolytic agents in persons with hypertension. Sound, 25 minutes.

Pheochromocytoma.

KENNETH C. SAWYER, WILLIAM M. M. ROBINSON, and ROBERT E. MCCURDY, Denver.

This film illustrates details in the successful management of a case of pheochromocytoma. A simplified technique for the exposure and removal of the tumor is shown. Silent, 17 minutes.

Antituberculosis Drugs in the Medical and Surgical Treatment of Tuberculosis.

H. CORWIN HINSHAW, San Francisco.

This film shows what can be accomplished frequently for tuberculosis patients when hospital care, together with antibacterial drug therapy, pulmonary collapse, and surgical resection are all brought to bear upon the problem when necessary. Sound, 22 minutes.

Complicated Appendicitis.

JAMES RIVES, New Orleans.

This film embraces the operative management of acute appendicitis in its predictable and less predictable locations and also the method of handling immediate and late complications. The errors in surgical technique are shown, and emphasis is placed on adequate exposure. Sound, 32 minutes.

Congenital Biliary Atresia.

ROBERT T. TIDRICK, Iowa City.

This film is devoted to the operative treatment of biliary obstruction in infancy. Cases of congenital atresia and posthepatitis ductal obliteration are presented. Various aids in operative evaluation are shown, with emphasis on cholangiography, injection of dilute methylene blue in the ducts, and liver biopsies with frozen sections. Sound, 32 minutes.

Wednesday morning, Nov. 30

Cancer of the Thyroid: Treatment of a Case by Radioactive Iodine.

American Medical Association, Chicago.

This film shows the diagnosis and management of a case of carcinoma of the thyroid with metastasis to the hip and its treatment with radioactive iodine. Sound, 7 minutes.

Lung Cancer: The Problem of Early Diagnosis.

American Cancer Society, New York.

Emphasis is placed on the differential diagnostic problems of patients with symptoms referable to the chest and particularly of patients in the early symptomatic stages of the disease. The practicing physician's examination of the patient is outlined in some detail, with emphasis on such things as complete x-ray studies and sputum cytology. The techniques of bronchoscopy and bronchial washings for cytology are shown. Sound, 30 minutes.

Radical Retroperitoneal Node Dissection in the Treatment of Testicular Tumor.

J. W. Schwartz and K. E. Van Buskirk, Washington, D. C.

Gross and microscopic germinal testicular tumors are shown and the treatment is outlined. The complete operation of radical retroperitoneal node dissection is demonstrated. Silent, 22 minutes.

Radical Surgery for Advanced Lung Cancer.

Adrian Lambert, New York.

The main portion of the film brings out the radical surgical approach to advanced lung cancer when the disease has progressed outside the lung into the chest wall and the mediastinum. The correct handling of this extensive disease is emphasized in order to give the patient the benefits of a possible cure. Sound, 32 minutes.

Cancer Detection.

Henry T. Randall, Emerson Day, George N. Papanicolaou, and Genevieve Bader, New York.

This is a Kinescope of a program originally produced for closed-circuit television by the American Cancer Society. A practical office cancer detection examination is demonstrated. Attention is devoted to methods of extending the range of early cancer accessible to office examination and to the role of the practitioner in the field of cancer control. Sound, 38 minutes.

Bilateral Adrenalectomy for Metastatic Carcinoma of the Breast.

Harold Masters, Beverly Hills, Calif.

The surgical technique of bilateral adrenalectomy is demonstrated. Cortisone requirements and preoperative and postoperative care is discussed. Sound, 22 minutes.

Panel discussion by: Andrew Jessiman, Boston.
O. H. Pearson, New York.
Grantley Taylor, Boston.
Norman Lenson, Boston.

Wednesday afternoon, Nov. 30

Abdominoperineal Resection for Cancer of the Rectum.

Charles G. Child III and Arthur J. Donovan, Boston.

This is a case-record orientational teaching film showing the extended scope of an abdominoperineal resection. The inferior mesenteric artery is ligated high. The pelvic nodes are extirpated and there is no reconstruction of the peritoneal floor.

Panel discussion by: J. Englebert Dunphy, Boston.
Claude Welch, Boston.
Kenneth W. Warren, Boston.

Questions from the audience will be invited.

Technique for Splenectomy.

John L. Madden, New York.

This film demonstrates a technique for performing a splenectomy on a typical patient with hypersplenism. The approach is made through an upper left paramedian incision; mobilization of the enlarged spleen includes dissection and removal of an accessory splenic nodule. A diagram illustrating the horizontal disposition of the peritoneum in the abdominal cavity has been inserted for orientation. Sound, 25 minutes.

Operative Clinic on Jaundice.

Francis D. Moore, Boston.

Cholecystectomy.

Richard B. Cattell, Boston.

In this film, the exposure is made through a right rectus muscle splitting incision with displacement of duodenum and head of pancreas to place the gastrohepatic omentum on a stretch. Demonstration of cystic, hepatic, and common ducts, as well as cystic and hepatic arteries, is essential before removal of the gallbladder, which is usually done from below upward. After decision relative to the necessity for common duct exploration the gastrohepatic ligament and gallbladder fossa is approximated. Sound, 32 minutes.

Thursday morning, Dec. 1

Action of Human Mitral and Aortic Valves Studied Post Mortem by Cinematography.

Ian K. R. McMillan, London, England.

This film is a cinematographic account of the mitral and aortic valves as revealed by postmortem studies of the human heart. Silent, 12 minutes.

Pericardiectomy for Constrictive Pericarditis.

John W. Strieder, Brookline, Mass.

This is a case record film demonstrating the difficulties entailed in pericardiectomy for constrictive pericarditis. Silent, 15 minutes.

Abdominal Aneurysm and Replacement with Homograft.

Herbert Adams, Boston.

This film demonstrates the technique of extirpation of an abdominal aneurysm and its repair with a homograft. The technique of sterilization of the graft by x-ray is also shown.

Surgical Treatment of Aortic Stenosis.

Dwight E. Harken and Harrison Black, Boston.

This film demonstrates the various types of aortic stenosis and their successful management by finger fracture.

Tetralogy of Fallot.

John C. Jones, Los Angeles.

This film explains the anatomic features of tetralogy of Fallot and shows the two types of shunting operations that are generally performed to supplement the inadequate flow of blood to the lungs. Sound, 32 minutes.

Treatment of Insidious Segmental Occlusion of the Femoral Artery by Resection and Homograft Replacement.

D. Emerick Szilagyi, Paul R. Overhulse, and Frank Zeller Jr., Detroit.

In the introductory remarks the clinical characteristics of insidious segmental arterial occlusion are briefly stated. The technical steps of the treatment of this lesion by resection and homograft replacement are shown. Some of the finer details of technique are explained with the aid of colored drawings. The role of angiography in diagnosis is pointed out. Sound, 28 minutes.

Ether Analgesia for Cardiac Surgery.

Joseph Artusio Jr. and Frank Glenn, New York.

A technique that makes it possible to maintain a patient in analgesia throughout major cardiac surgery is demonstrated. Five days after the operation, the patient is interviewed and shows that she has total amnesia for the procedure. Sound, 27 minutes.

Anomalies of the Aortic Arch.

George H. Humphreys II, New York.

The normal development of the aortic arch complex is shown in animation based on the work of Congden and others; x-rays and surgery of the operable anomalies are also included. The anomalies shown are patent ductus arteriosus, coarctation of the aorta, four variations of double aortic arch, right aortic arch, dysphagia lusoria, persistent truncus arteriosus, and a bizarre combined anomaly. Sound, 45 minutes.

Thursday afternoon, Dec. 1

Inguinal Hernia and Hydrocele in Infants and Children.

William L. Riker, Arthur De Boer, and Willis J. Potts, Chicago.

This film shows the basic facts about congenital inguinal hernia in infants and children. The embryology is illustrated with modified animation. Essentials for diagnosis are mentioned. Surgery is the treatment of choice and is amply illustrated on the operating table. Sound, 17 minutes.

Pruritus Ani.

Manuel G. Spiesman and Louis Malow, Chicago.

This film gives the authors' simplified classification of pruritus ani and the office and home treatments of each type. Color photographs show the various different pruritides and the application of treatment for each. The clover leaf operation for the intractable type is shown in detail. Silent, 34 minutes.

Routine Anorectal and Sigmoidoscopic Examination with Differential Diagnosis.

Malcolm R. Hill, Los Angeles.

The purpose of this film is to emphasize the importance of anorectal and colonic examination to show the simplicity with which it may be done, and to demonstrate the technique essential to an effective routine. Sound, 30 minutes.

Megacolon (Hirschsprung's Disease) Abdominoperineal Rectosigmoidectomy.

Harry E. Bacon, Philadelphia.

The film is chiefly a presentation of the author's technique in removing the dysfunctioning rectum of Hirschsprung's disease and transplanting the normal sigmoid colon to the anus, where it is anastomosed by the end-to-end technique to the normal rectum. A typical case is described with radiographic studies. A follow-up résumé indicates the success of the operation and return of bowel movements to normal regularity. Silent, 22 minutes.

Extraperitoneal Nephroureterectomy Through an Anterior Abdominal Incision.

Henry Bodner, Allan H. Howard, and Joseph H. Kaplan, Los Angeles.

The anterior abdominal retroperitoneal approach to the kidney is shown. A nephroureterectomy is done through this type of incision. In this manner, two incisions are obviated. Sound, 14 minutes.

Cinefluorography of the Urinary Tract.

Henry Bodner, Allan H. Howard, and Joseph H. Kaplan, Los Angeles.

This film shows motion picture x-ray fluoroscopy of an intravenous pyelogram demonstrating the physiology of the pelvis and ureter. Sound, 17 minutes.

Friday morning, Dec. 2

Prevention of Traumatic Tattoo and Repair of Soft Tissue Injury.

Richard C. Webster, Brookline, Mass.

This film shows an emergency reconstructive procedure carried out on a 3-year-old girl two hours after she was struck by an auto and thrown forcibly to the street. Injuries include traumatic tattoos of neck, shoulder, and back; avulsion of two-thirds of the ear, and deep communicating pockets of street dirt and grit under the scalp. The operation shows the vigorous removal of traumatic tattoos, the repair of the ear, and the cleaning and closure of the scalp pockets. Sound, 11 minutes.

Paracervical Uterine Denervation.

Joseph B. Doyle, Boston.

This is a case record film of the operative technique for paracervical uterine denervation as obtained essentially by cutting the uterosacral ligaments and peritoneal interposition. Sound, 20 minutes.

Orbital Mucoceles.

Hans Von Leden, Chicago.

This is a case record film that shows the diagnosis and surgical treatment for orbital mucoceles. The film shows x-ray sequences of diseased sinuses. Three operative sequences are shown, two of which demonstrate removal of mucoceles and one of which shows the removal of a benign tumor. Silent, 22 minutes.

Abdominal Pregnancy with Living Baby.

Milton L. McCall, New Orleans.

This film shows an abdominal pregnancy at full-term gestation. The patient has had four previous laparotomies, two for pelvic disease and two for intestinal obstruction. Partial intestinal obstruction was present during the present pregnancy. The diagnostic procedures, including history, pelvic examination, abdominal x-rays, hysterosalpingography, and tocography, are shown and the relative importance of each one emphasized. Laparotomy with delivery of living normal full-term infant is shown. Sound, 14 minutes.

Congenital Absence of the Vagina and Its Treatment.

Joseph Gaster, Beverly Hills, Calif.

This is a presentation of two cases showing the embryology and anatomy of congenital absence of the vagina with films taken before, during, and after operation. Both patients had rudimentary uteri, and one patient had a fibroid tumor on a rudimentary uterus. Sound, 25 minutes.

The Rizzoli-Stone Operation for Correction of Atresia Ani Vaginalis.

John G. Matt, Tulsa, Okla.

This motion picture demonstrates the Rizzoli-Stone operation being utilized to correct a case of atresia ani vaginalis. Several slight modifications that have been found to make the operation easier and that yield a better final result are demonstrated. The film also demonstrates the proper technique of using a closed method of anesthesia in pediatric surgery. Sound, 18 minutes.

SPECIAL EVENING FILM PROGRAM: GEORGIAN ROOM, HOTEL STATLER

Wednesday evening, Nov. 30

8:00 p.m.

Myasthenia Gravis: Diagnosis, Treatment, and Management.

Myasthenia Gravis Foundation.

Introduction by Henry R. Viets, Boston.

In this film the incidence of the disease, history behind the present successful diagnosis and treatment, the various tests used in diagnosis, and the clinical course of the disease are discussed. In the section on treatment, the use of prostigmin, mestinon, and mysuran and the great variance in dosage from patient to patient is shown. The management of both cholinergic and myasthenic crises is demonstrated.

Total Right Hepatic Lobectomy.

George T. Pack and Richard D. Brasfield, New York.

Introduction by George T. Pack, New York.

This film demonstrates the authors' technique for removal of the entire right lobe of the liver for cancer in a case where the remaining lobes and the hepatic fissure were not involved by the neoplasm. The patient is shown three months postoperatively.

Note: Mr. Cutler's address to the House of Delegates will be heard by loud speaker in the Georgian Room immediately following Dr. Pack's presentation.

THE SCIENTIFIC EXHIBIT

The Scientific Exhibit will be located in Grand Hall on the main floor of Mechanics' Building, adjacent to the main lecture hall. It will be reached by entrances from the Technical Exposition.

The Council on Scientific Assembly has arranged several features, including the Special Exhibit on Fractures, Manikin Demonstrations on Problems of Delivery, and Demonstrations on Diabetes. In connection with the latter, there will be Question and Answer Conferences on Diabetes daily on the second floor.

The Scientific Exhibit will open Tuesday morning, Nov. 29, at 9 a. m. and will close Friday, Dec. 2, at 12:30 p. m. On the intervening days it will be open from 8:30 a. m. to 5:30 p. m.

The office of the Council on Scientific Assembly will be located in Space 101 in the Scientific Exhibit.

SPECIAL EXHIBIT ON FRACTURES

The Special Exhibit on Fractures is presented under the auspices of the following committee:

Ralph G. Carothers, Cincinnati, chairman.
Herbert W. Virgin Jr., Miami, Fla.
Harry B. Hall, Minneapolis.
Gordon M. Morrison, Boston, emeritus.

Continuous demonstrations will be conducted daily from 9 a. m. to 12 noon and from 2 p. m. to 4 p. m. from Tuesday morning to Friday noon on the following subjects:

Fractures of the Ankle.

Fractures Resulting from a Fall on the Outstretched Hand.

Traction for Arm and Leg.

Basic principles will be stressed, with particular emphasis on the interest of the physician in general practice. Ample opportunity will be allowed for questions, and members of the committee will be present to discuss individual problems with visiting physicians.

A pamphlet giving the essential features of the exhibit has been prepared for distribution.

An outstanding group of surgeons will assist the Committee in the presentation of the exhibit.

PROBLEMS OF DELIVERY—MANIKIN DEMONSTRATIONS

Manikin demonstrations on problems of delivery will be conducted at stated intervals throughout the week by outstanding obstetricians. An opportunity for questions and answers will be given after each demonstration.

Robert H. Barker, Boston, is chairman of the group in charge of demonstrations. The following schedule will be presented:

Tuesday, Nov. 29

1:00 p. m. **Breech Deliveries.**
John W. Schleicher, Hanover Clinic, Hanover, N. H.

4:30 p. m. **Outlet Forceps.**
Crawford H. Hinman, Brookline, Mass.

Wednesday, Nov. 30

10:30 a. m. **Persistent Occiput Posterior.**
John L. Newell, Brookline, Mass.

1:00 p. m. **Deep Transverse Arrest.**
Daniel Abramson, Boston.

Thursday, Dec. 1

10:30 a. m. **External and Internal Podalic Versions.**
Robert Lorimer, Portland, Maine.

1:00 p. m. **Breech Deliveries.**
John W. Schleicher, Hanover Clinic, Hanover, N. H.

4:30 p. m. **Persistent Occiput Posterior.**
Francis Rouillard, Boston.

Friday, Dec. 2

10:30 a. m. **Persistent Occiput Transverse.**
Daniel H. Hindman, Boston.

DIABETES CONFERENCES

In addition to an extensive exhibit on Diabetes Today, there will be a series of question and answer periods on diabetes and its treatment daily from 11 a. m. to 1 p. m. These conferences are sponsored by the Joslin Clinic under the direction of Howard F. Root, Boston.

Emphasis is placed on the fact that questions will be invited from the audience.

The program follows:

Tuesday, Nov. 29

11:00 a. m. **The Insulins.** Leo P. Krall, Boston.

11:30 a. m. **Diabetic Acidosis and Coma.**
Howard F. Root, Boston.

12:00 noon **Panel Discussion on Problems in Treatment.**
Nature of Diabetes. Leo P. Krall, Boston.

Choice of Insulins.
Alexander Marble, Boston.

Hypoglycemic Encephalopathy.
Howard F. Root, Boston.

Wednesday, Nov. 30

11:00 a. m. **Pregnant Diabetics.** Priscilla White, Boston.

11:30 a. m. **Diet and Insulin.** Allen P. Joslin, Boston.

12:00 noon **Panel on Diabetes in Youth.**
Pregnancy. Priscilla White, Boston.

Children of Diabetic Parents.
Howard F. Root, Boston.

"Brittle" Diabetes. Luke Gillespie, Boston.

Thursday, Dec. 1

11:00 a. m. **Treatment of Early Cases of Diabetes.**
Allen P. Joslin, Boston.

11:30 a. m. **Control of Diabetes.** Alexander Marble, Boston.

12:00 noon **Panel Discussion on Treatment of Complications.**
Ocular. Alexander Marble, Boston.

Vascular. Robert F. Bradley, Boston.

Acidosis. Allen P. Joslin, Boston.

Cushing's Syndrome.

R. G. Sprague, J. T. Priestley, Waltman Walters, R. V. Randall, R. M. Salassa, and D. A. Scholz, Mayo Clinic and Mayo Foundation, Rochester, Minn.

Cushing's syndrome in its severe form is a serious condition that impairs survival and is associated with a high degree of morbidity. While its remote causes have not yet been accurately ascertained, it is now well established that the condition is a direct consequence of excessive secretion of steroid hormones by hyperplastic or neoplastic adrenal cortices. No form of medical treatment in our hands has been uniformly effective. The exhibit is based upon 100 cases of Cushing's syndrome studies at the Mayo Clinic and consists of (1) a description of the clinical manifestations of the syndrome, (2) a summary of laboratory and x-ray findings, (3) a review of theories of its pathogenesis and the salient features of its endocrine pathology, and (4) a description of the surgical treatment in patients who have either tumors or hyperplasia of the adrenal cortex, with data and photographs illustrating results of such treatment.

Esophagitis: A Common Condition Frequently Overlooked.

H. W. Schmidt, F. H. Ellis Jr., A. M. Olsen, J. H. Grindlay, and A. H. Bulbulian, Mayo Clinic and Mayo Foundation, Rochester, Minn.

Esophagitis is a relatively common disorder that is frequently overlooked. It usually occurs in association with conditions that produce or permit regurgitation of gastric contents. Thus, the causes of vomiting may be etiological factors in the production of esophagitis. Incompetence of the sphincteric mechanism at the cardia is also an important factor. Such cardial incompetence occurs frequently with esophageal hiatal hernia and as a complication of surgical procedures that destroy the cardial mechanism. This exhibit presents (1) typical case reports illustrating various conditions producing esophagitis; (2) pathological specimens, photomicrographs, and esophagoscopic photographs of esophagitis in man; (3) methods for the experimental production of esophagitis and surgical techniques designed to prevent esophagitis; and (4) various methods of treating esophagitis and its complications.

Serum Glutamic Oxalacetic Transaminase Variations in Heart and Liver Disease.

John S. La Due and Felix Wroblewski, Sloan-Kettering Institute, Research Division of Memorial Center, New York.

The variations in serum glutamic oxalacetic transaminase activity in experimental myocardial infarction, ischemia, and streptococcic toxic myocarditis will be compared with the serum enzyme changes observed in clinical myocardial infarction, coronary insufficiency, and rheumatic carditis. The dynamic changes in serum glutamic oxalacetic transaminase activity in experimental toxic and viral hepatitis will be compared with the changes observed in clinical carbon tetrachloride poisoning and infectious and homologous serum hepatitis. The variations in serum glutamic oxalacetic transaminase activity in cirrhosis and the significance of the increased activity in metastatic carcinoma to the liver will be demonstrated.

Diagnosis by Gastroscopy—Hemorrhagic Lesions in the X-ray Negative Stomach.

Emmanuel Deutsch and Daniel L. Shaw Jr., Tufts College Medical School, Boston.

When a definite bleeding point during gastric hemorrhage is not discovered by x-ray, then gastroscopy can be of considerable help. This exhibit includes slides of drawings showing acute mucosal ulceration and multiple erosions, sliding hiatus hernia, a small broad-based polyp; gastric purpura, anastomotic ulcer, ectasia of gastric mucosa, and a circumscribed carcinomatous ulcer. It also illustrates the value of gastric biopsies and aspiration taken during gastroscopy. The mechanism and clinical features of gastric hemorrhage in the stomach, that is normal on x-ray, are presented together with illustrative cases.

Corticotropin Zinc Hydroxide (Zinc ACTH) in the Collagen Diseases.

Harry E. Banghart and Richard K. D. Watanabe, Hahnemann Medical College and Hospital and Germantown Hospital, Philadelphia.

An evaluation of the effectiveness of a suspension of corticotropin zinc hydroxide in the long-term management of acute disseminated lupus erythematosus (8 cases), dermatomyositis (2 cases), undifferentiated collagen disease (6 cases), and intractable rheumatoid arthritis (22 cases). Data are presented on the effectiveness of the agent in the control of the diseases, dosage required for suppression of the acute symptoms and for the maintenance of this suppression, the duration of action of a single dose of the hormone, and the length of time that repeated doses of the hormone were effective. There are also data on indications and contraindications for the hormone together with studies of its effects on electrolytes, blood sugar, and peptic ulcer and a comparison with corticotropin gel.

Diagnosis of Hemorrhagic Disorders.

Mario Stefanini and James H. Graham, *St. Elizabeth's Hospital and Tufts College Medical School, Boston.*

The exhibit outlines the evaluation of the patient with bleeding disease and briefly describes basic tests to be performed for its proper classification and treatment. A series of diapositives seen through a plastic box shows various clinical and laboratory aspects of hemorrhagic disorders. A schematic description is presented of a series of hemorrhagic disorders of general clinical interest, including vascular purpura, drug purpura, dysproteinemias, fibrinolytic purpuras of gastric, pancreatic, prostatic carcinoma, hemorrhagic accidents of pregnancy, and hemorrhagic accidents following multiple transfusions.

Use and Action of New Long-Acting Corticotropin Preparations—Treatment of Rheumatoid Arthritis.

Heinrich G. Brugsch, Harold S. Rubin, and Edward H. Frieden, the New England Medical Center, Boston.

Charts and drawings demonstrate (1) methods of preparation of corticotropin; (2) methods of assay; (3) effects upon eosinophil count and oxyketosteroids of various preparations; (4) comparative clinical data on effectiveness and duration of aqueous corticotropin, corticotropin gel, and corticotropin zinc; (5) side-effects; and (6) contraindications.

Hypersensitivity as a Mechanism in Vasculitis.

Robert P. McCombs, James F. Patterson, and H. Edward MacMahon, New England Center Hospital, Boston.

The exhibit shows color photographs (transparencies) of skin lesions and photomicrographs of material obtained from these lesions or similar areas at autopsy. In all cases a vasculitis was present. Cases have been selected in which the history strongly suggested that some form of hypersensitivity played an important role in the production of the lesions. Abstracts of the case histories and descriptive material are arranged about the color transparencies.

Prevention of Streptococcic Infection and Rheumatic Fever with Orally Given Penicillin.

Joseph M. Miller, Melvin S. Kaplan, and Benedict F. Massell, House of the Good Samaritan and Harvard Medical School, Boston.

The role of group A hemolytic streptococcic respiratory infection in relation to both initial attacks and recurrences of rheumatic fever will be demonstrated. Original data will be shown regarding attack rates of rheumatic fever after group A hemolytic streptococcic infections prior to the availability of penicillin. The results of controlled studies concerning the applications of penicillin will be demonstrated. The effectiveness of continuous daily oral administration of penicillin will be shown by data on the incidence of group A streptococcic infections among ambulatory rheumatic subjects receiving such prophylaxis and among siblings of these rheumatic subjects for whom daily doses of penicillin were not prescribed.

Blood and Bone Marrow Patterns in the Differential Diagnosis of Disease.

G. Douglas Talbott, Elmer Hunsicker, and Jonah Li, 2750th Hospital, Wright-Patterson Air Force Base, Dayton, Ohio.

This exhibit presents in a concise fashion the principal diagnostic features of many of the important hematological disorders. Patterns rather than cell morphology are stressed. These patterns are illustrated by color transparencies.

Uncommon Heart Diseases.

R. O. Brandenburg, J. E. Edwards, T. J. Dry, and Daniel C. Connolly, Mayo Clinic and Mayo Foundation, Rochester, Minn.

The causes of heart disease are numerous and varied, but approximately 97% is of hypertensive, coronary, or rheumatic origin. Congenital anomalies of the heart constitute about 1% of cardiac disease. There remains a very small group of patients in whom heart disease develops as a result of conditions that are widely diverse and sometimes obscure in origin. The valves, the myocardium, or the pericardium may be involved. The principal manifestation of these rare cardiac disturbances may be difficult to distinguish from those of the common cardiac diseases. For the sake of convenience these rare types of heart disease may be classified as follows: (1) conditions stimulating mitral valvular disease of rheumatic origin, (2) conditions simulating aortic valvular diseases of the usual types, (3) conditions causing myocardial disorders of acute or chronic types, and (4) conditions causing pericarditis of acute or chronic types.

Drug Therapy in Peripheral Vascular Disease.

Irwin D. Stein, Mount Vernon Hospital, Mount Vernon, N. Y.

A distinction must be made between vasodilating drugs that act on vessels of the skin and those that act on muscle. Most of the ganglionic-blocking agents are primarily skin vasodilators and should be employed in the treatment of areas where skin circulation predominates or where a specific effect on such a region is desired, as in the prevention of trophic changes in the digits, the management of Raynaud's phenomena and of sweating, or therapy of ulcerating lesions of the hands and feet. In comparison, there are far fewer measures that have an influence on intermittent claudication, the major symptom of muscle ischemia. With the aid of clinical tests, oscillometry, the measurement of temperature and skin resistance, and the use of the plethysmograph, this distinction between vasodilating measures in common use has been made.

Surgical Treatment of Mitral and Aortic Stenosis.

Dwight E. Harken, Harrison Black, Hugh E. Wilson, and Warren J. Taylor, Peter Bent Brigham Hospital, Boston.

Transparencies demonstrate the pathology of mitral stenosis and mitral insufficiency and the surgical technique for correcting these lesions, and charts demonstrate the differential diagnosis, the preoperative and postoperative care, and an analysis of results in a pilot study of our first 500 valvuloplasties. In addition, there are exhibit books containing illustrations that elaborate on the above subjects as well as describe miscellaneous cardiac procedures, including a new and rational approach to angina pectoris.

Hypertension—Pharmacodynamics of Therapy.

John H. Moyer, Edward W. Dennis, and Ralph V. Ford, Baylor University College of Medicine, Houston, Texas.

The exhibit centers around the pharmacodynamics of various drugs that are used for the treatment of hypertension. An attempt will be made to (1) show how drug responses of hypertensive patients gives information relative to etiological factors in the origin of hypertension, (2) demonstrate renal responses to blood pressure reduction with various antihypertensive agents, especially pentolinium, (3) present an animated illustration of the origin of hypertension and the sites of drug action when treating this disease, and (4) present the clinical application of these principles for the practicing physician.

Resection and Grafting in Treatment of Occlusive Arterial Diseases Affecting the Lower Limb.

D. Emerick Szilagyi, Roger F. Smith, Claibourne P. Shonnard, Nicholas P. D. Smyth, and Gerald A. Lo-Grippo, Henry Ford Hospital, Detroit.

The clinical material on which the exhibit is based consists of 50 cases of segmental occlusive disease of the femoropopliteal and aortoiliac areas treated with resection of the diseased segment and replacement by wet-preserved and lyophilized sterilized homografts. In transparencies of photographs, artist's drawings, and charts, the exhibit portrays the important clinical characteristics of the arterial lesions, the diagnostic procedures (in particular, angiography) essential for their identification, the salient surgical techniques, and the therapeutic results. A pictorial summary of methods of graft procurement and storage particularly suited to the needs of smaller hospitals is included.

Tuberculosis—Every Hospital's Problem.

Frances Kord, Massachusetts Tuberculosis and Health League, Boston.

The problem of unrecognized tuberculosis is shown, with emphasis upon the fact that many cases of unsuspected tuberculosis exist among patients admitted to general hospitals. The danger of caring for persons with unidentified tuberculosis is brought out. The answer to the problem is routine chest x-ray examination of patients at admission and hospital employees.

Differential Diagnosis in Pulmonary Disease.

Frank W. Webster, National Tuberculosis Association and American Trudeau Society, New York.

The exhibit centers around six illuminated chest x-ray plates, each showing a different kind of chest pathology. Viewers are invited to attempt to diagnose the pathology shown in each plate by pressing a button opposite the name of the disease that they believe is involved. If the correct button is pressed, a typed case history above the chest x-ray concerned is illuminated. The exhibit is intended to show that a correct diagnosis can seldom be made from an x-ray alone and that the use of a number of other diagnostic procedures is invariably required.

Tuberculosis of the Skin in Long-Term Observations After Therapy with Isonicotinic Acid Hydrazide.

Robert F. Tilley and John Adams Jr., Massachusetts General Hospital and Harvard Medical School, Boston.

A group of patients with various types of tuberculosis of the skin were treated for one year with isoniazid (isonicotinic acid hydrazide). The exhibit consists of the results one to two years after completion of the treatment. Histological studies, bacteriological procedures, and clinical appraisals were utilized. The results are demonstrated by means of color photographs taken before, during, and after therapy.

Effects of Antimicrobial Therapy of Pulmonary Tuberculosis.

Shirley H. Ferebee and Frank W. Mount, Tuberculosis Program, Division of Special Health Services, Public Health Service, U. S. Department of Health, Education, and Welfare, Washington, D. C.

The exhibit presents a graphic comparison of x-ray change, sputum conversion, and bacterial resistance among patients treated with seven combinations of streptomycin, aminosalicylic acid, and isoniazid.

Chronic Pulmonary Emphysema: *Classification, Physiopathology, and Management.*

Maurice S. Segal, Ernst O. Attinger, and Merrill M. Goldstein, Tufts College Medical School and Boston City Hospital, Boston.

The exhibit shows clinical classification, pathological studies, radiological studies, and pathophysiological data with particular reference to complete pulmonary function studies that include catheterization of the right side of the heart and the mechanics of breathing. There is also included the pathological-physiology, correlated with the specific physiological management for each defect. The data obtained from a typical completely examined patient are illustrated.

Lipoprotein Research.

LAWRENCE J. MILCH, United States Air Force School of *Aviation Medicine, Randolph Air Force Base, Texas.*

The exhibit depicts by the use of charts and photographs the methods of measuring lipoproteins and findings in various disease and injury states.

Evaluation of Poliomyelitis Vaccine.

HART E. VAN RIPER, National Foundation for Infantile Paralysis, Inc., New York.

This exhibit shows the evaluation of vaccine for poliomyelitis and the methods used.

Periodic Health Appraisal: Methods and Results.

ROBERT J. BOLT, O. T. MALLERY JR., and CHARLES J. TUPPER, University of Michigan, Ann Arbor, Mich.

This exhibit demonstrates the methods employed and the results of complete annual checkup examinations. The study includes a period of five years during which 943 examinations were done. Details are given of the methods employed and the type of studies utilized as routine procedures. The results of the examinations are depicted. In addition the manner in which the various diagnoses were made is listed, and the value of the various laboratory and x-ray procedures utilized are analyzed.

At Birth Diphtheria-Pertussis-Tetanus Immunization.

HERBERT D. CHAMBERLAIN, Ohio Academy of General Practice, McArthur, Ohio.

Charts and posters show an experiment over the past six years of immunizing newborn infants with a standard preparation of diphtheria-pertussis-tetanus vaccine.

Systematic Approach to Fluid Balance.

W. D. SNIVELY JR. and M. J. SWEENEY, Evansville, Ind.

This exhibit presents in a simplified manner the underlying principles of clinical fluid balance. It provides "knowledge pegs" upon which to hang the multitude of details required for a working knowledge. A descriptive system of diagnosis based on suggestions by Moyer is presented. The basic imbalances include deficits and excesses in volume, concentration, composition, and distribution of the extracellular fluid that reflect intracellular changes. Each deficit and excess is described as its clinical cause, clinical findings, laboratory findings, and therapy principle. A simple analogy clarifies the use of the milliequivalent. The "teeter totter" method of explaining acid-base imbalances, as introduced by Dr. Snively, is employed in this exhibit to explain acid-base imbalances. Gains and losses of body fluids are presented pictorially. Electrolyte composition of the several body fluids is charted and compared. The seven major functions of parenterally given solutions and the electrolyte content of parenterally given solutions as compared to plasma are presented.

Diabetes Today.

HOWARD F. ROOT, ELLIOTT P. JOSLIN, PRISCILLA WHITE, ALEXANDER MARBLE, ALLEN P. JOSLIN, LEO P. KRALL, and ROBERT F. BRADLEY, New England Deaconess Hospital, Boston.

Placards present data on the treatment of diabetic coma, pregnancy in diabetic patients, diabetes of long duration, and causes of death.

Foetal and Neonatal Morbidity and Mortality.

ALICE M. GOODFELLOW, D. H. BOWDEN, J. NORRIS, and J. L. BLAISDELL, the Research Institute of the Hospital for Sick Children, Toronto, Canada.

The purpose of the exhibit is to demonstrate the important causes of fetal and neonatal mortality and morbidity. Emphasis is placed on preventive and therapeutic measures that may reduce the death rate in this age group. The development of the fetus is depicted in chronological manner in order to present a panoramic picture of fetal and neonatal pathology.

Penicillin Reactions.

CLARENCE A. SMITH and MAURICE KAMP, Division of Special Health Services, Public Health Service, U. S. Department of Health, Education, and Welfare, Washington, D. C.

The incidence of penicillin reactions in over 19,000 patients treated for venereal disease was less than 1%. This incidence is broken down by race, age, sex, and previous treatment with penicillin.

Kerosene Poisoning in Young Children.

A. BRADLEY SOULE JR. and JOSEPH C. FOLEY, University of Vermont College of Medicine, Burlington, Vt.

The accidental ingestion of kerosene results in the commonest form of poisoning in children under the age of 2 years in rural and semirural areas of northern Vermont, as indicated by this study of 150 children admitted to local hospitals during a 10-year period. Approximately half of the children developed pneumonitis, and three died. The exhibit includes serial chest roentgenograms of several typical cases and brief descriptions of clinical and roentgenologic features of the condition with suggestions for management. It also includes presentation of experimental material that indicates that pulmonary changes noted in kerosene poisoning apparently result from aspiration of kerosene rather than from absorption from the alimentary tract.

The Malignant Carcinoid Syndrome—A New Metabolic Disorder.

ALBERT SJOERDSMA, LUTHER L. TERRY, and SIDNEY UDENFRIEND, National Heart Institute, National Institutes of Health, Bethesda, Md.

The exhibit consists of an outline of the human figure showing the anatomic location of the characteristic clinical manifestations of this syndrome. About this figure are colored transparencies showing a patient before and during a characteristic flush and photomicrographs of the carcinoid tumor, as well as charts depicting the other characteristic manifestations. There is also a diagrammatic demonstration of the abnormality of tryptophan metabolism that is responsible for many of the clinical signs and symptoms. Important metabolic studies that have allowed a characterization of this disorder are included.

Thymectomy for Myasthenia Gravis: Anesthetic Management.

JAMES L. VANDERVEEN, Massachusetts General Hospital, Boston.

Posters point out the special anesthetic problems associated with myasthenia gravis. Photographs show the present technique of anesthetic management, including preparation and postoperative management. A discussion, in chart form, of the results of the use of this and other techniques cover experience with over 100 thymectomies extending from 1941 to 1955.

Thymectomy for Myasthenia Gravis: Selection and Supervision of Patients and the Evaluation of Results.

HENRY R. VIETS and ROBERT S. SCHWAB, Massachusetts General Hospital, Boston.

The exhibit presents (1) selection of patients for thymectomy from a group of 400 patients with myasthenia gravis; (2) preoperative regulation of medication, intravenous requirements during operation, and controlling the patient after surgery; (3) selection and evaluation of match controls for comparison with those who have undergone thymectomy; and (4) general results.

Thymectomy for Myasthenia Gravis: Pathology of the Thymus Gland.

BENJAMIN CASTLEMAN, Massachusetts General Hospital, Boston.

The changes in the thymus gland of patients with myasthenia gravis are exhibited, including photographs of specimens removed surgically, thymomas and hyperplasias, and photomicrographs showing the variations in the histology.

Thymectomy for Myasthenia Gravis: Surgical Aspects.

Richard H. Sweet and Oliver Cope, Massachusetts General Hospital, Boston.

The exhibit presents the important aspects of the operative preparation and includes the details of anesthesia and prostigmin administration during operation. Drawings of actual technique are included, together with color transparencies showing typical appearance of thymus at operation and the microscopic characteristics. Charts show important aspects of postoperative care such as prostigmin administration, management of respiratory passage, and comments on causes of postoperative death and how to avoid it.

Clinical Basis of Parkinson Therapy.

Lewis J. Doshay and William Amols, Columbia-Presbyterian Medical Center, New York.

The exhibit presents a comprehensive and practical program of Parkinson therapy. It provides the posology, actions, side-effects, and best methods of administering the standard drugs, such as scopolamine, diphenhydramine, cycrimine, trihexyphenidyl, benztropine, reserpine, chlorpromazine, and other compounds, singly and in combination. A plan is offered for the proper orientation and management of the Parkinson patient, including basic measure of psychotherapy. Physical therapy is discussed in its broadest aspects. The indications for surgical therapy are given consideration.

Senile Degenerations of the Brain and Their Relation to Psychoses and Disease.

George S. Strassmann, Metropolitan State Hospital, Waltham, Mass.

Specimens and photographs are shown from autopsies performed on mentally sick patients over 60 years old, showing (1) nervous system (hemorrhages, thromboses, tumors, meningitis, subdural hemorrhages, and lobotomy); (2) cardiovascular system (aortic thromboses, aneurysm, rupture, endocarditis, and pericarditis); (3) respiratory system (tuberculosis, anthracosis, pneumonitis, empyema, and pulmonary embolism); (4) gastrointestinal tract (peptic ulcers, tumors, diverticula, liver cirrhosis, and gallstones); and (5) other tumors and diseases (pyelonephritis, cancer of prostate, ovaries, and uterus).

Pharmacological Management of Everyday Psychiatric Problems.

Frank J. Ayd Jr., Baltimore, Md.

The exhibit presents the physiological basis for the more common symptoms manifested by the nonhospitalized psychiatric patient. This is followed by an explanation of the pharmacological action of reserpine and the rationale for its use in these patients. The exhibit outlines the use of reserpine in the management of the emergency psychiatric patient whom the physician frequently sees at home. This is followed by the description of the nondisturbed patient seen at the office and the use of reserpine in the management and treatment of this type of patient. The side-effects of reserpine and their management concludes the exhibit.

Improving Senile Behavior with Reserpine/Ritalin—A New Approach.

John T. Ferguson, Traverse City State Hospital, Traverse City, Mich.

The exhibit concerns itself with the oral administration of a new drug combination (reserpine and Ritalin) to 215 patients over 60 years of age. The largest portion of the group studied had some degree of deteriorated senile or arteriosclerotic change, with the subsequent mental symptoms and behavioral pattern associated with these changes. Behavior was evaluated by an 11-point check system. A reduction in original abnormal behavior was achieved in 171 of the 215 patients, while 44 remained essentially the same.

Mental Disorders in the United States: Some Indications of the Size and Scope of the Problem.

William P. Shepard, Earl C. Bonnett, and Herbert H. Marks, Metropolitan Life Insurance Company, New York.

Charts show (1) current statistics and trends in prevalence, incidence, and hospitalization of persons with mental disorders and hospital facilities available for their treatment; (2) the short-term and long-range outlook for persons with mental disorders; and (3) an outline of major community needs and trends relating to care of persons with emotional or mental disorders. The exhibit brings out the extent to which the steady increase in the number of patients hospitalized for mental disease is accounted for by the growth of the population, especially of older persons, by the reduction in mortality of these patients, and other factors. It also presents the results of new research into the longevity of persons with mental and personality disorders.

Thrombosis of the Carotid Artery.

Maurice L. Silver, Miriam Hospital, Providence, R. I.

With the widespread use of cerebral angiography, the diagnosis of carotid artery thrombosis is appearing with greater frequency. This condition explains the appearance, in the age group 30-50, of progressive hemiplegia with or without aphasis. Typical cases are presented, and the characteristic x-ray pictures are demonstrated. The etiology and pathology are discussed, and the treatment by medical and surgical means presented. Beneficial results following resection of the superior cervical ganglion would appear to warrant further trial of this therapy.

Management and Rehabilitation of Emotionally Maladjusted Children.

James A. Flaherty, Governor Bacon Health Center, Delaware City, Del., and Robert L. Gatski, Danville State Hospital, Danville, Pa.

The exhibit deals with the problem and present-day management of severely and chronically disturbed children in a residential treatment center. It points up the need for recognition and treatment in the early states of the disturbance. Charts, graphic analyses, and representative case histories summarize experience with chlorpromazine as an adjunct to treatment.

The Helping Hand—Rehabilitation of the Psychiatric Patient.

Delilah Riemer, Hugh E. Kilmartin, Walter Feri, Charles Kinnard, Raymond Nilson, Harold Shalik, and Raymond Slater, Veterans Administration Hospital, Bedford, Mass.

This exhibit demonstrates ways to bring about the rehabilitation of the psychiatric patient through one or more programs for short-term and continued treatment of regressed and general medical and surgical patients. The objectives to accomplish these programs are essentially the same for all the therapies and are directed toward the relief of mental and physical symptoms and signs. In the rehabilitation of the psychiatric patient, the therapies of the physical medicine and rehabilitation service work with the entire rehabilitation team. They use their respective modalities and activities as tools of treatment directed toward achieving one of three levels of rehabilitation; namely, increased independence during hospital living, sheltered living, and full community living.

Tic Douloureux—Treatment by Injection of Boiling Water into the Gasserian Ganglion.

Rudolph J. Jaeger, William H. Whiteley, and David J. La Fia, Jefferson Hospital, Philadelphia.

During the past two years a technique has been used for controlling the pain of tic douloureux and cancer of the face by the destruction of the gasserian ganglion cells with boiling water. Cases have been purposely selected because of the poor operative risk involved. The results have been equal if not superior to the operative methods of controlling this disorder, but this method requires certain meticulous technical details in order to be successful and avoid complications. The technique and postoperative results are shown by the exhibit.

Effects of Chlorpromazine on Acute and Postalcoholic States.

JOSEPH F. FAZEKAS and JAMES G. SHEA, District of Columbia General Hospital, Washington, D. C.

The exhibit reviews laboratory and clinical results with chlorpromazine in more than 500 alcoholic patients. It is based on data derived from studies on (1) the influence of chlorpromazine and alcohol on cerebral hemodynamics and metabolism, (2) the use of chlorpromazine in patients with head injuries associated with alcoholism, and (3) the efficacy of chlorpromazine in relieving psychomotor excitement and nausea and vomiting in acute alcoholic states.

Modern Concepts in the Therapy of Chronic Alcoholism.

EBBE C. HOFF, J. DAVID MARKHAM, and MARVIN C. BECKER, Virginia Division of Alcohol Studies and Rehabilitation, Medical College of Virginia Hospital, Richmond, Va.

The exhibit outlines present methods in treatment and rehabilitation of chronic alcoholics by private physicians. It includes selection of patients and gives a detailed demonstration of Antabuse-alcohol reaction by using a manikin, together with the role of Antabuse in treatment, follow-up treatment, prognosis, and results.

Pheochromocytomas—A Clinicopathological Analysis of Thirty-Eight Cases.

MEYER M. MELICOW, Squier Urological Clinic, Columbia-Presbyterian Medical Center, New York.

The exhibit is divided into three parts: (1) clinical studies showing cases associated with paroxysmal hypertension, cases associated with sustained hypertension, and a miscellaneous group in which diagnosis was made at operation or autopsy; (2) pharmacological studies showing the analysis of laboratory findings in relation to clinical behavior and wherever possible to pathological findings; (3) pathological studies showing intra-adrenal pheochromocytomas, multiple pheochromocytomas, extra-adrenal pheochromocytomas, and histology with benignity versus malignancy and hibernating fat.

Treatment of Gastric Cancer.

GEORGE T. PACK, GORDON P. MCNEER, KATHLEEN E. ROBERTS, DOUGLAS A. SUNDERLAND, LOUIS G. ORTEGA, and HENRY T. RANDALL, Memorial Hospital, New York.

The exhibit covers three phases in the treatment of cancer of the stomach: (1) pathological studies based on autopsy and investigation of specially cleared surgical specimens for lymph node distribution of metastasis, with certain conclusions regarding surgical technique; (2) metabolic changes in humans after total gastrectomy; and (3) end-results of treatment.

Carcinoma of the Lung.

HERBERT D. ADAMS, DAVID P. BOYD, and CARLTON H. SOUDERS, Lahey Clinic, Boston.

This exhibit covers general statistical data elicited from a detailed study of over 400 cases of bronchogenic carcinoma. Causes of delay in diagnosis and treatment are stressed. Color photographs feature surgical procedure, emphasizing diagnosis and pathological consideration and including lesions confused with cancer of the lung. Therapy, including pneumonectomy combined with super voltage x-ray therapy, is presented.

Investigative Approaches to the Lung Cancer Problem.

EMERSON DAY, WILLIAM G. CAHAN, LEOPOLD G. KOSS, ERNEST L. WYNDER, HOLON W. FARR, GEORGE N. PAPANICOLAOU, and WALTER E. O'DONNELL, Memorial Center, New York.

The investigative approaches to the lung cancer problem is considered from three standpoints. The first is epidemiological and environmental. This includes a summary of all the environmental factors, especially cigarette smoking, which have been established as playing an important role in the pathogenesis of lung cancer and particularly in its recent sharp rise in incidence. Studies done both at this institution and elsewhere are summarized. The differences and relative advantages of the retrospective and prospective studies are considered. The second standpoint is laboratory, and the means by which tobacco tar is currently being subjected to biological testing on laboratory animals is depicted. The various methods of establishing the carcinogenicity of the various fractions of tobacco tar with a view toward their eventual modification or removal from human exposure are depicted. From the clinical standpoint, representative study of the clinical effect of the long-term smoking habit on human respiratory mucosa is illustrated.

Carcinoma of the Larynx: Study Based on Twenty-Five Years' Experience.

CHEVALIER L. JACKSON, JOHN V. BLADY, and CHARLES M. NORRIS, *Temple University Hospital, Philadelphia.*

The exhibit shows transparencies of indirect and direct laryngoscopic views and operative specimens and the varied appearances of carcinoma of the larynx and laryngopharynx. Criteria for the selection of treatment are to be presented in relation to end-results. Management of "precancerous" lesions as well as early and advanced cancer is included.

Adenomas of the Colon and Rectum.

ROBERT TURELL, ROBERT PARADNY, and AUBRE DE L. MAYNARD, New York.

This exhibit deals with the incidence, distribution, types, genesis, familial tendency, cancer potential, and treatment of discrete, single, or multiple scattered adenomas. These items are illustrated by transparencies of photographs and photomicrographs. The major portion of the exhibit is devoted to treatment and illustrates the newest electrothermic methods and surgical techniques.

Experimental Procedures for Inducing Acceptance of Tumor Homografts.

GEORGE D. SNELL, NATHAN KALISS, and ANDREW A. KANDUTSCH, R. B. Jackson Memorial Laboratory, Bar Harbor, Maine.

The main problem of reparative surgery is the hostile reaction set up in the recipient against grafted tissues from a foreign donor. The demonstration shows successful experimental methods used in mice to abrogate their normal resistance to tumor homografts. These methods employ prior injection into the prospective host of suitable tissue preparations or antiserums to the tissues. The main lines of investigation directed toward elucidating the biological mechanisms underlying the induced acceptance of tumor homografts are demonstrated.

Megaloureter.

ORVAR SWENSON, JAMES M. BATY, and JOHN H. FISHER, Boston Floating Hospital for Infants and Children, Boston.

There are several causes of megaloureter. The diagnostic techniques required to separate these patients into their proper categories are displayed and the treatment of the various types illustrated.

Surgery of the Gallbladder and Bile Ducts.

JOHN L. MADDEN, WILLIAM J. MCCANN, and JOHN M. LORF JR., St. Clare's Hospital, New York.

In the belief that the internal splint supports or stents are foreign bodies that produce an undesirable tissue reaction, the necessity of their continued use in reconstructive surgery of the common duct is questioned. The exhibit demonstrates the technique and incidence of exploration of the common duct and the results of both a clinical and an experimental study of the effectiveness of primary reconstruction of the common duct without stent supports. The results of this study question the necessity of stents or prolonged catheter drainage in reconstruction of the common duct.

Congenital Dermal Sinus Tracts.

Franc D. Ingraham, the Children's Hospital, Boston.

The exhibit includes illustrations of intracranial extensions and intraspinal extensions of congenital dermal sinus tracts with pathology and histology. Photographs of patients, x-rays, operative findings, and specimens are shown.

Factors in the Pathogenesis of Acute Pancreatitis—An Experimental Study.

M. A. Block, L. S. Fallis, and R. W. Hansen, Henry Ford Hospital, Detroit.

Acute pancreatitis is divided into two major types as seen clinically: (1) the acute edematous pancreatitis and (2) hemorrhagic pancreatitis with pancreatic necrosis. Our experimental studies on rats and dogs indicate that the acute edematous form can be produced by obstruction of the pancreatic ducts whether or not a common channel with the common bile duct is present. The degree of pancreatic necrosis is not great. Hemorrhagic pancreatitis can be produced by occlusion of the vascular supply of the pancreas whether or not there is concomitant occlusion of the pancreatic ducts. Fat necrosis is most marked when occlusion of the pancreatic ducts is present. Illustrations are used as evidence to support these conclusions, and the experimental findings are correlated with clinical observations. Other factors, considered secondary in significance, are also enumerated.

Intravenous Cholangiography in Clinical Surgery.

Robert E. Wise and Kenneth W. Warren, Lahey Clinic, Boston.

The exhibit shows the results of over 400 injections of cholografin with particular reference to the concept of partial obstruction of the common bile duct due to calculi, fibrosis of the sphincter of Oddi, or stricture or other cause. Emphasis is placed on the criteria for diagnosis of partial obstruction of the common bile duct and the results of surgical explorations and treatment thereof.

Hypoparathyroidism.

E. E. Mason, R. T. Soper, and J. A. Buckwalter, State University of Iowa College of Medicine, Iowa City.

This exhibit is based upon a review of the course of 50 patients with postoperative hypoparathyroidism, 2 patients with pseudohypoparathyroidism, and one with idiopathic hypoparathyroidism. A brief review of the anatomy, embryology, physiology, histology, and pertinent historical data is presented in the form of charts, diagrams, and drawings. Diagnosis, laboratory methods employed, and the course of the disorder in these patients is shown. The action of parathormone, AT-10, and a vitamin D-high-calcium regimen is presented diagrammatically and with suitable representative diagrammed case histories. Emphasis is placed upon the cataracts, neurological, and other long-term sequelas developed by poorly controlled patients, with follow-ups extending more than 30 years. Finally a practical method of management is suggested, the role of the patient and his physician being suggested.

Surgical Treatment of Obliterative Arterial Disease and Arterial Aneurysm.

Charles A. Hufnagel and Pierre J. Rabil, Georgetown University Hospital, Washington, D. C.

The various methods for arterial reconstruction of major arterial trunks are shown by means of transparencies, together with illustrative cases of typical types of arterial obstruction and location of aneurysms from clinical cases. The methods of restoring arterial continuity with use of flexible plastic prosthesis, homografts, and heterografts, are shown as applied to the various lesions. A summary of the clinical results is given.

Usefulness of Chlorpromazine in a Variety of Clinical Problems.

Charles E. Friedgood, State University of New York College of Medicine, Brooklyn, N. Y.

The exhibit summarizes experience with chlorpromazine in more than 400 patients, with particular emphasis on the use of the drug, alone and with local and general anesthetics, in minor surgery. It includes results obtained in using chlorpromazine: (1) to control intractable hiccoughs, (2) to control persistent nausea and vomiting, (3) to relieve pain inadequately relieved by narcotics alone, and (4) to produce hypothermia. Charts, tables, photographs, and case histories show the results obtained.

Rheumatoid Arthritis.

Dwight C. Ensign and John W. Sigler, Henry Ford Hospital, Detroit, and Donald F. Hill and W. Paul Holbrook, Tucson, Ariz.

The importance of early and accurate diagnosis of rheumatoid arthritis is emphasized as a basis for adequate therapy. The salient features of diagnosis and differential diagnosis are presented. Photographs and roentgenograms depict characteristic features of the various stages of the disease. A comprehensive program of therapy is outlined, including the education of the patient in the nature of his disease, the use of general therapeutic measures of proved value, and the necessity of balanced rest and corrective exercises. Supplemental measures such as gold salts and steroids are presented. Photographs illustrate the usefulness of splints and other rest measures and simple devices to aid in daily activities.

Juvenile Rheumatoid Arthritis.

Robert E. Barkin, Theodore B. Bayles, Theodore A. Potter, and J. Sydney Stillman, Robert Breck Brigham Hospital, Boston.

The exhibit includes a graphic presentation of the life history of rheumatoid arthritis in children, with prognosis and therapy.

Treatment of Rheumatoid Arthritis with Prednisone.

Russell L. Cecil, William H. Kammerer, and Richard H. Freyberg, New York Hospital Arthritis Clinic, New York.

This exhibit consists of charts, graphs, and photographs demonstrating the physiological and striking therapeutic effect of a new steroid hormone in rheumatoid arthritis and other rheumatic diseases. Prednisone is a synthetic steroid that possesses the physiological activity of an adrenocortical hormone. Its antirheumatic effect has been demonstrated to be much superior to that of cortisone or hydrocortisone, and physiological side-effects up to the present time have been minimal. Charts and graphs show the effect of this hormone upon various clinical and laboratory aspects of rheumatic disease, such as blood morphology, sedimentation rate, total eosinophil count, 17-ketosteroid excretion, and blood electrolytes. Photographs of the affected joints will demonstrate the clinical improvement.

Gout and Probenecid.

Richard T. Smith, Benjamin Franklin Clinic, Philadelphia, and William P. Boger, Norristown State Hospital, Norristown, Pa.

Data are presented showing the long-term benefits of the use of probenecid not only in the control of hyperuricemia but also in the direction of lessening the size of established tophi, preventing the formation of new tophi, and the actual healing of certain destructive tophaceous lesions. Roentgenologic evidence of the healing of destructive lesions in the bones of gouty patients is presented. The physiological influences of probenecid in the gouty patient are shown and case reports presented to show the alleviation of the course of chronic gout both in terms of uric acid deposition and in reduction of the number of acute gouty attacks. The use of probenecid is correlated with the use of other medicaments such as colchicine, phenylbutazone, salicylates, and steroids in the management of gout.

The U Wave of the Electrocardiogram.

EUGENE LEPESCHKIN and BORYS SURAWICZ, Bishop De Goesbriand Hospital, Burlington, Vt.

The exhibit on the U wave presents the clinically important results of a symposium held in Burlington in 1954. Tables, charts, diagrams and enlarged copies of electrocardiograms are shown.

Stages of Early Cerebral Palsy Behavior.

LAWRENCE J. LINCK and JAYNE SHOVER, National Society for Crippled Children and Adults, Inc., Chicago, and ERIC DENHOFF and RAYMOND H. HOLDEN, Crippled Children and Adults of Rhode Island, Inc., Providence, R. I.

Five stages of early cerebral palsy development are described, and therapeutic principles and methods are correlated. Based on these principles, simple office procedures can be prescribed in preparation for preschool experiences.

Rehabilitation of the Arteriosclerotic Amputee.

RICHARD WARREN and JOHN G. BISGROVE, Veterans Administration Hospital, West Roxbury, Mass.

The exhibit includes (1) an outline of the duties of doctors and others in rehabilitation of the patients; (2) photographs of a patient with an above-knee amputation at various stages of his convalescence illustrating the important points in management; (3) samples of artificial limbs; and (4) patients who will be in the booth to give firsthand demonstrations.

Hydrotherapeutic Tanks—New Design All Purpose Tank.

RALPH E. WORDEN and JAMES A. PATTERSON, Children's Hospital, Columbus, Ohio.

A new design in the hydrotherapeutic and recreational tank is shown in scale-model form. It can be made of steel or stainless steel. Specifications, cost, and technical problems of installation are included. The tank has three compartments; over-all dimensions are 12 by 24 ft., depth from 2 ft. to 4.5 ft. The three tanks have separate temperature control, separate water inlet and outlet, and a complete filtration unit that is included in the model. The technique of temperature control and water circulation and filtration will be demonstrated. New types of hydrotherapeutic techniques made possible will be demonstrated.

Low Back Pain.

GEORGE S. HACKETT, Canton, Ohio.

The exhibit shows an enlarged plastic lumbar and pelvic skeleton with ligaments, trigger points, needles for diagnosis and treatment, and referred pain areas in groin, buttock, and extremities that have been identified from 3,000 injections. Photostats of animal experiments over a three-year period reveal a permanent increase of bone and fibrous tissue by proliferation, which explains the clinical results of 82% of cures in 528 cases in the past 16 years. Charts of statistics and methods are presented.

The Rehabilitation Center: Its Role in Recovery.

W. SCOTT ALLAN, Liberty Mutual Insurance Company, Boston.

The exhibit demonstrates the role of the rehabilitation center in the community program and particularly the importance of its application to industrial cases. The rehabilitation center acts as a supplement to the care received from the attending physician and bridges the gap between hospital and return to work with an individualized program directed at maximum recovery of function and adjustment to physical handicap. A coordinated program of therapy, testing, and counseling, all under medical supervision, provides an effective method of reducing loss in industrial accidents. As a working tool the center becomes an integral part of the community medical and health services interested in the restoration of the individual to an effective physical, social, and economic whole.

Biochemical and Nutritional Effects of Lysine-Reinforced Infant Diets.

ANTHONY A. ALBANESE, REGINALD A. HIGGONS, GERTRUDE M. HYDE, and LOUISE ORTO, St. Luke's Hospital, New York, and St. Luke's Convalescent Hospital, Greenwich, Conn.

Established data on amino acid infant requirements indicate that optional growth and nutrition might be achieved when the dietary provides a lysine tryptophane (L/T) ratio of 6.3. Since the L/T ratios of most foods employed for infant feeding, with the exception of some meat products, are lower than the growth L/T, it was felt that the nutrition of infants, especially those with poor appetites, might be improved by lysine supplementation of the diet. Objective measurements on 35 infants showed that marked positive weight response and nitrogen retention, as well as elevations in plasma proteins and hemoglobin values, were associated with lysine additions to the diet of most infants.

Radioisotopes in the Study of Blood Cell Survival and Blood Volume.

EDMUND W. CAMPBELL, WILLIAM DAMESHEK, MARTIN VERLOOP, and WALTER J. SMALL, New England Center Hospital, Boston.

Demonstration of the methods of tagging blood cells in humans and how the results obtained are interpreted is presented. The technique of measuring red blood cell survival is demonstrated as measured by the radioactive sodium chromate technique. Normal results are compared with those of hemolytic anemia. A technique for evaluating platelet survival is compared with that found in hematological disorders such as leukemia, idiopathic, thrombocytopenic purpura, and polycythemia vera. Determination of blood volume as measured by the radioactive chromic chloride tagging technique is presented. Values obtained in the normal and abnormal states (e. g., polycythemia vera) are compared.

Modern Medical Pitchmen.

OLIVER FIELD, Bureau of Investigation, American Medical Association, Chicago.

This exhibit exposes contemporary quacks and faddists, comparing them to the old-time medicine man who operated from the rear of his wagon. The essentials of the method of operation of each of those mentioned are revealed, together with a brief account of any federal or state regulatory action against the principals.

Medical Aspects of Sport Diving.

ROBERT D. WORKMAN, Experimental Diving Unit, U. S. Naval Gun Factory, Washington, D. C.

The exhibit presents the major types of diving accident that may now confront practicing physicians in many areas. It graphically portrays the etiology and usual circumstances of these accidents, their proper management, and the physician's role in the prevention of such accidents.

Three Centuries of New England Medicine.

EVERETT R. SPENCER JR., Boston Medical Library, Boston.

The exhibit illustrates the growth and development of medicine in New England from the time of Samuel Fuller, the Mayflower physician, to the present, by means of books, letters, photographs, papers, and records now contained in the Boston Medical Library. Seven separate periods are shown as follows: (1) the Colonial Period (1620-1700); (2) the 18th century to 1775; (3) the American Revolution and its aftermath, with the formation of the Massachusetts Medical Society and the development of the Harvard Medical School; (4) the 19th century to 1846; (5) ether anesthesia; (6) medicine in the last half of the Century; and (7) the modern period from 1900 to 1955. A brief printed outline of the highlights of the exhibit will be available.

Medical Practice Facilities.

GEORGE W. COOLEY, Council on Medical Service, American Medical Association, Chicago.

Pictures and descriptive material show various factors to consider in the building or remodeling of physician's office facilities and include various office and equipment arrangements.

The Wood Light—A Diagnostic Tool.

F. Ronchese, Boston University School of Medicine, Boston.

Black and white and color enlargements of dermatoses shown side by side, one taken with ordinary light, the other with the Wood light as the only source of illumination, demonstrate the value of the examination of the skin and mucous membranes under the Wood light, especially for conditions such as ringworm of the scalp, tinea versicolor, vitiligo, psoriasis, atabrine intake, avitaminosis B, external applications, and advanced ulcerated epidermoid carcinoma.

Radiological Diagnosis of Hiatus Hernia.

Leslie K. Sycamore, Mary Hitchcock Memorial Hospital, Hanover, N. H.

Diagnosis of hiatus hernia may present a difficult radiological problem. The exhibit indicates fundamental considerations of anatomy and physiology and illustrates various types of hernia and points of differential diagnosis.

Microanatomy of the Epidermis and Its Appendages.

George Hambrick and Harvey Blank, Columbia University Medical Center, New York.

The exhibit consists of photomicrographs and drawings of recent observations of skin structures. With the aid of collagenase and other chemicals, the pilosebaceous and sweat duct structures have been prepared intact and examined in whole mounts as well as in vertical sections. Various aspects of these structures are illustrated as seen with histochemical techniques and with various types of microscopy.

A Portable Blood Dialyzer: First Trials of Clinical Model 1954-1955.

Arthur E. MacNeill and John E. Doyle, University of Buffalo School of Medicine, Buffalo.

The complete portable clinical blood dialyzing equipment now under clinical trial will be exhibited. Clinical experiences with the MacNeill Mark XI, a blood dialyzer, will be presented by chart, diagram, and photographs of patients under treatment. The Mark XI, a blood dialyzer, is approximately 2 by 3 by 24 in. (5 by 7 by 70 cm.) in size and with all associated equipment can be packed into a portable container 10 in. in diameter and 24 in. long. The ready portability of equipment and its very small size enables treatment of a patient in an ordinary hospital room. Details of this will be exhibited. Essential auxiliaries, such as blood vessel cannulas, simple flow meters, and portable dialysis fluid containers will be exhibited also.

Roentgen Abnormalities of the Large and Small Intestine Associated with Prolonged Cathartic Ingestion.

Norman Heilbrun and Charles Bernstein, University of Buffalo School of Medicine, Buffalo.

In a series of patients, each of whom had ingested irritant cathartics daily for at least 20 years, original film studies are presented revealing the stages of development and severity of the entercolitis-like changes encountered in the large and small intestine. The significance of the absence of a clinical history of diarrhea, crampy or painful bowel movements, and melena is emphasized, particularly in the differential diagnosis from ulcerative colitis and the so-called irritable colon. A theoretical basis for the roentgen findings and the relationships to the types of cathartics ingested are considered.

Ragweed Control: What Can and What Cannot Be Done.

Oren C. Durham, Abbott Laboratories, North Chicago, Ill., and Bernard B. Siegel and Matthew Walzer, Jewish Hospital of Brooklyn, Brooklyn, N. Y.

Ragweed control means ragweed pollen control to the physician. With the advent of selective chemical herbicides a steadily increasing interest is being manifested by the public and by public health and sanitary engineers in ragweed eradication. Owners of health resorts and would-be health resorts are particularly interested. Roadside spraying with 2-4D is being fostered by chemical manufacturers and militant lay organizations.

Female Sterility.

Frederick H. Falls and Charlotte S. Holt, University of Illinois College of Medicine and Illinois State Department of Public Health, Chicago.

The exhibit consists of charts, drawings, medical sculptures, and plastic carvings illustrating the etiology, diagnosis, and treatment of the various phases of human sterility problems. The sculptures are to scale, and actual instruments are used to add realism to the visual educational presentation. The male factors are depicted as would be considered by the obstetrician in his contact with a patient from the laboratory standpoint.

Man's Assumption of an Erect Posture: Influence on Unengagement of Fetal Head.

Joshua William Davies and Elise Renning, St. Luke's Hospital, New York.

This exhibit is an attempt to show that the pelvis did not rotate as man assumed the erect posture. The body of the pubic bone therefore is horizontal in the erect posture as it is in the quadruped. The long bore of the abdominal cavity and the bore of the pelvis are at right angles to each other. Before the onset of labor the entire fetus is contained within the abdominal cavity. It does not pass directly into the pelvic cavity with the onset of labor but must negotiate the lumbosacral angulation of 90 degrees. The exhibit suggests aggressive means whereby an unengaged fetal head may be assisted to enter the pelvic inlet. Its main value is with engagement of the after-coming head in breech presentation.

A New Frontier in Private Practice.

A. Clair Siddall, Oberlin, Ohio.

Attention to individual preventive medicine constitutes a new frontier in private practice. A report is given of an 11-year investigation in which presumably well women were given semiannual examinations, with the focus of interest on the early detection of cancer. Three thousand fifteen examinations have been made on 1,428 women, and 20 cancers have been found, along with 540 benign lesions. Problems of nutrition, work, recreation, rest, marital relations, and minor psychiatric disturbances were considered and treated, thus carrying out individual preventive medicine in the private practice of gynecology.

Current Practical Gynecology.

Walter J. Reich and Mitchell J. Nechtow, Chicago Medical School, Cook County Hospital, and Cook County Graduate School of Medicine, Chicago.

This exhibit deals with problems as they arise in everyday practice of gynecology, be they in general practice or in a specialty. It also deals with the diagnosis, differential diagnosis, and management of conditions in children (pediatric), in adolescents or teen-agers, in childbearing women, in geriatric patients, and in patients with psychosomatic problems. Acute and chronic gynecologic conditions requiring surgery are discussed in differential diagnosis.

Foreign Service Provides a Worldwide Clinical Laboratory.

H. van Zile Hyde and John J. Hanlon, Division of International Health, U. S. Department of Health, Education, and Welfare, Public Health Service, and Public Health Division of International Cooperation Administration, Washington, D. C.

The exhibit is a replica of a clinical laboratory in the tropical areas. On the work bench are pathological materials and data encountered in the physical and laboratory diagnoses of clinical and subclinical cases of malaria, schistosomiasis, trypanosomiasis, smallpox, leprosy, filariasis, enteric infections (amebiasis, bacillary dysentery, and infectious hepatitis) and an unknown Bolivian virus infection.

REPORTS OF OFFICERS

REPORT OF THE SECRETARY

To the Members of the House of Delegates of the American Medical Association:

The following annual report of the Secretary is respectfully submitted:

Membership

The trend toward increased membership in the American Medical Association continued during the year ending June 30, 1955. The income from membership dues for the first six months of 1955 was $3,014,255.00, which was an increase of $132,040.00 over the same period for 1954. The number of physicians holding membership in the Association increased by 6,567 during the year ending June 30, 1955, as compared with the same period ending June 30, 1954. A breakdown of the membership records as of June 30, 1955, indicates the following:

Active Paid Members	123,462
Active Members (dues unpaid for 1955)	7,649
Active Members exempted from payment of dues	11,167
Associate Members	4,821
Service Members	8,402
Affiliate Members	282
Honorary Members	95
Total	155,878

The total number of members at the present time exceeds by several thousand the number reported in any previous year, even including the years when there were no membership dues.

The table below shows physician members of state and territorial medical associations and the American Medical Association. Comparative figures are given as of June 30, for 1955 and 1954:

	Active				
	Dues Paying	Exempt	Associate	Total 1955	Total 1954
Alabama	1,352	274	..	1,626	1,563
Arizona	721	34	42	797	743
Arkansas	934	168	..	1,102	1,054
California	12,826	588	713	14,127	13,051
Colorado	1,526	48	409	1,983	1,821

Service Members				8,402	8,276
Affiliate Members				282	268
Honorary Members				95	95
Total				155,878	149,311

As of June 30 there were approximately 7,649 physicians whose American Medical Association membership status for the year 1955 had not yet been established through their constituent medical associations. A list of these physicians has been forwarded for review to the secretary of each constituent society, and direct notices to the physician are being mailed during September. If the physician's eligibility for continued membership is not established for the year 1955, the physician will be dropped from membership in the American Medical Association under the provisions of Chapter III, Section 5 of the Constitution and Bylaws. A physician cannot be reinstated to membership until his dues delinquency for the year in which he was dropped from membership is cleared through his constituent medical society.

The conversion of the manual operation of the membership records to an IBM key punched card system was completed during the last fiscal year. The increased efficiency and flexibility of this new system has made it possible to mail the Membership Pocket Card to the physician within a reasonable time after membership status has been established with the Membership Department by the constituent society. Also, new American Medical Association members now receive the first copy, and back issues, of the publication they have chosen as a benefit of paid membership immediately after dues payment is recorded.

The secretaries of constituent and component medical associations have cooperated whole-heartedly, and many of them have been instrumental in revising their local membership regulations to conform with the standard pattern of membership set by the Association's Constitution and Bylaws.

Actions of the House of Delegates at 1955 Annual Meeting

In a special letter to the secretaries of the constituent state and territorial medical associations, the Secretary called the attention of these executives, for such reference and implementation as might be indicated, to actions of the House of Delegates at its Atlantic City session in June, as follows:

Supplementary report of the Board of Trustees "I" on Guides for Grievance or Mediation Committees. The action of the House on this report was to urge the constituent and component societies "to lend their support to the study and assist the committee in developing a practical set of guides."

Supplementary report of the Board of Trustees "H" on Civil Defense. In this report the Board of Trustees recommended, and the House approved the recommendation, that "the state and county medical associations be urged to participate aggressively in civil defense programs."

Resolution No. 21 on Automotive Safety. It is asked that you send this resolution to the proper authorities in your state.

Report of the Reference Committee on Medical Military Affairs on Resolution No. 55 on Civil Defense, in which each constituent association is urged "to develop a practical program for carrying out its medical civil defense responsibilities."

Several replies were received, and it is evident that the constituent associations are ready and willing to cooperate in every way possible with the expressed wishes of the House of Delegates.

Copies of Resolution No. 71 on Draft of Medical Students were sent, through the Washington Office, to the President of the United States and to all members of both houses of Congress. As a result of this, it was possible to publish the following statement in THE JOURNAL.

> After protest by the American Medical Association House of Delegates against the drafting of students who temporarily interrupt their medical education to become science teachers, the National Selective Service System is altering its policy and advising that these students now be deferred. The House of Delegates at its June meeting pointed out that schools of medicine are dependent on the services of students who interrupt their junior or senior years to become assistants in physiology, pathology, anatomy, physiological chemistry, bacteriology, or other preclinical departments. The resolution declared in part: "The training of the medical students of today and in the years which lie ahead will be seroiusly jeopardized if the present policy of Selective Service with regard to drafting of medical students who drop out of schools to become assistants and teachers of preclinical subjects is permitted to continue." At the same time the House of Delegates instructed that a copy of the resolution be sent to all members of Congress.
>
> On July 13 Selective Service amended a previous bulletin to call attention to the critical need for certain science teachers. At that time it declared, "Secondary schools are particularly hard-pressed to find qualified teachers of mathematics and the physical and biological sciences. Local boards are requested to give particularly careful consideration to the occupational deferment of any registrant who [becomes] . . . a teacher in any of the fields of physical and biological science, mathematics, medicine, or dentistry." Five days later Selective Service announced specifically that the bulletin "has been revised to include medical and dental schools."

Resolution No. 27 on Presumption of Service-Connected Disabilities was sent, also through the Washington Office, to the Administrator of Veterans' Affairs and the chairmen of the committees of the House and Senate having jurisdiction over veterans' affairs. This resolution placed the American Medical Association in a position of opposition to the establishment of "service connection by presumption" for disability developing after military service and, in addition, urged the establishment of service connection for disability on an individual evaluation based on firm medical evidence.

The House of Delegates approved a recommendation submitted by the Board of Trustees that the Section on Physical Medicine and Rehabilitation be renamed the Section on Physical Medicine, and it also adopted a resolution (No. 74) that changed the name of the Section on Dermatology and Syphilology to Section on Dermatology. However, Section 1, Chapter VII of the Bylaws, which lists the names of the sections of the Scientific Assembly, was not amended. The Secretary has informed the Council on Constitution and Bylaws concerning this omission and understands that that Council will present an amendment for approval by the House at this session.

Field Activity

The Secretary and Assistant Secretary during the past year have been even more active than previously in the number of medical meetings to which they have traveled and before which they have spoken. The number of meetings of committees, councils, commissions, etc., which they have had to attend also has increased, so that a great deal of their time is spent in this type of service to the Association. However, they attempt to coordinate their absences from Headquarters so that neither is away at the same time. It is regretted that occasionally this is not possible to accomplish.

Appreciation

The Secretary offers an expression of grateful appreciation to the members of the House of Delegates, the officers and members of official bodies of the Association, officials of state and county medical societies, and many individual members for their consideration and aid. He also wishes to express to his associates of the administrative staff and to other loyal and efficient personnel his sincere appreciation.

Respectfully submitted,

GEORGE F. LULL, Secretary.

REPORT OF THE BOARD OF TRUSTEES

To the Members of the House of Delegates of the American Medical Association:

The following annual report of the Board of Trustees is respectfully submitted.

Report on Matters Referred by House of Delegates

Geriatrics.—In response to the directive of the House of Delegates that a Committee on Geriatrics be appointed to function under the Council on Medical Service, members of the Committee are now being selected by the Council, with the approval of the Board. At the present time no consultants will be named; however, if in the future the Committee deems consultants necessary they will be added. The broad objectives of the Committee will be to outline basic problems of geriatrics to be attacked, and methods for approaching these basic problems.

Resolution No. 23 on Reimbursement for Collecting American Medical Association Dues.—The Board of Trustees carefully considered Resolution No. 23, introduced into the House of Delegates in Atlantic City by Dr. Gerald D. Dorman on behalf of the New York delegation, which would direct the full reimbursement of constituent and component associations and societies annually for their expenses in collecting and transmitting American Medical Association dues for the preceding calendar year.

The Board is cognizant of the difficulties experienced in New York relative to the collection of dues. It does not feel, however, that increased reimbursement of constituent state and component county medical societies is the answer in this regard. Most of the state associations send out one bill for both the national and state dues, thereby eliminating the expense of two mailings. There is, of course, an added burden of bookkeeping, writing checks, and handling correspondence, but it is understood by the Board that the allocation of 1% of the dues collected is ample in most instances to cover these expenses. The recommendation of the Board is, therefore, that no change be made in the policy in effect at the present time.

Resolution No. 49 on Introduction of Committee Reports.—The resolution introduced by Dr. Byron Blaisdell at the Atlantic City meeting of the House of Delegates was carefully considered as to the feasibility of its implementation, i. e., that all committee reports be submitted to the Association sufficiently early to be transmitted to members of the House of Delegates not less than 30 days prior to the meeting at which they are to be introduced and that all reports not so submitted be deferred for introduction until a later meeting of the House unless exception be made by a two-thirds vote of the House.

The Board feels that although the intent of the resolution is sound, it would not be practical to carry out the recommendations contained therein.

Other Resolutions.—All of the other resolutions which were referred to the Board of Trustees by the House have been referred to the appropriate council, committee or department at Headquarters. As soon as reports are received on these matters, they will be transmitted to the House of Delegates.

Distinguished Service Award

The Board of Trustees requests all members of the Association to submit nominations for the recipient of the Distinguished Service Award. It will be appreciated if these nominations are forwarded to the headquarters office by March 1 of each year.

The Journal of the American Medical Association

The activities of THE JOURNAL and of those departments associated with this periodical are, in general, evident with each weekly issue. From time to time innovations are introduced and the more popular or needed sections expanded. The information reported in THE JOURNAL is gathered with the needs and demands of the profession and of the Association and its individual offices in mind. Each year, in fact each season, presents new information on medical problems and as this is gathered it is reported in THE JOURNAL pages. Similarly, as the committees, councils, and bureaus of the Association report on projects in which they are engaged this information becomes available in THE JOURNAL.

The number of scientific articles that are published each year run into the hundreds and the number of other items well into the thousands. Some indication of the extent of activities of the various departments of THE JOURNAL is evident in statistics gathered for Queries and Minor Notes, Medical News, and Medical Literature Abstracts. About 200 inquiries are received each month in the Queries and Minor Notes department of THE JOURNAL. More than 1,000 consultants are on the list used by this department for reference of these questions. During the course of a year, the Medical News department now publishes approximately 3,000 items and about the same number of obituaries. Between three and four hundred pages of THE JOURNAL are used each year for this reporting. The Medical Literature Abstracts department searches more than 1,200 publications for information that it abstracts for THE JOURNAL, and these abstracts make up some 12 to 18 pages in each issue of THE JOURNAL. The abstracts are always prepared with the practitioner in mind.

Specialty Journals

During the period of the past 12 months, changes in the appearance of the specialty journals have been completed. These include a new cover design, an improved format, expanded use of color illustrations, and new editorial features. It has been encouraging to learn that the majority of readers who have reacted through correspondence and personal contact accept the changes enthusiastically. It is the policy to satisfy all subscribers if possible, and efforts will continue to modify, where strong interest is indicated, to meet the tastes of more readers. The cover and page format are flexible enough to permit necessary adjustments.

The specialty journals have been experimenting with new color reproduction processes. Cost of color illustrations has been a block to any extensive use of color. In addition to the regular letter press method, test articles have employed the Polychrome Process, offset, and most recently the Poster-Chrome method. The latter has stirred most interest on the basis of cost and results. Some slight adjustment from standard inks generally used in this process gives promise of true color and quality reproduction. It gives every indication of a wider use of color in the specialty journals.

The detailed reproduction of scientific exhibits and the illustrated articles have been editorial features incorporated into the specialty journals. It is of interest to note that the A. M. A. Archives of Surgery has received the top award of the American Medical Writers' Association for its editorial selection and feature material presentation for the year 1955.

The illustrated article is the basis for "Medicine Illustrated." At present it is being developed to a very high degree of quality for the Archives of Surgery. Intended as a solicited feature, instructions for preparation of an illustrated article are being requested by prospective contributors.

The A. M. A. Archives of Industrial Health will offer its readers, beginning in its October issue, a 16 page section of public health news. This material is being prepared by the United States Public Health Service and will be a regular monthly feature in this journal.

Specialized section papers are being published in the specialty journals in ever-increasing numbers. Important symposiums are also being featured. These new sources of manuscripts, together with the introduction of new features, are providing more than adequate copy for the journals.

During the past 12 months not one issue of the nine specialty journals has been delayed beyond the month it was due. Although there is some consolation in this record, it falls short of the department's desire to publish all journals very early in the publication month, and, even better, late in the month prior to due month. This problem will receive particular attention in the months to come. A workable plan to prepare a standing inventory of articles in type goes into effect immediately.

During the first eight months of 1955 the specialty journals published 944 original articles, 29 progress reports or general reviews, 139 case reports or clinical notes, 9 special articles, 21 scientific exhibits, and 13 editorials, or a total of 1,155 articles. The total of unpublished articles for all specialty journals is 585. It is anticipated that about 600 more papers, including original articles, progress reports, general reviews, case reports, clinical notes, special articles, scientific exhibits and editorials, will be published during the remainder of 1955.

Circulation figures as of Sept. 1, 1955, for all nine specialty journals show a net decrease of 1,130 as compared with the corresponding period in 1954. Specialty journals showing a decrease are as follows: A. M. A. Archives of Internal Medicine, 548; A. M. A. American Journal of Diseases of Children, 195; A. M. A. Archives of Neurology and Psychiatry, 59; A. M. A. Archives of Dermatology, 291; A. M. A. Archives of Otolaryngology, 272; A. M. A. Archives of Ophthalmology, 271; and A. M. A. Archives of Industrial Health, 25. Two specialty journals, A. M. A. Archives of Surgery and A. M. A. Archives of Pathology, had increases in circulation of 513 and 18 respectively. "Take offs" have been greater than "place ons" due to the clearing up of old records. Recent reports have indicated that this trend has been reversed and that for most journals the "place ons," indicating an increase in circulation, are now greater than the "take offs."

SPECIAL PROJECTS

The following titles are under contract with various medical publishers: J. A. M. A. Clinical Abstracts of Diagnosis and Treatment; A. M. A. Scientific Exhibits—1955; J. A. M. A. Queries and Minor Notes.

The trial volume of "J. A. M. A. Clinical Abstracts" has already been published. Originally intended to meet the demand for J. A. M. A. material abroad, it is hoped there will also be a domestic demand. The publication of a second volume depends on the market.

The "A. M. A. Scientific Exhibits—1955" is expected to be published in time for the Boston Clinical Meeting. This volume is a collection of the award winning exhibits shown at the Atlantic City Meeting, plus additional selections to complete a volume of 800 pages. This is intended to be an annual publication.

"J. A. M. A. Queries and Minor Notes" is the future version of "Questions and Answers." It is expected as an early 1956 release.

Agreement has been reached for the publication of a new type of abstract volume utilizing illustrations rather than the conventional descriptive abstract. It will also include a reference feature. The idea will first be developed in the field of surgery. It is anticipated other specialties will lend themselves to similar treatment, thus developing a series of illustrated volumes.

Contracts have been signed for the distribution of back volumes of the Quarterly Cumulative Index Medicus, and for the reprinting of out-of-print volumes. These agreements place the Association in the position of dealing directly only with current volumes.

An effort is being made to bring all American Medical Association publications under a contract especially suited to the circumstances peculiar to Association activity. The Law Department developed the contract. While it is designed to protect the interests of the Association, it has been made purposely flexible to meet also the specific interests of the publisher. When all titles are finally under this contract, there will be uniformity in dealings with all publishers.

Report of Circulation Department

CIRCULATION OF SCIENTIFIC JOURNALS

The circulation of THE JOURNAL of the American Medical Association and the nine specialty journals leveled off during the fiscal year ending June 30, 1955. The average circulation of each publication for the 12 month period ending June 30, 1955, is indicated in the following table:

Average Circulation for Fiscal Year—July 1 Through June 30

	1955
THE JOURNAL	
Membership copies	116,562
Subscriber copies	44,105
Net paid copies	160,667
Advertising, exchange, complimentary, and other free copies	5,378
Total distribution	166,045
Archives of Internal Medicine	
Membership copies	1,991
Subscriber copies	7,100
Net paid copies	9,091
Advertising, exchange, complimentary, and other free copies	848
Total distribution	9,939
American Journal of Diseases of Children	
Membership copies	2,017
Subscriber copies	5,456
Net paid copies	7,473
Advertising, exchange, complimentary, and other free copies	853
Total distribution	8,326
Archives of Neurology and Psychiatry	
Membership copies	981
Subscriber copies	3,501
Net paid copies	4,482
Advertising, exchange, complimentary, and other free copies	724
Total distribution	5,206
Archives of Dermatology	
Membership copies	684
Subscriber copies	4,101
Net paid copies	4,785
Advertising, exchange, complimentary, and other free copies	726
Total distribution	5,511
Archives of Pathology	
Membership copies	481
Subscriber copies	3,144
Net paid copies	3,625
Advertising, exchange, complimentary, and other free copies	629
Total distribution	4,254
Archives of Otolaryngology	
Membership copies	1,382
Subscriber copies	4,168
Net paid copies	5,550
Advertising, exchange, complimentary, and other free copies	702
Total distribution	6,252
Archives of Surgery	
Membership copies	3,167
Subscriber copies	3,463
Net paid copies	6,630
Advertising, exchange, complimentary, and other free copies	702
Total distribution	7,332
Archives of Ophthalmology	
Membership copies	2,441
Subscriber copies	4,493
Net paid copies	6,934
Advertising, exchange, complimentary, and other free copies	778
Total distribution	7,712
Archives of Industrial Health	
Membership copies	126
Subscriber copies	2,654
Net paid copies	2,780
Advertising, exchange, complimentary, and other free copies	555
Total distribution	3,335

Subscribers who are not receiving a publication as a benefit of paid membership are required to pay for their subscription in advance.

Expiration notices are sent out two months in advance of the date of expiration, and all accounts are terminated at expiration, unless the renewal order with payment has been received. This policy has stabilized the circulation of the publications and has simplified and improved the clerical operations involved. It is now possible to conduct a promotion campaign to gain new subscribers for THE JOURNAL as well as for the specialty journals. Several test mailings have already been made and an intensified promotion campaign directed to non-dues-paying members and nonmembers of the American Medical Association and Canadian and foreign physicians will be conducted this fall. Also, special promotion mailings will be directed to graduating medical students and physicians entering active practice next spring.

REGISTRATION AT MEETINGS

The Director of the Department is responsible for the proper registration and admittance of all member physicians and their guests at both the annual and the clinical meetings of the Association.

The registration at the Miami Clinical Meeting and the Atlantic City Annual Meeting is shown in detail below. Economies in the operation of the Registration Bureau have been effected during the past fiscal year. The total cost of registration at the Miami Meeting was $3,644.00, which was a saving of $9,182.00 over the cost of the previous year's Clinical Meeting in St. Louis. The cost of registration at the Altantic City Meeting was $6,793.00, which was a saving of $4,853.00 over the cost of the previous year's Annual Meeting in San Francisco.

Registration, Miami, Nov. 29–Dec. 2, 1954

Physicians	3,253
Residents	136
Interns	43
Students	176
Nurses	306
Technicians	130
Physicians' guests	2,883
Total	6,927
Exhibitors	574
Exhibitors' guests	206
Grand total	7,707

Registration, Atlantic City, June 6-10, 1955

Physicians	11,518
Residents	875
Interns	518
Students	403
Nurses	470
Technicians	248
Physicians' guests	13,368
Total	27,458
Exhibitors	2,504
Exhibitors' guests	1,095
Grand total	31,057

Library

Since the last report of library activities covered the calendar year 1954 and the next, according to a recent action of the Board of Trustees, is to deal with the period from July, 1955, through June, 1956, this review refers only to the first six months of this year.

During this time there occurred a lapse of three months between the resignation of the reference librarian and the arrival of her successor, which handicapped the work in this department. However, a total of almost 1,300 requests was recorded, 965 of them requiring the preparation of package libraries, and a number of others involving the compilation of bibliographies or search of the literature for special information. This total does not include numerous minor inquiries and telephone calls that are received each day.

Of the package libraries mailed to borrowers, 577 were returned promptly, an extension of time was requested for 48, a post card reminder was required for 288 and follow-up letters for 50, but only 2 have not been returned.

Altogether 5,747 individual issues of periodicals were loaned, 2,313 included in package libraries, and 953 borrowed for use by other departments in the headquarters building.

A complete survey of the book collection has been undertaken with the purpose of withdrawing any items that are outdated or little used. The general policy is to eliminate books more than 10 years old unless they are of particular value for the needs of this library or are standard works basic for any collection. At the same time the shelf list and the catalog cards are being checked and revised.

In preparing the index to the first volume of THE JOURNAL, special attention was given to cutting superfluous cross references and duplicate entries and to curtailing of certain sections, with a consequent 25% reduction in the number of pages required for the index.

Quarterly Cumulative Index Medicus

Although no completed volume of the Index appeared during the first six months of this year, the editing of copy for volume 53 (January-June, 1953) was finished in April and the page proof in June. In the meantime editing of the next volume began. The material for volume 55 (January-June, 1954) is all indexed, and it has been possible to continue processing English language journals as soon as they are received.

A plan has been formulated for speeding production of the Index by publishing three volumes in 1956 and the same number in 1957. This will finally bring the Index up to date by 1958. In order to implement the project it has been decided to confine the list of periodicals indexed, at least for the present, to English language journals and those published in the Western European and Latin American countries, with the inclusion of certain titles from the Soviet Union. A few new journals of special interest have been added, but unfortunately many others must by necessity be bypassed.

Standard Nomenclature of Diseases and Operations

Work on the *fifth edition* of *Standard Nomenclature of* Diseases and Operations has progressed rapidly in the past 10 months. The 23 committees appointed by the Editorial Advisory Board on March 7, 1953, work in close collaboration with the editors. Preliminary reports have been submitted by the Ophthalmology, Anesthesia, Dermatology, and Neurology Committees.

The supplement carrying the changes, deletions, and additions, printed in THE JOURNAL, Aug. 14, 1954, has proved very beneficial. The Nomenclature is now being used in 84.8% of the hospitals of the United States and has considerable foreign distribution. In addition, there is a definite trend toward installation of the Nomenclature in a number of doctors' offices and clinics. Approximately 2,520 queries have cleared through the headquarters office since October, 1954. Approximately 33,000 copies of the fourth edition of the Standard Nomenclature of Diseases and Operation were sold up to January, 1955.

An educational exhibit on standard nomenclature explaining the organizational setup was displayed at the American Association of Medical Record Librarians meeting in Detroit in October, 1954, and at the American Medical Association annual meeting in Atlantic City in June, 1955. The exhibit will also be displayed at the American Hospital Association meeting in Atlantic City in September, 1955, and at the American Association of Medical Record Librarians meeting in Chicago in October, 1955.

STANDARD NOMENCLATURE INSTITUTES

In September, 1954, a three day standard nomenclature institute for medical record librarians was taught in Evansville, Ind. In November, 1954, a lecture on standard nomenclature was given before the American Association of Medical Clinics in New Orleans, and the nomenclature was taught at a five day institute for medical record librarians in Los Angeles, the latter institute being sponsored jointly by the American Hospital Association and the American Association of Medical Record Librarians.

The American Medical Association sponsored and conducted three day standard nomenclature institutes in February and May, 1955. The Association-sponsored institutes were tuition-free, and the lectures were designed to accommodate beginners, intermediates, and advanced students. Registration was not restricted to medical record librarians. Office secretaries, medical secretaries, clinic clerks, nurses, statisticians, and medical record librarians registered. Applications for the February institute exceeded 400. One hundred fifty of this group were accepted in February and 100 in May. Due to the fact that it has been necessary to limit registration at these institutes and in order to accommodate prospective students, another standard nomenclature institute will be given in October, 1955, at Association headquarters. Regional standard nomenclature institutes are now under consideration. The nomenclature institute teaching is under the direction of the Associate Editor, Adaline C. Hayden. The anatomy lectures, based on the topographic section of the standard nomenclature, are taught by Dr. Edward T. Thompson, Washington, D. C. Through the above mentioned mediums, approximately 600 students have received instructions in the use of the nomenclature. The Editorial Advisory Board for the fifth edition appointed by the Board of Trustees is composed of Drs. George Baehr, *Chairman, New York;* Edwin L. Crosby and Austin Smith, Chicago; Selwyn D. Collins and Edward T. Thompson, Washington, D. C.; Richard J. Plunkett, Editor, Chicago; and Adaline C. Hayden, C.R.L., Associate Editor, Chicago.

Today's Health

During the period covered by this report, July 1, 1954, to June 30, 1955, a number of rather drastic changes were made within the operational framework of *Today's Health.* These changes were designed to put the magazine on a firm financial basis and, at the same time, improve *Today's Health* from the standpoint of appearance, content, and salability.

Early in the fall of 1954, the Board of Trustees of the American Medical Association created the position and approved the appointment of a Managing Publisher. This became an accomplished fact at the Miami Clinical Meeting the first week of December, 1954. The assignment given the Managing Publisher was to make *Today's Health* a profitable operation and erase the deficit under which the magazine has been operating in recent years. To accomplish this, sound budget control procedures have been developed and close coordination has been established between departments.

EDITORIAL DEPARTMENT

By action of the Board of Trustees at the 1954 Clinical Meeting, Dr. W. W. Bauer was made Chief Editor of *Today's Health,* and a five man Editorial Advisory Board was appointed. Members of this Board are Drs. Julian P. Price, Walter E. Vest, George F. Lull, and Austin Smith, and Mr. Leo Brown. Dr. W. W. Bauer is Chairman.

Following approval of the 1955 *Today's Health* Editorial Department budget, two things were immediately done. A firm of outside consultants, the Eastman Research Organization, was retained, after a lapse of five years, and a seasoned article editor was hired. The Eastman group made its first study on the January, 1955, issue and, in part, reported: "We find no evidence that the magazine has slipped and some indication that it has improved. There is considerable praise. There are some things susceptible to improvement, as of course there always will be, and we point these out." Furthermore, the study indicated that *Today's Health* is attracting more readers under the age of forty, that home subscribers are passing along copies to more acquaintances than ever before, that many more subscriptions are being renewed, and that *Today's Health* is read better than are many topnotch business publications. Continuing study of the magazine, with periodic reader surveys, is of immense practical help to those planning and shaping its editorial content. Except to them, the Eastman recommendations may seem to deal largely with minutiae, but reader reaction has demonstrated that it is of a myriad of small improvements that progress is made.

Great impetus has been given to these improvements by the employment of a seasoned article editor. This is gradually enabling the Editorial Department to work further and further ahead of deadlines, reducing the chance of error, and to give the business departments an earlier and better idea of what is going to appear in future issues—for both advertising and circulation promotion—and probably will soon make a minor but definite cut possible in printing costs.

Long-range planning has been made more effective and its results more readily available for the Advertising and Circulation Departments. This has been practiced in some degree for eight years, but its present development could hardly have been reached without the improvement in editorial procedure and by the employment of an article editor. With one major gap, there is now, for the first time in the history of the magazine, a basic framework for an efficient editorial operation. The gap is the lack of a Production Department, but the development of that department has been approved by the Board of Trustees and it will be in operation by the first of 1956.

One editor has said that *Today's Health* is "the most quoted magazine in the world." Its articles are regularly reprinted or "digested" by publications in the United States, England, and more remote parts of the world and by the information services of the U. S. Department of State. A striking sign of progress is a decision of the Dell Publishing Company to publish a collection of *Today's Health* articles in book form. These books will be given national distribution.

CIRCULATION

The circulation of *Today's Health* made decided gains in the last half of 1954, due to Operation MD-DDS of the medical society auxiliaries. These gains continued and the average net paid circulation for the first six months of 1955 was 361,598, thus maintaining the highest circulation figure ever established for the magazine. The renewal percentage on subscriptions reflects a wider acceptance of the magazine and a healthy growth of interest by the laity. Also, the *Today's Health* renewal percentage compares favorably with national consumer magazines such as *Look, Life, Colliers,* and *Newsweek,* which are happy to approach a renewal percentage of 50%.

The number of copies of *Today's Health* going into the offices of physicians and dentists has risen from 15.4% in May, 1954, to 26.7% in May, 1955, and is the result of the Woman's Auxiliary Subscription Project. Six to eight month trial subscriptions were placed in many reception rooms, and the *Today's Health* committees of the local medical society auxiliaries contacted each physician and dentist for a long-term renewal. Where this did not result in a renewal subscription, two direct-mail efforts were sent from the *Today's Health* office to follow up the expirations. The wide distribution of the magazine in reception rooms will help to increase the percentage of returns on fall and winter direct-mail promotion efforts to the laity. It is planned to mail sufficient promotion efforts to the laity during the next fiscal year to bring the paid circulation up to approximately 450,000 by June 30, 1956. This sizeable circulation increase will be of great advantage to the Advertising Department in securing new advertising accounts.

In addition to the 23,910 schools and teachers who regularly subscribe to the magazine, 73 high schools and colleges used *Today's Health* in the classroom under the magazine's Group Study Plan during the 1954-1955 school year. An average of 2,885 copies per month were used in these schools, which were supplied with a monthly list of discussion topic questions and answers based on each issue. A total of 28,846 copies were used by the students during the last school year, and, as each copy is normally used by more than one class, the magazine actually reaches a very large audience of students.

Today's Health has been displayed at eight national conventions this year, and sample copies, promotion circulars, and subscription forms have been distributed to professional and educational leaders. The Woman's Auxiliary has set a goal of 63,000 new and renewal subscriptions for its current project ending May 31, 1956, and there is every reason to believe that this quota will be reached. Special promotion material, order forms, and project prizes will be used to stimulate the local auxiliaries' activity.

Promotion efforts are being continued to increase the use of *Today's Health* by industrial and business firms. Group subscriptions ranging from 10 copies to 1,200 copies have been received during the past year, and it is expected that the wider recognition of the health education value of the magazine by industrial physicians and industrial and business leaders will stimulate this project. Also, the nation's leading railroads, airlines, and steamship lines are beginning to place the magazine in lounges of their passenger carriers, and this will bring *Today's Health* to the attention of a greater number of business, professional, and industrial leaders than ever before.

ADVERTISING

During the period covered by this report, gross advertising income was $231,667.57, an average of $19,305.63 per issue. Fifty-one new advertising accounts were established during this 12 month period, and, as of June 30, 1955, there were 176 active accounts using *Today's Health* as an advertising medium.

Direct-mail advertising promotion efforts were continued on a consistent basis during the latter part of 1954 and the early part of 1955. Tradepaper advertising was discontinued in January, 1955, in an effort to conserve promotion dollars.

MECHANICAL PRODUCTION

There are no significant production facts to report concerning the last six months of 1954, but a number of things occurred between Jan. 1 and June 30, 1955. Perhaps the most drastic move was the decision to reduce the size of the magazine from 72 pages plus cover to 64 pages plus cover. The elimination of eight pages accomplished two things: It immediately brought the editorial-advertising ratio into better balance and at the same time reduced manufacturing costs by an estimated $53,000. Fortunately, this move has not affected the variety of fare offered from an editorial standpoint. If anything, it has sharpened quality in that now only the best material can win the competition for the limited space.

All editorial color appearing in *Today's Health* is derived from special inks worked out exclusively for *Today's Health* by its Art Director and McCall Corporation ink experts. This is a practice followed by a number of other national magazines, and it has already helped improve the eye-appeal of the magazine.

During the last six months of 1954 a total of 1,980,601 copies were printed. For the first six months of 1955, it had been planned to print 2,100,000 copies for a budgeted manufacturing cost of $225,757. The actual expenses for the first six months of 1955 totaled $225,132 and 2,254,650 copies were manufactured.

Through the Magazine Publisher's Association, *Today's Health* will soon be in position to secure comparative manufacturing cost figures from other leading magazine publishers, and there is every reason to believe that by closely watching all phases of the manufacturing operation over-all costs can be further reduced. The development of the *Today's Health* Production Department and the employment of a Production Coordinator will be of considerable help in this regard.

While *Today's Health* will not be "in the black" at the end of 1955 definite progress is being made. A basically sound organization has been established, and with the continued fine cooperation from staff members it is felt that *Today's Health* will continue to make a real contribution to the American Medical Association and to the general public.

Report of Directory-Biographical Department

STATUS AS UNIT OF DEPARTMENT OF RECORDS AND CIRCULATION

For the three years prior to Jan. 1, 1955, the Directory-Biographical Department, together with the Membership-Circulation Department, functioned as the Department of Records and Circulation. These units had been integrated in January, 1952, under a single director in order to streamline overlapping clerical routines and to make more efficient use of established techniques and facilities during the transition period immediately following the sweeping changes made in the membership, structure of the Association. By the autumn of 1954 the membership records had been brought up to a current basis, making it feasible to begin compilation of a new edition of the American Medical Directory. An edition of the Directory had been tentatively scheduled for publication in 1952, but plans for it had to be postponed because it was not possible at that time to obtain an accurate list of members of the Association.

From January, 1952, to January, 1955, personnel from both units of the Department centered all efforts on the establishment of an accurate membership record. An attractive new membership card, incorporating the official emblem of the Association, was designed and adapted for each of the five types of membership—Active, Service, Associate, Affiliate, and Honorary. Tangible evidence of the results accomplished can be seen in the following comparison of the numbers of members in the various categories at the end of 1952, 1953, and 1954 respectively. The figures for 1952 are approximate and incomplete.

	1952	1953	1954
Active members (including active members excused from payment of dues)	126,000	133,811	138,511
Associate members	5,000	4,534	4,778
Service members	9,000	8,078	9,362
Affiliate members	?	270	268
Honorary members	?	?	95
Total membership at end of year..	140,000	146,723	153,014

Status in 1955

With an accurate record of membership available for 1954, the Department of Records and Circulation was dissolved as of Jan. 1, 1955, and the Directory-Biographical Department again established as a separate unit. The Department, however, has continued to maintain, so that the information can be published in the Directory, a record of those physicians who hold membership in their constituent association but do not hold membership in the American Medical Association. A special symbol will appear in the biographical data of these physicians, estimated to number about 17,000 in the United States and its dependencies.

After the 18th edition of the American Medical Directory had been published in 1950, the type was left standing. Two revisions had been made, one late in 1951 and the other during the early part of 1952, before it became apparent that it would not be feasible to issue a new edition in 1952. Beginning in September, 1954, however, after the physicians' 1954 membership status had been posted on the Directory records, the actual work of compiling the new, 19th edition began with the mailing of information cards to all physicians. During the period from Sept. 8 through Nov. 26, a card was sent to each physician in the United States and its dependencies and Canada and to American physicians in foreign countries. The card, prepared in cooperation with the Bureau of Medical Economic Research, requested information on office and residence addresses, specialty, and type of practice for publication in the Directory and also requested information—not for publication—on the source of income and the physician's major type of practice. A disappointingly small proportion of information cards was returned. Out of 246,236 mailed, only 74,515 had been returned by the end of January, 1955. During February and March, therefore, a second request for information was mailed to 132,625 physicians who had not returned the first card and who had not been recently reported as serving a hospital appointment. Because a large number of addresses still had not been verified by June, efforts had to be made to check current telephone directories, rosters of the constituent associations, and state registers of licensed physicians. If the address could not be verified in this manner or if a possible change of address seemed to be indicated, a third letter was sent to the physician. The Directory Information card was not enclosed with the letter, as it was felt that possibly physicians had not returned the first two cards sent to them because they did not wish to supply the information requested on the source of income, which data had been intended for the statistical use of the Bureau of Medical Economic Research. The third letter, asking simply for the physician's current address and specialty or type of practice, has been sent during July and August, 1955, to more than 13,000 physicians. Proof cards have also been sent to hospitals and sanatoriums to verify their listings in the new edition.

As of Sept. 1, 1955, most sections of the Directory were about to go through a final revision. If the work proceeds on a normal schedule, binding of the book could begin at about the end of the year, with first copies of the new Directory available shortly thereafter.

The 19th edition will contain substantially the same type of information as given in the 18th edition, which was published in 1950. One change in content is the dropping of the lists of members of special societies, which deletion will save about 150 pages, allowing enough space to accommodate the listings of an increased number of physicians in the 1955 edition. The individual biographical listings of physicians will, however, continue to indicate membership in the various national medical organizations. To June 30, 1955, biographical data have been added to the Directory records on more than 45,800 new physicians, and approximately 22,000 names have been deleted from the records because of death or other reasons, for a net increase of more than 23,500 physicians. During the same period, more than 222,000 changes of address have been recorded.

The supply of copies of the 1950 edition of the Directory had been exhausted several years ago; therefore, the major source of income for the Directory-Biographical Department during the current period has been the Directory Report Service, a supplementary service furnished to those desiring it on a subscription and service-fee basis. Also, some advance payments have been received for the new edition of the Directory. About 17,000 copies of the Directory will be printed; more than 13,000 subscribers have already placed prepublication orders for the book, which has a list price of $30.00 a copy after publication.

Even though work has not been completed on the 19th edition, plans are being formulated for compilation and production of the 20th edition. With the next Directory tentatively scheduled for publication early in 1958, extensive investigations are currently being made by the Acting Director of the Department to determine the feasibility of producing the book by methods other than linotype composition.

While the efforts of personnel have been concentrated on the task of compiling the Directory, the Department has continued to act as a clearing house of information on physicians for most of the councils, bureaus, and departments of the Association, as well as for other official bodies, government agencies, the medical profession, and the general public. From July 1, 1954, through June 30, 1955, the Department has received an average of 125 telephone calls a day and more than 5,500 mail inquiries concerning physicians during the 12 month period. It is estimated that, during the past year, 12,000 membership applications have been checked for the Secretary's Office, 5,800 license applications have been processed for the Council on Medical Education and Hospitals, and 3,500 applications have been verified for five of the examining boards in a medical specialty. The Department also furnishes the basic information for the I. B. M. card files of physicians maintained for statistical purposes by the Bureau of Medical Economic Research. Personnel of the Membership-Circulation Department refer to the records of the Directory-Biographical Department to identify the remitters of membership dues, to ascertain current addresses, and to verify eligibility to exemption from payment of dues on the basis of postgraduate training, temporary military service, retirement, or attainment of age 70. The Department routinely checks for various headquarters units information on authors, participants in meetings and conferences, prospective advertisers, and other correspondents. Because of the limited personnel available, it has not been possible for the Department to perform some of the services requested by alumni associations, medical societies, and allied organizations during the compilation period of the Directory.

Report of State Journal Advertising Bureau

The State Journal Advertising Bureau, operating under the auspices of the Board of Trustees, functions in behalf of 33 state medical journals, official publications of 37 state medical societies. Organized in 1913, the Bureau secures advertising space sales, handles production details, billing, and collection for the convenience of the journal offices. Helpful suggestions on advertising makeup and comments on economic trends are forwarded to the publications from time to time.

Net sales for the period from July 1, 1954, to June 30, 1955, amount to $736,702.41 as compared with $658,515.16 for the same period of the preceding year and show a gain of 11.87%. A total of 12,423 pages was sold for the 33 journals from July 1, 1954, through June 30, 1955, with an increase of 993 pages over the preceding year's figure of 11,430, a gain of 8.7%.

Because the Bureau functions solely for the benefit of the state medical journals, all money is forwarded to the member publications, after deduction of operating costs of the Bureau. Complete figures are not available at the present date, but charges for 1955 will no doubt approximate last year's of 7.7% of the net sales—a marked difference to the 15% or 25% commission usually charged for selling advertising space without the additional service outlined above.

The Bureau's operative principles provide for a governing board, known as the Advisory Committee, composed of five editors or business managers of state journals who are also members of the American Medical Association. Dr. L. Fernald Foster, Michigan, is chairman of the present committee. The other members are Drs. C. Grenes Cole, Louisiana; Douglas W. Macomber, Colorado; R. G. Mayer, South Dakota; and Wingate M. Johnson, North Carolina. Mr. Alfred J. Jackson, Director of the Bureau, serves as secretary of the Advisory Committee. Ex officio members are Dr. George F. Lull, Secretary and General Manager of the American Medical Association, and Dr. Robert T. Stormont, Chairman of the Advertising Committee and Secretary of the Council on Pharmacy and Chemistry of the Association.

The following 33 official state publications are members of the State Journal Advertising Bureau at the present time:

Journal of the Medical Association of the State of Alabama
Arizona Medicine
Journal of the Arkansas Medical Society
Connecticut State Medical Journal
Delaware State Medical Journal
Medical Annals of the District of Columbia
Journal of the Florida Medical Association
Journal of the Medical Association of Georgia
Hawaii Medical Journal
Journal of the Indiana State Medical Association
Journal of the Iowa State Medical Society
Journal of the Kansas Medical Society
Journal of the Kentucky State Medical Association
Journal of the Louisiana State Medical Society
Journal of the Maine Medical Association
Maryland State Medical Journal
Journal of the Michigan State Medical Society
Minnesota Medicine
Missouri Medicine
Nebraska State Medical Journal
Journal of the Medical Society of New Jersey
North Carolina Medical Journal
Ohio State Medical Journal
Journal of the Oklahoma State Medical Association
Pennsylvania Medical Journal
Rocky Mountain Medical Journal (Colorado, Montana, New Mexico, Utah, and Wyoming)
Journal of the South Carolina Medical Association
South Dakota Journal of Medicine
Journal of the Tennessee State Medical Association
Texas State Journal of Medicine
Virginia Medical Monthly
West Virginia Medical Journal
Wisconsin Medical Journal

Report of Department of Public Relations

The period covered by this report is Oct. 1, 1954, to June 30, 1955. During this nine month period the American Medical Association's public relations program continued to stress positive, constructive activities designed to increase both public and professional understanding of medicine's problems, policies, and goals. Particular emphasis was placed on means of assisting state and county medical societies in the development of effective public relations programs, helping physicians and medical assistants in the improvement of physician-patient relationships, and promoting closer relations between the American Medical Association and its physician members. Special efforts also were made to explain the Association's point of view on reinsurance, veterans' medical care, and other national legislative issues.

Advisory Committee

The Advisory Committee to the Director of Public Relations met three times during the period of this report, offering valuable suggestions on all phases of medical public relations. Present members of the advisory committee are:

Mr. Theodore Wiprud, Chairman
Executive Director and Secretary, Medical Society of the District of Columbia
Mr. James T. Barnes
Executive Secretary, Medical Society of the State of North Carolina
Mr. Merrill C. Smith
Executive Secretary, Nebraska State Medical Association
Mr. Rowland B. Kennedy
Executive Secretary, Mississippi State Medical Association
Mr. James A. Waggener
Executive Secretary, Indiana State Medical Association
Mr. Ralph W. Neill
Executive Secretary, Washington State Medical Association
Mr. Robert D. Potter
Executive Secretary, Medical Society of the County of New York
Dr. John E. Farrell (Sc.D.)
Executive Secretary, Rhode Island Medical Society
Mr. Ralph R. Marshall
Executive Secretary, New Mexico Medical Society

Among the many subjects discussed by or reported to the advisory committee, the following subjects are considered worthy of note.

Public Opinion Survey.—A survey to determine the attitudes of physicians and the general public toward the medical profession and the Association will be conducted by Ben Gaffin and associates in the latter part of 1955. Results of the study, which was being pretested in June, will be revealed at the 1955 Public Relations Conference to be held just prior to the Clinical Meeting in Boston.

Public Relations Conference.—The advisory committee opposed discontinuance of the annual Public Relations Conference but suggested that those attending the 1955 meeting be asked to rate it in terms of program interest and to suggest pertinent topics of discussion for the 1956 program.

Legislation.—A special subcommittee appointed in November, 1954, reported its belief that there is a need for an improved system of reporting the Association's legislative policies to state and county medical societies, and it urged synchronization of all legislative activity with approved public relations practices.

Health Information Foundation Study.—The advisory committee heard a report on the Health Information Foundation's 1955 public opinion survey on medical services and made suggestions on areas for possible inclusion in the study. The department director reported that the American Medical Association and H. I. F. will cooperate closely in releasing the survey results to both the public and the medical profession.

Future Projects.—Reports were made to the advisory committee concerning preliminary planning for the medical profession's cooperation in Farm-City Week, Medical Education Week, high school science fairs, a survey on the qualifications and training of medical assistants, and distribution of a fund-raising film produced by the National Fund for Medical Education.

Press Relations

With the nation's press and public continuing to show an increased interest in all phases of medical news and with the Association itself continually expanding its activities, the department's press relations work likewise increased in volume and scope during this nine month period. In addition to providing a steady flow of scientific information through the weekly news releases, the press section engaged in numerous special activities to publicize the annual and clinical meetings, special conferences and programs sponsored by the Association, and organized medicine's policies on national legislation and other medical issues of public concern.

Annual Meeting.—Press room registration at the Atlantic City meeting exceeded the 1954 San Francisco meeting by 157 to 134 and was second only to the record high of 185 at the 1953 New York meeting. Of the Atlantic City registrants, 81 were newspaper, wire service, or national magazine writers, compared with 66 at San Francisco. The advance packet of 42 news releases was mailed to 86 state and county executive secretaries or press relations men and to 296 science writers, newspapers, and magazines. During the meeting additional releases were written on the Distinguished Service Award, election of officers, and actions of the House of Delegates. The Director of Press Relations made available all resolutions and reports and interpreted House actions to the news writers.

Press conferences for the newsmen were arranged with American Cancer Society officials and others on the smoking-lung cancer question; with Drs. Scheele, Francis, Sabin, and others on poliomyelitis; and with Dr. Salk individually. The Salk conference attracted from 60 to 75 writers, who had been supplied with advance copies of the important Salk text as a result of last-minute efforts by the department and Dr. Salk.

Spot checks of New York and Philadelphia newspapers showed that all of them carried at least one to three stories daily during the meeting, as did Chicago papers. *Time, Newsweek, Ladies' Home Journal, Better Homes and Gardens,* and several other national magazines carried lengthy reports on the meeting, most of them written mainly from releases prepared by this department. After the meeting, roundup stories appeared in several magazines, and many requests for additional material were filled. Special materials were provided for a medical supplement in the *Atlantic City Press,* for several professional magazines, and for the "March of Medicine" telecast.

Clinical Meeting.—The Miami Clinical Meeting was given the same kind of press coverage as the annual meeting but on a smaller scale. Press room registration totaled 31. Advance press packets, containing 22 news releases, were mailed to 81 state and county executive secretaries and to 110 science writers, newspapers, and magazines. Additional releases were written during the meeting on the General Practitioner of the Year award, actions of the House of Delegates, and the Board of Trustees' appointment of the American Medical Association-American Legion Liaison Committee and the Commission to Study Medical Care Plans. Press conferences were set up for the General Practitioner of the Year and for Health, Education, and Welfare Secretary Hobby and Mr. Edwin J. Faulkner, who spoke on the reinsurance issue.

Special Conferences.—The department provided both advance and press room news coverage for the annual conferences that the American Medical Association sponsors on medical education and licensure, industrial health, and rural health. In addition to materials for newspapers and wire services, special mailings and follow-up stories were aimed at publications with a particular interest in the subject matter of each conference. An example of such special handling was the National Conference on Rural Health held in Milwaukee. Advance packets of 10 news releases were mailed to 42 science writers, 183 farm publications, 211 newspaper farm editors, and all Wisconsin papers. During the meeting additional releases and the texts of prepared addresses were made available in the press room. A nine-page, postmeeting summary was sent to members of the Council on Rural Health, its advisory committee, 500 state and county journals and executive secretaries, and 130 farm publications. A roundup story and photo layout were supplied for THE JOURNAL.

Special Releases.—Special news releases were sent to the press concerning the Eisenhower health plan, the report of the Commission on Chronic Illness, the Hoover Commission report, the Salk poliomyelitis vaccine, and other national issues. Special stories also were prepared for newspapers, state and county journals, and THE JOURNAL to help publicize the "Videclinic" and "March of Medicine" television programs.

Weekly News Release.—The weekly news release, averaging from three to five stories based on newsworthy articles or editorials in THE JOURNAL, was sent to approximately 2,000 publications every week except the two weeks of the annual and clinical meetings.

Editorial Survey.—An analysis of 252 newspaper editorials received during the first quarter of 1955 revealed the following results: 127 favorable to American Medical Association policies or the medical profession generally; 45 unfavorable; and 22 neutral or informative. In addition, there were 19 favorable editorials on the chronic illness report and 8 on the American Medical Association survey of men and women patients in hospitals, all written from material sent out by the department. Thirty-one other editorials on general medical subjects dealt mainly with state and local situations.

MAGAZINE RELATIONS

Liaison.—Magazine editors and writers made a total of 162 requests for services ranging from manuscript review to leads for source material. The Assistant Director made special trips to New York City and Washington, D. C., to renew acquaintances in the magazine field and establish new contacts among publications of national circulation. As a result of a personal letter sent to magazine editors and free lance writers, inviting them to cover the 1955 Annual Meeting, 40 magazine representatives registered at the Atlantic City press room.

Magazine-Television Report.—In January, 1955, the department initiated a weekly column in THE JOURNAL summarizing medical articles appearing in mass-circulation magazines and listing forthcoming network television programs of interest to physicians. During the first six months of 1955, the column reported on 202 magazine articles and 60 television programs. Magazines and TV networks have been extremely cooperative in providing advance information for this project.

TELEVISION AND FILMS

Television News.—As a new service to state and county societies with television stations in their areas, the department early in 1955 began distribution of a monthly newsletter that lists network programs in advance, announces aids available to societies producing local programs, and reports news of special interest to societies working with television. A survey conducted in March and announced in April showed that 41 medical societies produce local television shows ranging from regular weekly programs to one-time presentations.

Videclinics.—The department engaged in extensive promotional activities to help build a medical audience for two closed circuit, 90-minute telecasts sponsored by the American Medical Association, local medical societies, and Smith, Kline & French Laboratories. The first Videclinic, held on Feb. 9 and devoted to the subject of coronary artery disease, was beamed to 32 cities. The second, on mental health, was presented on May 9 in 35 cities with the additional sponsorship of the American Psychiatric Association. A total of approximately 40,000 practicing physicians, residents, interns, senior medical students, and others saw the two programs. The department's work, in cooperation with Smith, Kline & French Laboratories, including letters, posters, invitations, announcements, tickets, and postcard reminders, was aimed at medical societies, medical schools, hospitals, and individual physicians and students in the areas of the telecasts.

General Activities.—The department continued to cooperate with the producers, writers, and news directors of various network television shows by providing sources of information and suggesting qualified participants. The department also continued its active efforts to promote both medical and public audiences for the March of Medicine television series and other network shows.

Film Distribution.—A promotional packet was distributed in February to acquaint medical societies with 16 mm. films available from the American Medical Association for showing to schools, clubs, churches, and other lay groups. Motion pictures included in the packet listing were: "A Citizen Participates," "Night Call," "A Life to Save," "Operation Herbert," and "Your Doctor." The last three films on this list also have been made available for showing on television. During the period of this report, an estimated 1,150,000 TV viewers saw "Your Doctor," 6,400,000 saw "Operation Herbert," and 7,200,000 saw "A Life to Save."

LITERATURE DISTRIBUTION

The department distributed a total of 1,259,411 pamphlets, leaflets, manuals, reprints, and other types of literature during the period of this report. Major new pieces written or distributed were: "County Medical Public Relations Manual," which was introduced to the profession at the Miami Public Relations Conference; "What's Up with Our Medical Schools?" which had its introductory mailing in the second quarter of 1955; and "To All My Patients," a leaflet scheduled for direct distribution to individual physicians in the fall of 1955.

SERVICES TO STATE AND COUNTY SOCIETIES

A. M. A. News Notes.—Covering timely items about Association activities and services of benefit to medical societies, nine monthly issues of News Notes were sent to 362 state and county editors, executive secretaries, American Medical Association department heads and guides, and others.

PR Doctor.—Four bimonthly issues of the *PR Doctor* were distributed in the nine month period to give state and county societies news about medical public relations programs in the field and exchange materials demonstrating the actual techniques and materials used. Among the featured subjects were "heartbreak" cases, health fairs, interprofessional relations, telephone directory listings of physicians, a county experiment in health insurance, a state television project and the "County PR Manual." The PR Doctor mailing list now totals approximately 3,700 medical society personnel.

House of Delegates Report.—A roundup story summarizing actions of the House of Delegates and convention highlights was mailed on the final day of both the annual and clinical meetings to delegates, state and county medical editors, and medical society officers and personnel. The mailing list increased from about 650 at the Miami Clinical Meeting to more than 700 at the Atlantic City Annual Meeting.

This Is Your A. M. A.—A revised set of lantern slides with an accompanying speech outline, describing Association activities and services, was distributed to 38 states and Puerto Rico. Eight extra sets have been made available on a loan basis to medical societies, individual physicians, and Association staff members.

Community Health Week.—State societies and approximately 300 county societies were supplied with suggestions and information enabling them to participate in Community Health Week, sponsored by the United States Junior Chamber of Commerce in cooperation with the National Health Council.

Reinsurance Packets.—More than 400 packets of informational material on the reinsurance issue were made up and distributed to 282 county societies, 25 state societies, and 10 members of the American Medical Association Committee on Legislation. The balance of over 80 packets was kept available to fill requests for future use. The purpose of the packets was to enable state and county societies to enlist the support of local newspaper editors, chambers of commerce, and insurance executives.

SERVICES TO COUNCILS, BUREAUS, AND COMMITTEES

Special Conferences.—The department, in addition to the news coverage already described in the Press Relations section of this report, provided stories for THE JOURNAL summarizing the annual conferences on Medical Education and Licensure, Industrial Health, Rural Health, and Medical Care in the Bituminous Coal Mine Area. A JOURNAL editorial on the latter meeting, also written by this department, was reprinted in the *United Mine Workers Journal.* The department also arranged radio and television coverage of the first three of these special conferences. For the Milwaukee Rural Health Conference, as an example, the National Farm and Home Hour originated a 7-minute feature from the meeting; WGN, Chicago, taped one half-hour and 13 5-minute shows; WLS, Chicago, did a live program featuring participants en route to the conference; and Milwaukee stations put on four radio programs and two television shows during the meeting.

Rural Health Digest.—In cooperation with the Council on Rural Health, the department prepared a digest of the 1955 National Conference on Rural Health.

Group Insurance.—In cooperation with the Personnel Department, this department prepared a brochure outlining the Association's new program of hospital, surgical, and medical insurance for employees, including a major medical expense policy.

Editorial Services.—The department provided editorial assistance and public relations counsel to various other departments in Association headquarters in connection with the preparation of literature and the publicizing of reports or projects.

SERVICES TO PRESIDENT AND PRESIDENT-ELECT

The executive assistant assigned to the President and President-Elect carried out the following activities: trips, 17; speeches (research and editorial assistance), 12; advance press releases, 22; press interviews arranged, 25; press conferences arranged, 2; radio and television appearances arranged, 10; and special articles or editorials (research or editorial assistance), 3. He also assisted in the handling of a large volume of correspondence from medical societies, physicians, and the general public.

PRESIDENTIAL INAUGURATION PROGRAM

The department for the third successive year handled all arrangements, promotion, and publicity for the presidential inauguration ceremony at the annual meeting. The 1955 program in Atlantic City, called "Medicine's Proclamation of Faith," was broadcast over the ABC radio network. In addition to the usual promotion and publicity aimed at the general public, the medical profession, and convention registrants, special promotional efforts were made through eastern medical societies and hospitals and Atlantic City area schools, libraries, and churches. As a result, the program in Convention Hall attracted a capacity audience of 5,500. The addresses of Dr. Elmer Hess and Dr. Norman Vincent Peale were reprinted in a pamphlet made available to state and county medical societies.

GENERAL AND MISCELLANEOUS SERVICES

Editorial Services.—In addition to the work done for the President and President-Elect, the department assisted in the preparation of 10 speeches for officers and trustees of the Association. It also provided a number of special articles or editorials for THE JOURNAL, *Today's Health,* and outside publications on such subjects as the Miami Health Fair, the annual meeting, the Tulsa Health Survey, legislative policy, veterans' medical care, American Medical Association-American Legion relations, and dependent medical care.

Daily Bulletin.—The department staff published the Daily Bulletin at the Miami Clinical Meeting and the Atlantic City Annual Meeting.

PR Conference.—The seventh Annual Medical Public Relations Conference, held the day before the opening of the Miami Clinical Meeting, was planned by the department to focus attention on broad public relations problems of special interest to physicians.

Women's Activities.—Two staff members attended the annual meeting of the General Federation of Women's Clubs, distributed 1,400 health program kits prepared by the department, and staffed the American Medical Association exhibit at the meeting.

Exhibits and Kits.—Displays of public relations aids and programs were prepared for the annual meetings of the Louisiana State Medical Society and the American Women in Radio and Television. One hundred kits on the subject of socialized medicine were assembled to answer requests for that type of material.

Medical Assistants.—A department staff member carried out active liaison work with Harold Mickelson on a medical assistants survey; spoke before medical assistants' organizations and maintained contact with state and local groups; provided program planning kits for several state meetings; reviewed a manuscript on medical and dental secretarial duties, and began development of a "PR in Action" kit on the subject of medical assistants.

Guided Tour Program.—The department supervised the guided tour program in the headquarters building, continued refresher courses for present guides, and formulated advance plans for training 20 to 24 new guides in the latter part of 1955.

Secretary's Letter.—The department, as in past years, assisted in the writing and distribution of the Secretary's Letter, which is sent out weekly to approximately 3,500 national, state, and county medical leaders.

Office Plaques.—Distribution of "To All My Patients" plaques during this period brought the total sold to 22,524.

Photography.—Photographic services at the annual and clinical meetings and special conferences were arranged by the department, and prints were supplied for all mediums, organizations, and individuals requesting them.

Mailing Lists.—Department staff members spent considerable time revising and modernizing the mailing lists not only of the Public Relations Department but also of other councils, bureaus, committees, and departments in the headquarters building.

Liaison.—The department Director and the Director of Press Relations attended or spoke at many outside meetings in order to maintain liaison with other national organizations, state and county medical societies, and additional groups.

CONCLUSION

The department wishes to express its appreciation to the House of Delegates and the officers and Board of Trustees of the Association for their cooperation and support during the period of this report. It also thanks the state and county medical societies and the many departments and staff members at Association headquarters who have helped in formulating and carrying out a well-balanced public relations program for the American medical profession.

Report of Washington Office

To a considerable extent the activity of the Washington Office is governed by the interest of Congress in medical legislation. During the first session of the 84th Congress a record number of bills of medical interest was introduced, and hearings on one or more were under way most of the time. Relatively few were enacted into law, but this fact cannot be taken as evidence that Congress is withdrawing from this field. All bills introduced this year remain alive and ready for further congressional action when the second session opens next January. This year also there was a marked increase in medical activities in the executive departments—Veterans Administration, Defense Department, and Department of Health, Education, and Welfare. Complex scientific and technical problems arose in the production of Salk vaccine, and political, social, and financial issues soon were injected into the situation. All added to the work-load of the Washington Office.

Nearly 12,000 bills of all kinds were introduced, all of which were scanned by the Office staff. About 400 were found to be of sufficient medical interest to warrant reporting, the largest number followed in any first session. The Office staff analyzed these medical-interest bills for publication in the weekly Washington Letter and for the benefit of the Committee on Legislation. The Office also obtained more than 7,000 separate copies of bills. Some were sent in bulk to the secretary of the Committee on Legislation for distribution to the committee, and the remainder were mailed to the Chicago headquarters and to others who requested them. Step-by-step congressional action on these selected bills was reported in the Letter. Some hearings lasted weeks and others only one or two days. Each hearing was covered by Washington Office personnel, who also kept track of committee and floor votes, compromises, and other legislative developments. In the case of the more important bills, transcripts of the hearings and the committee reports were examined and additional copies sent to the Committee on Legislation and to other interested parties. As one of the steps in checking on legislation, the Washington Office wrote to the committee handling each bill being followed, requesting that it be informed of hearing dates. As hearings were scheduled, the Chicago headquarters staff and the Committee on Legislation were informed.

Representing the American Medical Association, 17 witnesses testified before congressional committees, and letters giving the official Association position were forwarded to committees in six other cases. The letters generally were prepared by the headquarters staff, then duplicated and forwarded to the appropriate congressional committees by the Washington Office. The witnesses, selected by the Board of Trustees and the Committee on Legislation, usually were briefed by the Washington Office staff prior to their appearance on Capitol Hill.

Because of the heavy load of medical bills under consideration on Capitol Hill, representatives of the Washington Office were in daily contact with congressional committees and committee staffs. By explaining the American Medical Association's point of view, they were able to improve legislation and eliminate many objectionable provisions. This involved personal conferences, telephone calls, and a vast amount of research in medical-social problems. In these technical dealings the Washington Office staff acted in consultation with the Chicago headquarters, the Committee on Legislation, and the Board of Trustees.

The staff was drawn into extensive conferences with congressional committee members and staffs on such diverse subjects as the investigation of narcotics traffic, Jenkins-Keogh legislation, pension plans, flood control, Alaskan mental health, and the Bricker amendment. Considerable time also was spent on the issue of whether optometrists should be held to have the same scientific knowledge as ophthalmologists in determining blindness under social security. Involved in these activities were the supplying of information and discussions of the best approach to the problems. This activity was in addition to the regular exchange of information and viewpoints with congressional sources on the many bills of medical interest taken up by committees.

The course of legislation on Salk vaccine is an example of how the Washington staff operated. The American Medical Association's position, as determined by the Board of Trustees, was that no new law giving the federal government mandatory control over distribution of the vaccine was needed but that the Association had no objection to a federal grant to pay for vaccine for needy families. Originally there was a great deal of agitation for a law to give the United States complete control over distribution and for an unlimited grant to buy vaccine for all eligible groups, whether or not they could afford to pay. American Medical Association witnesses outlined to committees the Association's position. Then, over a period of more than two months, members of the Washington Office staff kept in constant touch with congressional committee staffs and members, furnishing information and explaining the wisdom of the Association's position. At all times Chicago headquarters was kept informed of the developments. During this period the Washington Office maintained contact with the staff and agencies of the Department of Health, Education, and Welfare to give assistance in support of the Association's position. In the end, no new law was enacted for allocation of the vaccine. Instead, the Department of Health, Education, and Welfare was left to allocate the vaccine in a voluntary program that had the support of the pharmacists, the drug manufacturers, and the state health officers, as well as the American Medical Association. The grants law finally enacted set up a $30 million fund for the use of states, with each getting approximately enough to buy vaccine for a third of the children and pregnant women. This issue is not completely settled; the law expires next Feb. 15, before which time Congress will have time to amend the law, appropriate more money, or both.

Following is a brief summary of the session's net results:

Two-Year Extension of the Doctor Draft Act.—The Association opposed the two-year extension of the doctor draft act, and its opposition might explain some of the modifications made in the act. The extension was supported by leaders of both parties, who contrived a legislative situation that made a vote against the doctor draft also a vote against the extension of the regular draft, against the $100 extra pay for military doctors, and against subsistence allowances for service families.

Salk Vaccine.—As noted above, the law enacted regarding Salk vaccine calls for expenditure of $30 million in grants to states, designed to insure that no eligible person is denied inoculation because of inability to pay for the vaccine.

Mental Health Survey.—Congress approved grants for a national survey of mental health problems, a project that has the support of the American Medical Association.

Air Pollution Grants.—Under the air pollution grants program the United States will assist states, communities, and private industry in research on air pollution. This was supported by the American Medical Association.

Commissions for Male Nurses.—Reserve commissions for male nurses in the armed services were authorized.

No other important health legislation was enacted, although several bills passed either the House or the Senate and will be up for final decision during the next session. Included are a proposed national compulsory disability insurance program for covered employees aged 50 and older (passed the House), a plan for United States grants for the construction of research facilities (passed the Senate), and a bill providing construction grants for medical schools. The question of compulsory disability insurance will present the Association with probably its most difficult legislative problem next session. A bill for the commissioning of osteopaths in the medical corps of the military services, which passed the House, was held up in the Senate Armed Services Committee following a letter from the Secretary of the American Medical Association pointing out that the problems involved had not been sufficiently aired at the House hearings.

As more and more bills require the attention of the Association, the Washington Office is made aware of the increasing importance of a close person-to-person contact between the physician back home and the senators and representatives who respect and trust that physician. Specifically, if a congressman has been convinced by his home town doctor that medical legislation must be watched closely, that congressman is more inclined to listen to the American Medical Association's point of view as various bills come up for action. If there is no home town liaison, the congressman often is not too concerned about what the Association thinks. The constant need for an effective doctor-congressman relationship is one of the reasons the Washington Office staff annually attempts to contact state society officials. Last fall Dr. Frank E. Wilson, Washington Office Director, and other staff members covered all parts of the country, explaining national legislative problems at state and regional meetings to which were invited state medical society presidents, executive secretaries, legislative chairmen, and women's auxiliaries and others interested in Washington developments. In addition, staff members, in response to numerous requests, have spoken in many sections of the country to a wide range of organizations interested in medical legislation. Both these and the regional meetings have greatly benefited the staff by informing its members of local opinion and problems.

The Washington Office has another responsibility that has become more important and time-consuming over the last few years. It has grown into an information center on medical matters not only for the medical profession, which is kept up to date on Washington developments through our publications, but also for individual congressmen, congressional committees, national associations, government departments, and representatives of newspapers, wire services, television and radio networks, and magazines. The Library of Congress, as an agent of the Senate and the House of Representatives, continued to call on the Washington Office for information on technical-medical and socioeconomic medical problems. Newspaper correspondents and magazine writers have called on the Office frequently for assistance in gathering factual information. Individual members of Congress request assistance in answering constituents' mail on medical problems. National trade, labor, and fraternal organizations use the Washington Office as a ready source of information in medical problems they encounter. The Embassy staffs call repeatedly for information requested in their own countries. Questions concerning registration of foreign physicians and placement of foreign physicians are frequent. Inquiries into the military service and the doctor draft consumed considerable staff time, as did efforts to assist individual doctors who asked help from the Washington Office in solving their particular problems involving federal departments. In addition, members of the Washington staff worked with the Federal Civil Service Commission in developing a United States employee health insurance program and with the Defense Department in a program to make military medical careers more attractive to physicians. As a phase of this activity, the Washington staff also helped to arrange meetings between representatives of various American Medical Association councils and officials of government departments in an effort to solve problems in which each group had an interest.

As an additional means of helping the profession keep in touch with trends in national legislation, the Washington Office this year inaugurated a Quarterly Legislative Review. The first was published in April and the second in July. In these Special Reports, legislation was evaluated with attention centered on bills that were making progress in Congress. In these Reviews the legislation was described, its current status noted, and its prospects of enactment appraised. Also, the American Medical Association position was given in relation to each bill or each group of bills.

Other Washington Office publications continued as in previous years. New lithographic equipment was purchased this year to speed up processing and to make for efficiency. The weekly Washington Letter was changed to a four-page single-sheet publication, which was expanded to six or eight pages when the volume of bills was heaviest. A concerted effort was made to hold the Letter to four pages most of the time on the assumption that more pages, generally, would be less thoroughly read. A "legislative box score," started in 1954, was continued this year. It showed in tabular form the exact progress to date of the 30 to 40 most important bills being followed by the Washington Office. It was printed in the weekly Letter as legislative developments warranted. There is increasing evidence that in Washington as well as in the states the Letter is recognized as an authoritative, objective report on the federal legislative and departmental developments in medical fields.

To supplement the Letter, 18 Special Reports were issued between September, 1954, and July, 1955. Subjects included the federal medical budget, Hoover Commission medical services, mental health, the Eisenhower health program, complete membership of key congressional committees, the new Hill-Burton regulations, testimony of American Medical Association witnesses, and the Bricker amendment. The Special Report on federal medical spending has been described as the most complete, yet concise, listing of federal medical spending collected and published anywhere. It breaks down into separate spending activities many funds that are lumped into one in the official budget. This was reprinted in full by a number of medical publications and commented on by others. The Special Report on the Bricker amendment also was well received. Its object was to show why the medical profession favors treaty limitation. It was reprinted in full by nine state or regional medical journals and was used as the subject of editorials by others. One state medical society endorsed the distribution of 5,000 copies of this Special Report at a regional fair booth.

The single mailing list that is used for both the weekly Washington Letter and Special Reports presents a growing problem. This service is designed for physicians and others who take a special interest in federal medical legislation. Every two years "sudden death" cards are used in an effort to reduce circulation to those actually interested in the direction taken by federal medical legislation. If the recipient does not return the card by a certain date, his name automatically goes off the mailing list. In the summer of 1953 the mailing list was reduced to about 5,000 by this method. By June, 1955, circulation was past 8,500, approaching the maximum. Another "sudden death" card was sent out in August.

The Month in Washington, inaugurated in December, 1953, was continued as a service to state and regional journals. This three-page report, mailed from Washington on the ninth of every month, is a summary of legislative and administrative developments in Washington. It is so written that it can be published as late as six weeks from the date received. Twenty state and regional journals use the Month in Washington, most of them as a regular feature. It is not supplied to the editors unless they write in and request it. In addition to the use made of the Month in Washington, 27 medical publications regularly reprint material from the Letter and Special Reports. Generally the material is printed intact, but in some cases it is made the basis of editorials.

For five years the Washington Office has been supplying The Journal with a weekly coverage of Washington news, which is carried in the front advertising section. The Office also supplies The Journal with a column devoted to new federal medical legislation.

Report of Committee on Legislation

Although this report would normally cover the period ending June 30, 1955, it is necessary to include the months of July and August to depict accurately the activities of the Committee on Legislation and present a true view of the legislative interests of the Association. It is normal for the closing weeks of a session of Congress to be its most productive period. The first session of the 84th Congress followed this pattern. Only 127 measures became law through June 30, 1955. An additional 236 bills were enacted between that date and the adjournment of the session on Aug. 2, 1955. Presidential action on these later acts was not completed until Aug. 15, 1955. This report, therefore, covers the period from Oct. 1, 1954, through Aug. 31, 1955. During this period the Committee on Legislation has held five meetings, in the course of which it has analyzed 279 new bills embracing 97 major legislative proposals. The Committee has also considered 10 major policy questions not yet introduced as legislation. A policy position on each of these matters has been recommended to the Board of Trustees. On Nov. 29, 1954, Drs. Clark Bailey, Harlan, Ky., and Chauncey L. Palmer, Harrisburg, Pa., were elected to succeed themselves for additional five year terms as members of the Committee.

With the convening of the first session of the 84th Congress in January, 1955, bills of interest to the profession of medicine were introduced at an unprecedented rate. During both sessions of the 83rd Congress, a total of 16,470 bills were introduced. Of that number, 407 bills had medical implications. In the first session of the 84th Congress alone, 11,914 measures were introduced. The Washington Letter reported 403 of these, only 4 less than the total for both sessions of the preceding Congress. The major legislative proposals analyzed by the Committee increased 50% over the preceding year. Divided control of the executive and legislative branches, as well as the discovery by both political parties of the public appeal of health legislation, seems to account for the increased legislative activity. Since 1956 is a presidential election year, indications are that the second session of the 84th Congress, which convenes in January, will be even more active.

First Session, 84th Congress

There follows a chronological list of the measures on which either oral or written statements were presented to the committees or members of Congress, together with the names of the witnesses, a brief résumé of each proposal, a note as to its status at the end of the first session of the 84th Congress, and an indication of the nature of the testimony submitted by the Association. If the bill was enacted, the Public Law number is given. Bills that were still pending at the time of the adjournment of the first session, on Aug. 2, 1955, remain active and may again be considered when the second session convenes in January.

Title VI, H. R. 3458 and Title VI, H. R. 3720.—These two identical omnibus bills, containing six separate titles, form the principal part of the Eisenhower administration's health program. The purpose of Title VI is to amend the Public Health Service Act to authorize a five year program of grants to states for mental health services and to authorize a new five year program of special project grants for the development of improved methods of care, treatment, and rehabilitation of the mentally ill. The position of the Association was one of active support. The interest and activities of the Association in the field of mental health since 1930 was related by Drs. David B. Allman and Leo H. Bartemeier in their testimony on March 10, 1955, before the Subcommittee on Health and Science of the House Committee on Interstate and Foreign Commerce. The scope of the growing problem of mental illness was outlined. Extension of the present program was supported because of the magnitude of the mental health problem and the conviction that the limited federal funds previously expended have been properly handled and have resulted in definite improvement of mental health work in the fields of training, treatment, and rehabilitation. It was emphasized, however, that the position of the Association is limited to support of a temporary federal program in this area, and it was again recommended that the entire question of defining local and federal responsibilities in the public health field be carefully analyzed by the Congress.

These bills remained pending in the Committee on Interstate and Foreign Commerce of the House of Representatives at the close of the first session of the 84th Congress.

H. J. Res. 230.—The stated purpose of this bill was to promote an intensive survey in the field of mental health by authorizing the Surgeon General of the Public Health Service, over a three year period, and, on the recommendation of the National Institute of Mental Health, to make grants totaling $1,250,000 to private, nongovernmental agencies, best qualified by virtue of training and knowledge, for the purpose of conducting a thorough, professional, and impartial study of all aspects of the mental health problem, including methods and practices in diagnosing, treating, and rehabilitating the mentally ill. The committee was informed in the above referred to testimony of March 10, 1955, of the leadership of the American Medical Association, in cooperation with the American Psychiatric Association, in forming the Joint Commission on Mental Illness and Health. The Joint Commission will make a national survey of all aspects of the present status of resources and methods of diagnosing, treating, and caring for the mentally ill and retarded, both within and outside of institutions. It will formulate, on the basis of this survey, a feasible program for the fundamental improvement of methods and facilities for the diagnosis, treatment, and care of the mentally ill and retarded. Dr. Bartemeier explained the hope that such a project might evolve fundamental departures from traditional concepts and methods of dealing with mental illness and thus lead to a far more effective attack on the problem. Inasmuch as this resolution embodies substantially the objective of the Association and outlines a method for financing the activities of the survey while preserving its freedom from federal control, the Association wholeheartedly approved H. J. Res. 230.

At the suggestion of the Secretary of Health, Education, and Welfare, the bill was amended to make it clear that the responsibility for conducting the proposed survey would rest with the organization to which grants were made and not with the Surgeon General of the Public Health Service. A clean bill, H. J. Res. 256, was then introduced, and enacted as Public Law 182, 84th Congress.

H. R. 2967.—The stated purpose of this bill was to provide for strengthening the reserve forces of the armed forces by permitting limited inductions for reserve service with only a six month period of active duty training. In a letter to Representative Overton Brooks, chairman of subcommittee no. 1 of the Committee on Armed Services of the House of Representatives, Dr. George F. Lull, on March 17, 1955, urged the establishment of sound principles in administering such a training program because of the possibility that it would be the foundation on which a system of universal military training could be based. Stating that the Association took no position on the merits of such a system, the letter commented on the medical aspects of the program. The previously established position of the Association in three medical areas was reaffirmed. The letter recommended (a) that individuals whose aptitudes or previous accomplishments indicate that their most effective contribution can be made as a trained professional man should be identified as early as possible and deferred from induction until the completion of their professional education; (b) that current medical care of trainees be provided on the same basis as that furnished to personnel of the armed forces, with consideration of a reduction of the physician-trainee ratio due to the preferred medical risks involved; and (c) that civilian physicians or reserve medical officers be utilized for preinduction, induction, and periodic reserve physical examinations. The Association also expressed unalterable opposition to the extension of Veterans Administration care for non-service-connected conditions in trainees under the proposed program.

After bitter debate over nonmedical features of the bill, H. R. 7000 was substituted and enacted as Public Law 305, 84th Congress, without incorporating the recommendations of the Association.

Title VI, S. 886.—This is the Senate companion bill to H. R. 3458, the administration omnibus health bill that was discussed above. The position and testimony of the Association that were presented by Drs. David B. Allman and Leo H. Bartemeier before the Subcommittee on Health of the Senate Committee on Labor and Public Welfare on March 30, 1955, were identical to those outlined under H. R. 3458.

The bill is still pending before the Senate Committee on Labor and Public Welfare.

S. 724.—The purpose of the bill was to create a government commission to conduct a study similar to that proposed in H. J. Res. 230, discussed above. Because of the preference of the Association for the private study in this area, no position was taken on S. 724. This fact was noted in the testimony presented on March 30, 1955, before the Senate Committee on Labor and Public Welfare.

This bill also remains pending before the Senate Committee on Labor and Public Welfare.

S. J. Res. 46.—This bill is the Senate companion bill to H. J. Res. 230, discussed above. The position and testimony of the Association, which was also presented on March 30, 1955, to the Senate Committee on Labor and Public Welfare were identical to those submitted to the Committee on Interstate and Foreign Commerce of the House of Representatives on H. J. Res. 230.

After hearings on the measure, the Committee on Labor and Public Welfare of the Senate favorably reported the House version, H. J. Res. 256, which was enacted as Public Law 182, 84th Congress.

S. 849.—This measure would amend the Public Health Service Act to authorize 30 million dollars annually for three years for federal matching grants to nonprofit, accredited schools of medicine, dentistry, and osteopathy and to hospitals for the construction of nonfederal research and laboratory facilities. These facilities would be used for research into the cause of a number of chronic and crippling diseases and conditions. Dr. George F. Lull submitted a letter on April 1, 1955, to the Committtee on Labor and Public Welfare of the Senate, indicating that the Association opposed the bill because of the conviction that an emergency of sufficient proportions to justify federal subsidy had not been demonstrated in this broad field. The letter stated that, while the Association is wholly in accord with the desire to improve and expand medical research, it was not felt that the federal construction subsidy proposed would accomplish the purpose. On April 28, 1955, Senator Lister Hill, Chairman of the Senate Committee on Labor and Public Welfare, wrote the Association urging reconsideration of its position, arguing that S. 849 was intended to curtail the existing construction grant program of the Public Health Service and bring it within the purview of the American Medical Association policy on grants-in-aid. Based on this request, the Association position was again reviewed by the Board of Trustees, and on June 6, 1955, Dr. Lull wrote Senator Hill, stating that in the opinion of the Association the measure would be a new and additional program of federal aid, neither supplanting nor requiring coordination with existing programs and that the Association adhered to its original views.

S. 849 was favorably reported by the Committee on Labor and Public Welfare on July 14, 1955, and passed the Senate by a voice vote on July 18, 1955. At the close of the first session of the 84th Congress, it was pending before the Committee on Interstate and Foreign Commerce of the House of Representatives.

Title III, S. 886.—This title of the administration's omnibus health bill would authorize the appropriation of 17 million dollars in gradually increasing annual amounts over a five year period, as grants-in-aid to the states for the vocational training of practical nurses. The federal share of approved projects would be 75% the first and second years and 50% in the remaining three years. The program would be carried out through state boards of vocational education. The position of the Association was one of opposition to the underlying theory of the bill. This position was presented by Dr. Cleon A. Nafe before the Subcommittee on Health of the Committee on Labor and Public Welfare of the Senate on April 14, 1955. The position was taken because of the belief that it was neither necessary nor wise for the federal government to enter the area of state responsibility for vocational education unless an emergency were clearly demonstrated. The Association urged a fact-finding survey.

The bill remains pending before the Senate Committee on Labor and Public Welfare.

S. 929.—The purpose of this bill was to increase the number of practical nurses and auxiliary health personnel by providing federal grants-in-aid to state vocational education programs. The bill would amend the Vocational Education Act to establish a program for training such personnel. State matching funds would be required in 1957, increasing to 50-50 matching in 1959. Although the Association took no action on S. 929, its position of opposition to the principle underlying Title III of S. 886, which was presented on April 14, 1955, to the Senate Labor and Public Welfare Committee, is applicable to this bill also. The committee was so advised.

The bill remains pending in the Senate Committee on Labor and Public Welfare.

H. R. 2847.—This bill would provide a statutory deferment for certain scientific personnel in addition to the provision for deferment at the discretion of the President, which is now contained in the Universal Military Training and Service Act. A person whose capabilities or training marked him as a scientific specialist could apply for deferment, after enlistment or induction, and those selected for deferment would be released from active duty within a 90 day period. On April 19, 1955, in a letter to Representative Paul J. Kilday, the chairman of subcommittee no. 2 of the Committee on Armed Services of the House of Representatives, Dr. George F. Lull reiterated the position of the Association in regard to the deferment from military service of individuals undertaking scientific professional training until such time as they were fully qualified to serve in their professional capacity. The letter recommended that a mechanism other than induction be devised to identify such individuals for deferment, thus eliminating the necessity of a loss of 90 days in their professional training while deferment was under consideration.

H. R. 2847 remains pending before the Committee on Armed Services of the House of Representatives.

S. 890.—This bill was introduced for the purpose of extending the Water Pollution Control Act of 1948 and amending the mechanism for discharging the federal responsibility in this field. Proposed changes in the law included a broadened research authority, which would permit a decentralization of research activities, and authority for using federal grant funds in the overall state control program rather than limiting grants to special categories of activities.

The position of the Association was presented on this bill and on S. 982 by Drs. James R. McVay and J. Lafe Ludwig before the Subcommittee on Flood Control—Rivers and Harbors, of the Committee on Public Works of the Senate on April 25, 1955. The position was one of active approval, recounting that the philosophy of the original act recognized the primary responsibility of the states for the control of water pollution and at the same time provided for federal activity in those areas of primary federal concern. It was stated that, in the light of seven years' experience under the old act, the proposed changes would make for more effective cooperation between the state and federal governments and permit the exercise of greater local initiative in the solution of local problems. It was recommended, however, that provision be made for medical representation on the Water Pollution Control Advisory Board.

S. 890 passed the Senate by a voice vote on June 17, 1955, and was favorably reported by the Committee on Public Works of the House of Representatives on July 26, 1955. It is presently pending on the Union Calendar of the House of Representatives.

S. 928.—Modeled generally after the Water Pollution Control Act, this measure would authorize the Surgeon General of the Public Health Service to adopt programs for eliminating or reducing air pollution. Authorizing a five year appropriation for grants-in-aid to states and to provide individuals and industries, the measure permits the Surgeon General to encourage cooperative activities among political subdivisions and technical research by private industry in combating air pollution. The Public Health Service is also authorized to make investigations and studies and to publish reports thereon. This measure received the active approval of the American Medical Association in the aforementioned testimony of April 25, 1955. The committee was told that further research on the subject and its relation to health is highly desirable and that the proved mechanism of the Water Pollution Control Act, founded on a philosophy recognizing the primary responsibility of state and local governments, was the preferred approach to the subject. A recommendation for the addition of one or more physicians to the Air Pollution Control Advisory Board was made.

S. 928, with minor amendments, was enacted as Public Law 159, 84th Congress.

H. R. 2886.—This measure was an administration bill to extend without substantial change the special draft of older physicians, dentists, and allied specialists for an additional two years beyond its scheduled expiration date of June 30, 1955. When the outbreak of the Korean War in June, 1950, precipitated the immediate need for a large number of physicians in the armed forces to provide medical care for a temporarily increased number of service personnel, the American Medical Association supported the special draft of older physicians, many of whom had received their medical education at the government's expense, as an alternative to the recall to active duty of medical officers who had served long and arduously in World War II. Despite its discriminatory nature, the measure appeared necessary at that time. Subsequent extensions of the law were supported because of a continuation of the original condition. Commencing in 1954, however, there were indications that the Department of Defense was commencing to rely on the special draft as a means of staffing for an indefinite period the military medical services. Several conferences were held with responsible officials of the Department of Defense and the Selective Service System, in an effort to obtain data relating to the legitimate military needs for physicians and the numbers of physicians available for service under the regular draft. Efforts to obtain reliable estimates from military and selective service authorities proved unsuccessful.

On April 29, 1955, Drs. Reuben B. Chrisman Jr. and Edward L. Turner and Mr. C. Joseph Stetler testified before the Committee on Armed Services of the House of Representatives on this bill and H. R. 4645, 84th Congress.

Because of the critical situation in Formosa and the possibility that armed conflict involving the United States might break out momentarily in the Far East, the Association was reluctant to oppose extension of the law actively while the possibility existed that defense officials were in possession of material information bearing on its necessity that could not be divulged for security reasons. The position of the Association, which was presented to the Committee on Armed Services of the House of Representatives, was therefore one of qualified opposition to the extension of the special doctor draft. It was emphasized that, based on information available to the Association, there appeared to be no necessity for its extension. However, recognizing that additional facts might be known to officials of the Department of Defense and the Congress, it was recommended that, should any extension of the law be deemed necessary by the Congress, such extension be limited to a "standby" form of law. The Association specifically recommended that in such an event provision should be made to assure that young physicians having obligations for military service under the regular draft are called by Selective Service before calls are made on older physicians, who have no such obligation for service. It was further recommended that authority to call physicians in Priority III and Priority IV be invoked only by action of the President in time of war or national emergency later declared by the Congress. The committee was informed that both the Health Resources Advisory Committee of the Office of Defense Mobilization and the Task Force on Medical Services of the second Hoover Commission on Organization of the Executive Branch of the Government had recommended against extension of the special draft.

A clean bill, H. R. 5946, including the doctor draft extension, the military medical scholarship proposals of H. R. 4645, and the extension of the $100 monthly special pay, was introduced and favorably reported by the Committee on Armed Services of the House of Representatives. Three days later, on May 5, 1955, to avoid an impending floor fight on the medical scholarship provisions, a new bill, H. R. 6057, was introduced and favorably reported by the Committee on Armed Services. This measure contained only the doctor draft provisions and the extension of special pay. Representative Howard W. Smith, Chairman of the Committee on Rules of the House of Representatives, and other members of the Committee on Rules were not satisfied with the hearings conducted by the Committee on Armed Services. They refused to grant the bill clearance for consideration by the House of Representatives until further information was developed.

On May 28, 1955, Dr. Ernest B. Howard, Assistant Secretary of the American Medical Association, wrote Chairman Smith stating that, since there had now been an opportunity to study carefully the hearings before the Committee on Armed Services, including the justifications offered by the Department of Defense and the Selective Service System for extension of the law, it was apparent that enactment of H. R. 6057 in its present form was unwarranted. Dr. Howard urged that the confusing figures on requirements and availability cited by the Department of Defense and the Selective Service System be carefully reviewed before clearance was granted the bill by the Committee on Rules. Such clearance was never granted, and H. R. 6057 died in the Committee on Rules of the House of Representatives.

The Senate Committee on Armed Services, however, took the unusual action of holding hearings on the measure. The position of the Association having been solidified during the Annual Meeting at Atlantic City, N. J., Dr. Reuben B. Chrisman Jr. testified before the Senate Committee on Armed Services on June 9, 1955. The testimony of Dr. Walter B. Martin, who was unable to leave Atlantic City, was presented by Mr. R. G. Van Buskirk. The Association now opposed extension of the doctor draft law without reservation and pointed out that it was being used as a mechanism to replace career medical officers who were resigning in alarming numbers. Congress was urged to determine the legitimate medical manpower requirements of the armed forces and to provide those needs through the intelligent utilization of civilian physicians and a program designed to make career military service more attractive to experienced physicians.

On June 14, 1955, the Senate Armed Services Committee tacked the doctor draft extension onto H. R. 3005, the bill extending the regular draft, which had previously passed the House of Representatives on Feb. 3, 1955. The amended measure, including the doctor draft extension, passed the Senate by voice on June 16, 1955. Because of the Senate amendment, a conference was necessary. H. R. 3005, containing an amended version of the doctor draft, was reported from conference on June 23, 1955. This amended version reduced the maximum age from 50 years to 45 years and contained a provision exempting from induction special registrants over the age of 35 who had previously applied for commissions as medical or dental officers in one of the armed forces, if they had been rejected solely on the basis of a physical disability. On June 28, 1955, two days before the scheduled expiration of both the regular draft and the doctor draft act, the conference report was called up on the floor of the House of Representatives. After a spirited debate, a motion to recommit the bill to conference was lost on a roll call vote of 221 to 171. Through a parliamentary maneuver, it was necessary for opponents of the doctor draft extension to offer a recommittal motion that appeared to endanger the extension of the regular draft. After failure of the effort to recommit the bill, it was promptly passed by both the House and the Senate and became Public Law 118, 84th Congress.

H. R. 4645.—This bill, considered by the Committee on Armed Services of the House of Representatives in connection with the doctor draft extension, was designed as permanent legislation intended to assist in solving the medical manpower problem of the armed forces by providing scholarships for the professional education of physicians and dentists. Under the bill, scholarship students would agree to accept reserve commissions for a period of eight years and to serve on active duty for a period of either three or four years, exclusive of internship and residency training, depending on the amount of scholarship assistance received.

The American Medical Association, in its testimony of April 29, 1955, before the Armed Services Committee of the House of Representatives, supported the principle of scholarship aid in return for reasonable agreements to render professional service but recommended the incorporation of three safeguards in the program. These were (a) that the student not be approached until he is fully matriculated in the medical school; (b) that the student not expect nor receive special consideration so far as meeting the required standards of scholarship, behavior, and ethics and that failure in these areas shall automatically terminate the scholarship agreement with the student; and (c) that the total number of such scholarship students in any year's class in all of the schools and the number in all of the classes in any single school shall not exceed 5%. It was further stated that, while such a program would expose a large number of young physicians to military medicine as a possible career and to some extent would relieve the necessity for the involuntary service of other doctors, the bill alone was not the answer to the problem of increased resignations of military medical officers. It was urged that extensive efforts be made to make careers in military medicine attractive to physicians.

Although the Committee on Armed Services originally reported a clean bill, H. R. 5946, containing this proposal, that bill was allowed to die, and the measure was returned to the Committee on Armed Services for further study. It appears that this action was taken because of a failure on the part of some members of the committee to understand that the principal purpose of the bill was not to increase the output of physicians by the nation's medical schools but to obtain physicians for the armed services. At the close of the first session of the 84th Congress, the measure remains pending before the Committee on Armed Services of the House of Representatives.

Extension of $100 per Month Special Pay for Physicians and Dentists.—The Administration proposal, which was not introduced as a separate bill, would have limited payment of this special pay after July 1, 1955, to those physicians who agreed to serve periods of active duty in excess of their basic two year liability under the regular draft. The Association warned of the adverse effect on morale that would result if some medical officers were denied the additional pay while others received it. It was urged that the special pay provision be extended without change so that the $100 monthly additional pay would be available to all medical and dental officers. This recommendation was accepted and was contained in both H. R. 5946 and H. R. 6057 when these bills were reported from the Committee on Armed Services of the House. It was incorporated in the form recommended by the Association in H. R. 3005, when the Senate Armed Services Committee tacked the doctor draft extension onto that bill. It was finally enacted with the doctor draft extension as Public Law 118, 84th Congress.

S. 1323.—The stated purpose of this measure is to authorize a five year program of federal grants, on a matching basis, for construction of medical education and research facilities. Grants totaling 50 million dollars annually for the five year period would be authorized. The funds would be used for matching grants to assist public or nonprofit accredited medical schools in the construction, expansion, remodeling, and alteration of teaching and research facilities. Any existing or proposed school could obtain a grant of $25,000 for initial planning. Thereafter, additional grants would be limited to 50% of the cost of construction or alteration at existing schools, and two-thirds of the cost of construction of new schools, except that existing schools could also obtain grants of up to two-thirds of the cost of construction or alteration by giving adequate assurances that freshman enrollment would increase 5% over 1954-1955 figures. Total grants to any school over the period of the law could not exceed 3 million dollars. At the discretion of the school, 20% of the grant for new construction could be allotted to permanent endowment for maintenance of the new facility. Otherwise, the bill provides no funds for operation, salary, or maintenance.

The position of the Association, which was one of approval with suggested modifications, was presented by Drs. F. J. L. Blasingame and Walter S. Wiggins before the Subcommittee on Health of the Committee on Labor and Public Welfare of the Senate on May 6, 1955. It was stated that the House of Delegates on June 13, 1951, had adopted a resolution calling for a one-time federal grant-in-aid, on a matching basis, based on the Hill-Burton Act formula and administrative machinery, for construction, equipment, and renovation of the physical plants of medical schools. Under this resolution no part of the funds could be used in any manner for operational expenses or salaries. It was recommended that two changes be made in the bill. Concern was expressed that the measure would needlessly establish a precedent for urging or inducing medical schools to increase their enrollment more rapidly than justified by their facilities, personnel, and teaching material. The Association expressed its conviction that medical schools would increase enrollment of their own volition as rapidly as possible and recommended that the inducement feature providing a more favorable matching ratio for increased enrollment be eliminated from the bill. It was further recommended that the Federal Council on Medical Educational Facilities, which the measure would establish, include six members selected from among leading medical authorities and that the public members include persons skilled in the broad aspects of engineering, education, finance, and architecture.

At the close of the first session of the 84th Congress, S. 1323 remains pending before the Committee on Labor and Public Welfare of the Senate.

Part E, S. 434.—This bill would in part establish a permanent program of federal subsidy to medical education by paying annually to medical schools sums of $500 or $1,500 for each medical student enrolled. The higher sum would be available on a per capita basis to the extent that the enrollment was increased over the average past enrollment. No local matching of these funds would be required, and it is the purpose of the measure to provide funds for staff and faculty salaries, operation and maintenance of facilities, and acquisition of equipment.

The position of the Association on this measure was one of active opposition. It was presented by Drs. Blasingame and Wiggins to the Subcommttee on Health of the Committee on Labor and Public Welfare of the Senate on May 6, 1955. It was stated that the continuing subsidy, in the form presented, would inevitably lead to undesirable federal regulation of schools of medicine. Further, opposition was expressed to the wide spread between $500 to be paid for each student up to the average past enrollment and the $1,500 to be paid for each additional student, because such a financial premium might induce certain schools to enroll more students than they could properly accommodate. Such a situation would dilute the quality of medical education and be a disservice to the profession and the public.

This measure also remains pending before the Committee on Labor and Public Welfare of the Senate.

S. J. Res. 1.—The "Bricker Resolution," reintroduced in the 84th Congress, is intended to amend the Constitution to prevent the abuse of the treaty power. Recent Supreme Court decisions have made it apparent that treaties and executive agreements may be used to override state constitutions, laws, and customs in areas never before supposed to be proper subjects for federal regulation; to expand the legislative powers of Congress beyond those delegated in the Constitution; and to enact domestic law by means of treaty rather than through the open processes of a representative legislature.

In a letter dated May 16, 1955, to Senator Estes Kefauver, Chairman of the Subcommittee on Constitutional Amendments of the Senate Committee on the Judiciary, Dr. George F. Lull expressed the vigorous endorsement of the American Medical Association of the principle of a constitutional amendment designed to restore to the states and to the Congress those legislative powers that, until recent years, had been thought to be secured to them by the Constitution. It was stated that the Association has no preference as to the language best suited to accomplish this purpose but feels that recent developments make such an amendment vitally necessary. The fact that treaties have actually been ratified by the vote of only one Senator and that executive agreements need not even be submitted to the Senate was pointed out. In addition, the effect of the Italian Treaty of 1948 in altering the medical licensure laws of several states was shown. Finally, the threat to American medicine represented by the myriad conventions adopted by the International Labor Organization and other international organizations was related.

This measure was favorably reported by the subcommittee by a vote of 3 to 2. At the close of the first session of the 84th Congress it remains pending before the Senate Committee on the Judiciary.

S. 1984 and S. 2147.—The general purpose of these two bills, which are somewhat similar, was to authorize the appropriation of federal funds for the purchase and distribution of poliomyelitis vaccine. S. 1984, an administration bill, would authorize an appropriation of 28 million dollars to assist states in establishing a grant-in-aid program for the immunization of children whose parents were unable to pay for the vaccine. S. 2147 would authorize federal appropriations for the purchase and distribution of vaccine for all, regardless of age or ability to pay. Both proposals would require states, as a condition of participation in the federal funds, to present a program, to be administered by a single state agency, providing for the free vaccination of all individuals in certain specified groups designated by the Department of Health, Education, and Welfare.

Dr. Julian P. Price testified on June 15, 1955, before the Committee on Labor and Public Welfare of the Senate, stating that, while the Association was not opposed to S. 1984, it was not in sympathy with the purpose or program included in S. 2147. Dr. Price reported to the committee the resolutions adopted by the House of Delegates at the annual meeting in Atlantic City, N. J., only six days before his testimony. These resolutions disapproved the purchase and distribution of the "Salk polio vaccine" by any agency of the federal government, except for those unable to procure it for themselves, and recommended that federal funds for such a program be allocated to the proper state agencies. Because consideration had been given by the Senate Committee on Labor and Public Welfare to the possibility of legislation providing for allocation and control of the distribution and use of the vaccine, the Association testified against such a program, urging that the Congress allow the vaccine to be produced, distributed, and administered in accordance with the past procedures on any new drug or vaccine.

In the closing days of Congress, a clean bill, S. 2501, was introduced and favorably reported to the Senate. This measure was a compromise between the programs outlined in S. 1984 and S. 2147. In the meantime, the Committee on Interstate and Foreign Commerce of the House of Representatives had reported its own bill, H. R. 6286. When S. 2501 reached the floor of the House, the provisions of the House bill were substituted, and S. 2501 was passed by the House. It was sent to conference, where it was further modified, and on the last day of the first session, Aug. 2, 1955, it was enacted as Public Law 377, 84th Congress. Under the new law, for which 30 million dollars has been appropriated, funds will be allocated to the states in accordance with the states' financial need and the number of unvaccinated children through age 19. Sufficient funds are available to inoculate approximately one-third of the eligible children and one-third of the expectant mothers. If the state program is administered by a public agency, no means test may be applied to determine eligibility for vaccination. This authorization expires in February, 1956, at which time further extension will undoubtedly be considered.

H. R. 4743.—This measure is the House companion bill to S. 1323, 84th Congress, discussed above.

On June 16, 1955, Drs. F. J. L. Blasingame and Walter S. Wiggins testified before the Subcommittee on Health and Science of the Committee on Interstate and Foreign Commerce of the House of Representatives. The position of the Association on H. R. 4743 is the same as that outlined under S. 1323.

The bill is still before the Committee on Interstate and Foreign Commerce of the House of Representatives.

H. R. 9 and H. R. 10.—It is the purpose of these identical bills, sponsored by the American Bar Association, to obtain a tax deferment privilege for the self-employed who desire to set aside a portion of their current income for the creation of voluntary retirement funds. Such a privilege is now available to employees through participation in pension plans sponsored by their employers. Under the proposals, a self-employed individual would be permitted to set aside limited funds annually for a restricted retirement fund. This amount would be exempt from federal income taxes in the year it was earned and placed in the retirement fund, but federal income taxes would be paid after retirement as the money was withdrawn in the form of a pension, probably at a lower rate because of a reduction in income.

Drs. Edwin S. Hamilton and Frank G. Dickinson testified before the Committee on Ways and Means of the House of Representatives on June 27, 1955. The position of the Association, as it has been in past years, was one of active support of the measures. This position is based not only on the fact that simple fairness requires that the self-employed be afforded the same incentive to provide, on a voluntary basis, for their own retirement as is now afforded employed individuals but that the continued maintenance of the private practice of medicine is adversely affected by the many "fringe benefit" opportunities becoming available to the young physician who is willing to forego private practice and enter his profession as a salaried employee.

The Committee on Ways and Means voted 16 to 8 to report out a slightly amended version of H. R. 9 but did not do so before the adjournment of the first session. Consequently, the measures remain pending before the Committee on Ways and Means of the House of Representatives.

H. R. 6286 and H. R. 6287.—These two identical bills are House companion bills to S. 1984, previously discussed.

On June 28, 1955, Dr. George F. Lull wrote to the chairman of the Committee on Interstate and Foreign Commerce of the House of Representatives outlining the position of the Association with regard to the federal role in poliomyelitis vaccination. The views expressed were the same as those presented on S. 1984. On June 21, 1955, Dr. Julian P. Price, representing the American Medical Association, participated in an unusual symposium before the House Committee on Interstate and Foreign Commerce. Leading medical experts were asked to discuss the technical medical aspects of the production and use of the Salk poliomyelitis vaccine for the instruction of members of the committee.

After amendments, including a prohibition against the use of any means test in a state vaccination program utilizing federal funds, H. R. 6286 was favorably reported to the House of Representatives. After the Senate passed S. 2501, the language of the House bill was substituted, as an amendment, for the language of the Senate bill. The House then passed S. 2501. After conference, this measure was enacted as Public Law 377, 84th Congress.

H. R. 483.—This measure would authorize the appointment of osteopaths in the medical corps of the armed forces.

On July 26, 1955, Dr. George F. Lull wrote to Senator Richard B. Russell, Chairman of the Committee on Armed Services of the Senate, outlining the opposition of the American Medical Association to this bill. The position of the Association is based on the belief that the appointment of osteopaths as medical officers will endanger the health and welfare of military personnel, will contribute to the demoralization of career services both in the medical corps and in the line, will endanger the accreditation of residencies and internships in military hospitals, and will unnecessarily hinder the utilization of civilian consultants and other civilian physicians by the armed forces.

After cursory hearings on July 11 and July 12, at which the Department of Defense supported the measure, the bill was favorably reported by the Committee on Armed Services and passed the House on July 18, 1955. It is pending before the Armed Services Committee of the Senate.

H. R. 7225.—In mid-June, 1955, the Democratic majority of the House Committee on Ways and Means, with the approval of the House leadership, agreed to report a bill containing major amendments to the Social Security Act. Since this was largely a political move, it was decided that no public hearings would be held. This bill was introduced on July 11, 1955, favorably reported by the Committee on Ways and Means on July 14, 1955, and passed the House by a roll call vote of 372 to 31 on July 18, 1955. Despite vigorous efforts by the American Medical Association and others to slow down this legislative blitz, the only witnesses heard by the committee were representatives of the Department of Health, Education, and Welfare, who opposed the measure. The committee drew on previous hearings for its information in preparing the bill. This measure, if enacted, would amend the Social Security Act in five important respects. Cash disability benefits would be paid to covered individuals over the age of 50. The test applied would be "inability to engage in any substantial gainful activity by reason of any medically determinable physical or mental impairment which can be expected to result in death or to be of long-continued and indefinite duration." Disability determinations would be made by using the mechanism already established by enactment of the "disability freeze" in 1954.

Under the existing law survivors benefits are paid to children to age 18 and their mothers. The bill continues indefinitely such payments where the child meets the foregoing disability test. The retirement age for women would be lowered from 65 to 62. Coverage of the act would be expanded by including all self-employed persons except doctors of medicine. If the bill becomes law there is slight possibility that physicians will remain exempt from compulsory coverage. The tax on employer and employee would increase by 0.5% each and that on the self-employed by 0.75%, effective Jan. 1, 1956.

To medicine, the disability benefits are the most significant proposal. In addition to injecting the federal government deeply into the practice of medicine at the present time, this step would ultimately lead to the provision of health care to all citizens by the federal government. Because it is a piecemeal approach, rather than a frontal assault, the measure is doubly dangerous.

At the adjournment of the first session of the 84th Congress, H. R. 7225 was pending before the Senate Committee on Finance. Senator Harry F. Byrd, Chairman of that committee, has indicated that extensive hearings on the measure will be held in 1956.

Second Session, 84th Congress

All of the signs point to an unusually active and important session of Congress in 1956. Action can be expected on several matters of prime significance to medicine. Political considerations will weigh heavily in the Presidential election year. It will require diligent effort and wholehearted cooperation by all concerned to protect the interests of medicine and the public during the coming year. In preparation for the period ahead, the Committee on Legislation has undertaken three major projects.

Maps were prepared of each state showing the boundaries of the congressional districts in the state and the names and addresses of the senators and representatives. These maps also contained helpful information and instructions for the most effective communication with congressmen. In August, 1955, each member of the Association was sent a copy of the material pertaining to his state.

The Committee is undertaking to publish and distribute a legislative reference notebook to a limited number of key personnel in the states. This project will permit the accumulation of timely information concerning the background and status of the 10 or 12 most important legislative measures. When further action is taken on a measure, additional material will be prepared for insertion in the notebook and distributed by the Committee.

Finally, in an effort to secure a more complete exchange of information and to improve coordination with state and local medical societies, a series of regional legislative conferences has been scheduled for the fall of 1955. Preliminary registration indicates that attendance at these conferences will be appreciably greater than was experienced in the successful series of conferences held in the spring of 1954. The dates and places of the scheduled conferences are: San Francisco, Sept. 24; Chicago, Oct. 8; Omaha, Oct. 15; New York, Oct. 29; Atlanta, Ga., Nov. 6; and Dallas, Texas, Nov. 19.

Appreciation

In closing its report, the Committee wishes to express again its appreciation to the Board of Trustees, the Washington Office, the Woman's Auxiliary, and the officers and staff of the Association, as well as to the state medical societies, for their cooperation and assistance during the period covered by this report. The Committee particularly wishes to acknowledge the significant contribution of "key legislative personnel" and individual physicians, through whose efforts any measure of success that has been enjoyed is directly attributable.

Report of Law Department

In accordance with the recent change in reporting procedures adopted by the Board of Trustees, this report will cover the period from Aug. 1, 1954, to July 1, 1955. Inasmuch as the Law Department was established only a year ago, this will be the first report of significance that it has been able to provide.

The reorganization of the Department and the coordination of the various legal activities of the Association into a single unit has done much to improve the effectiveness of operations. During the period covered by the report, the Department has been able to continue satisfactorily the medicolegal services rendered by the former Bureau of Legal Medicine and Legislation and has in addition initiated a number of new projects and programs that will be of substantial value to the Association, the medical profession, and the public.

In addition to their regular duties, members of the staff of the Department serve as executive secretaries of the following councils or committees:

Judicial Council, Mr. Edwin J. Holman
Council on Constitution and Bylaws, Mr. George E. Hall
Committee on Legislation, Mr. Richard G. Van Buskirk
Committee on Medicolegal Problems, Mr. C. Joseph Stetler

This arrangement has resulted in the elimination of considerable duplication of effort and a more efficient program for each of the councils and committees involved. In this connection it should be noted that at the present time there are five attorneys in the Department in addition to the Director. The equivalent of two man years are required to provide staff assistance for the aforementioned groups, the most active of which are the Committee on Legislation and the Judicial Council. Inasmuch as separate reports will be filed by each of these councils and committees, no comment will be made here regarding their operations. The Director would like to express sincere thanks and appreciation, however, to the chairman and members of each for the full cooperation and pleasant working relationship that has prevailed.

General Legal Affairs

In conducting the day-to-day operations of an organization as large as the American Medical Association, it is understandable that a number and variety of legal problems are encountered. The Law Department's activities in this sphere include the representation of the Association in matters of a business nature in the same manner that the legal department of any large corporation furnishes legal advice and assistance to those charged with business management functions. The nature of this work most frequently involves the operations of the office of the Secretary and General Manager, the personnel office, the office of the Comptroller, the office of the Business Manager, and the Editor of The Journal.

The Department has rendered opinions on the liability of the Association regarding items intended for publication in the Directory, The Journal, the specialty journals and *Today's Health*. It has examined insurance policies and has prepared revised contracts of all types. Other duties in this field deal with the determination of liability with respect to local, state, and federal taxes. Questions concerning the registration of trade marks and the infringement of copyrights, as well as problems dealing with slander and libel, have also been presented. During the period involved, the Department has been able, through a close working relationship with the office of the Secretary and General Manager, to establish a uniform and systematic method for dealing with the general legal problems of the Association.

Liaison Activities

Shortly after the establishment of the Department, it became obvious that to be of maximum value to the Association it would be necessary to establish a closer liaison with the various permanent councils and committees having offices in the headquarters building. It was decided, therefore, to assign the members of the staff to act in a liaison capacity between those units and the Law Department. The attorneys indicated below, and on occasion the Director of the Law Department, attend the meetings of their particular councils or committees and are charged with responsibility for detecting legal questions involved in future plans or programs. They are also available on a day-to-day basis to answer questions that the members or staff of the council or committee may present. They also assist in the preparation of statements of policy to the extent that legal issues are involved:

Mr. George E. Hall: Committee on Cosmetics; Council on Mental Health; Council on Physical Medicine.

Mr. Bernard D. Hirsh: Council on Medical Education and Hospitals; Council on Industrial Health; Committee on Research.

Mr. Edwin J. Holman, Council on Rural Health, and Council on Medical Service.

Mr. Richard G. Van Buskirk: Council on Foods and Nutrition, and Council on National Defense.

Mr. William J. McAuliffe, Council on Pharmacy and Chemistry, and Committee on Pesticides.

In addition to the permanent councils and committees of the Association, there are a number of temporary committees and subcommittees at all times. Ten of these committees, which have been operating during the period covered by this report, have called on the Law Department for assistance. Either the Director of the Department or a member of the staff has been appointed as a member of the first three committees listed:

Committee on Scientific Councils
Committee on Standing Orders for Nurses
Task Force on Rehabilitation
Committee on Medical Practices
Committee on Medical Care Plans
Cooperating Committee on Graduates of Foreign Medical Schools
Committee on Specialties in Other Fields
Physician-Hospital Relations
Committee on Liaison with Labor and Management
Committee on Grievance Committees

Because of the nature of the work of these committees, the assistance given by the Law Department has in each instance varied considerably. It has been necessary in most instances, however, to participate in a number of committee meetings and answer legal questions that have arisen.

The Director of the Department has operated as a member and as unofficial secretary of the Committee on Scientific Councils and has assisted the chairman in the preparation of agendas and in making arrangements for and preparing minutes following the meeting of this committee. Extensive legal briefs have also been required in connection with the work of this committee. Considerable legal research and the preparation of statements have been involved in connection with the program of the Committee on Standing Orders for Nurses, the Cooperating Committee on Graduates of Foreign Medical Schools, and the Committee on Specialties in Other Fields. A detailed chronological development of certain of the Principles of Medical Ethics as well as a review of pertinent enabling statutes and court decisions has been prepared for the Committee on Medical Care Plans. An extensive study dealing with the disciplinary system of medicine was made and discussed in a paper prepared for the Committee on Medical Practices. This paper was published as part of the committee report that was submitted to the Board of Trustees.

In addition to these liaison activities within the Association, the Department has through correspondence and personal visits established and maintained active contact with the executive secretaries and the legal counsel for the state medical societies. In this way it has on a number of occasions been able to supply legal counsel with background material and pertinent citations in connection with pending or threatened state litigation. Representatives from the Department have on request spoken on medicolegal subjects on at least 30 occasions at state or local meetings. In a number of other instances they have accompanied the Department's exhibit on Professional Liability or The Drunken Driver to state and county meetings.

Although a statistical record is not kept of the number of letters received and answered by the Department, there is no doubt that several thousand are handled in the period of a year. These letters from individual physicians, lawyers, state and county medical societies, and outside organizations deal with a wide variety of problems in the medicolegal field. This correspondence has involved such diverse topics as the procedure for locating missing persons, the requirements for practicing medicine in Italy, and questions of Canon law.

On behalf of members of the Association, the Department has taken up matters affecting their status with government agencies. For example, it was able to achieve some measure of success with the Bureau of Internal Revenue in clarifying the attitude that had previously been taken by certain local collectors relative to whether physicians may ethically and legitimately include business entertainment expenses as deductible tax items.

PREPARATION OR REVIEW OF PUBLISHED MATERIAL

The opportunity to work with the Editor and staff of THE JOURNAL, the specialty journals, and *Today's Health* in preparing special articles, book reviews, and editorials has been welcomed. Assistance has also been provided in reviewing material submitted from other sources that might have legal implications.

With the cooperation of the Editor of THE JOURNAL, a new section entitled Medicine and the Law has been added to the Organization Section of THE JOURNAL. The first article was published on Jan. 1, 1955. From that date until the closing date of this report, 13 items on a variety of medicolegal subjects have appeared. The following list indicates the subjects discussed and the dates of publication:

Income tax article—Business Expense Deductions, Jan. 22, 1955.

Income tax article—Entertainment Expenses, Jan. 29, 1955.

Income tax article—Principal New Provisions of the 1954 Code Affecting Physicians, Feb. 12, 1955.

Income tax article—Tax Aspects of a Medical Partnership, April 2, 1955.

Physicians in Group Practice Held Taxable as Corporation, Jan. 1, 1955.

Rulings of the Judicial Council, Feb. 26, 1955, May 7, 1955, and June 18, 1955.

Selection of Medical Staff in Governmental Hospitals—A Review of the case of Albert v. the Board of Trustees of Gogebic County Public Hospital (67 N.W. [2d] 244), April 9, 1955.

A Current Appraisal of the Medicolegal Aspects of Artificial Insemination, April 30, 1955.

Tax Deductions of Professional Entertainment Expenses, June 18, 1955.

Blood Transfusion—Sale or Service, Aug. 20, 1955.

Hospital Staff Privileges Contingent Upon Membership in County Medical Society, July 23, 1955.

The first four articles have been reproduced in pamphlet form in response to a large number of requests. Since the publication of the last article in this series, approximately 5,000 of these pamphlets have been distributed, primarily to individual physicians. Large numbers of reprints of the other articles have also been distributed.

MAJOR PROJECTS OF MEDICOLEGAL SIGNIFICANCE

Medicolegal Education.—At the request of the Council on Medical Education and Hospitals, members of the staff of the Law Department assisted actively in the formulation of plans for a half-day session in connection with the Annual Congress on Medical Education and Licensure. Two of the members of the staff participated as speakers in a Symposium on Legal Medicine in Undergraduate Medical Education on Feb. 5, 1955.

Establishment of Independent Commissions and Foundations.—The Department has participated in the establishment of new and independent corporate entities involving fields in which the Association has found it desirable to participate jointly with other organizations having comparable interests. For example, programs were outlined and assistance given to outside legal counsel in connection with the establishment of a Joint Commission on Mental Illness and Health and the Blood Foundation.

Study Regarding Medical Expert Testimony.—An increasing number of inquiries have been received from state and county medical societies relative to the establishment of panels of experts to provide medical testimony in personal injury cases and in suits involving professional liability. In an effort to be of assistance in this matter, the Department has conducted a survey to determine which states have such programs in operation. As a result of these inquiries, the Department has been able to assemble the experiences of the states, counties, and cities in which the medical societies and bar associations have worked jointly in this field of endeavor. Although only relatively few areas have engaged in this activity, it is apparent from the correspondence that there is an increasing interest in the establishment of committees to review medical testimony or to establish procedures whereby unbiased expert medical testimony will be available to the courts.

Medicolegal Film Project.—On two occasions during the period covered by this report, representatives of the Law Department met with persons from the American Bar Association, the American Law Student Conference, the Junior Bar Conference, the Association of American Law Schools, the Association of American Medical Colleges, the Student American Medical Association, and the American Academy of Forensic Sciences to discuss the desirability of a joint effort in the production of medicolegal films. It was unanimously agreed by those in attendance that educational films dealing with medicolegal subjects would be of great advantage to practicing physicians and attorneys as well as to medical and legal students. Inquiries are being made at the present time by the aforementioned groups as to whether any of the leading educational foundations are interested in financing a project of this type. It is contemplated that if this program is started, three or four films of 15 to 30 minutes in length should be prepared dealing with such subjects as the doctor as a medical expert witness, medical science in the administration of justice, professional liability, and the role of the physician and the attorney in preparing a case for trial.

Termination of Seal-Acceptance Programs

As a result of a determination by the Board of Trustees and the House of Delegates, the Seal-Acceptance Programs of the scientific councils of the Association were terminated during the past six months. Since that time, each of the councils and committees involved have adopted activities that will be of greater benefit to the medical profession and to the public. In making this transition, it has been necessary for the Law Department to work in close cooperation with all of the scientific councils and committees. Three of the members of the staff of the Department have spent a considerable amount of time in assisting in the formulation of letters of notification to individuals and firms that had previously dealt with the councils under the old program. These members of our staff also assisted in the preparation of statements outlining the new scientific programs.

Study of Professional Liability

In cooperation with the Council on Medical Service, the Law Department, at the request of the Board of Trustees and the House of Delegates, has initiated an extensive survey dealing with professional liability. Within the past several months, a questionnaire was sent to each state insurance commissioner to determine the names of the companies writing professional liability insurance and to ascertain by state the statutes and regulations that affect this type of coverage. In addition, an extensive questionnaire has been prepared and distributed to all of the state medical societies to ascertain the experience that each society has had with group professional liability insurance coverage and claims prevention programs. Personal visits have been made by members of the staff, and other visits will follow, to certain of the state societies that have been most active in this field. It is intended to obtain complete information as to pertinent activities currently being engaged in by medical societies. It will then be possible to analyze, evaluate, and compare existing claims prevention programs, procedures for handling complaints prior to litigation, and the results of professional liability litigation by states. As a later phase of the study, it probably will be necessary, through personal visits and correspondence with insurance companies that formerly wrote and with those who are currently writing this type of coverage, to determine in detail and by geographical areas their experience for the past 5 or 10 years. Information relative to rate increases and variations, the reasons for such changes, differences in claims settlement policies, and the existence of claims prevention programs, as well as the opinion of insurance officials as to future trends and desirable corrective measures, should all be obtained in this stage of the study.

An interim report will be submitted to the Board of Trustees in December. The Department anticipates that another year will be required to prepare the final report, which will clearly indicate the exact, current, national picture concerning the causes of professional liability claims and the availability and the cost of professional liability insurance. More important, it is believed that this data will make it possible to determine the causes for the present situation and why the problem is aggravated in certain areas. It is hoped to formulate, thereafter, a long-range educational program for presentation to both medical and legal professions.

Medical and Legal Relations

The Department has continued, by correspondence and participation, to promote periodic joint meetings between physicians and lawyers at which subjects of mutual interest and concern may be explored. It is apparent that there is a trend toward more frequent meetings of this type. It is believed that this is a healthy development that should be encouraged by national, state, and local medical and legal organizations.

As indicated earlier, members of the staff of the Department have participated actively as speakers in a number of joint meetings of the legal and medical profession. The Law Department, in cooperation with the Committee on Medicolegal Problems, will sponsor three regional medicolegal symposiums on Oct. 9, 16 and 30, 1955, at Chicago, Omaha, and New York City respectively. The response to these meetings has been very gratifying. It is anticipated that over 300 physicians and attorneys will attend each session. Subjects to be covered will be of interest to doctors and lawyers and will include a discussion of recent revisions in the Internal Revenue Code, traumatic neuroses, medical science in the administration of criminal justice, medical expert testimony, trauma and disease, and professional liability. It is hoped that medicolegal meetings of this type can be sponsored annually in the future in cooperation with the American Bar Association. Such joint meetings can be effective in reducing areas of misunderstanding that exist between the medical and legal profession and can do much to assure the proper administration of justice in medicolegal cases.

Medicolegal Abstracts

The Law Department has continued the work of the former Bureau of Legal Medicine and Legislation in preparing abstracts of court decisions in the medicolegal field for publication in The Journal. The fifth volume of abstracts of medicolegal cases containing the abstracts published in The Journal from 1947 to 1952 was published in March of this year. References to a few of the cases abstracted and published during the period of this report are given below.

The Supreme Court of California affirmed a judgment finding that a patient had suffered a partial dislocation of the fourth cervical vertebra as a result of a chiropractic manipulation (*Duprey* v. *Shane,* 249 P. [2d] 8.) The Superior Court of New Jersey, appellate division, held that mere possession of a license to practice medicine, without more, does not render the holder competent to testify in a malpractice case as an expert witness (*Carbone* v. *Warburton,* 91 A. (2d) 518). The Municipal Court of the City of New York, Borough of Manhattan, held that a hospital was entitled to sue an ambulance patient treated in its ward for the fair and reasonable value of surgical services furnished such patient by staff physicians (*Beckman Downtown Hospital* v. *Murphy,* 116 N.Y.S. [2d] 341). The United States Court of Appeals, 10th circuit, held that the federal government is liable under the Tort Claims Act for negligent treatment received by the wife of an enlisted member of the Armed Forces, and a veteran in her own right, while in an Army Hospital (*United States* v. *Gray,* 199 F. [2d] 239).

The Court of Appeals of Kentucky held that, in order for an emergency to negate the necessity for a physician to obtain a consent to an operation, the situation must present a serious condition of immediate peril to the patient's life and health of such a nature that it would be dangerous to wait to obtain the patient's consent (*Labor* v. *Scobee,* 254 S.W. [2d] 474). The Supreme Court of Florida held that a private hospital, even though affected with a public interest, does not become a public corporation just because public funds, amounting to no more than 1% of the hospital's funds, had been contributed to it. The managing authorities still had the sole right to determine who could use its facilities (*West Coast Hospital Association* v. *Hoare,* 64 So. [2d] 293). The Supreme Court of Minnesota laid down the rule relating to the use of medical textbooks in evidence. It held that they could not be admitted as substantive proof of the statements made but that a textbook could be used to discredit the testimony of a witness if the witness stated that he based his opinion, or part of it, on such book or if he stated that such book was accepted as authoritative (*Briggs* v. *Chicago Great Western Railroad Company,* 57 N.W. [2d] 572).

The Supreme Court of Arkansas, in a case involving the leaving of a steel suture in a patient's abdomen after an operation, held that the statute of limitations would not run during any period that a cause of action has been fraudulently concealed by a defendant. Such fraudulent concealment exists when a surgeon fails to use reasonable diligence in discovering the cause of a patient's postoperative pains (*Crassett Health Center* v. *Croswell,* 256 S.W. [2d] 548). The Supreme Court of Iowa limited the occasions on which disinterment may be ordered to those in which the facts show that there is a reasonable likelihood that an autopsy will reveal the cause of death (In re Disinterment of Body of Jarvis, 58 N.W. [2d] 24). The Court of Appeals of New York affirmed disciplinary action against three physicians who had been found, by a federal court, to be in contempt of Congress for ignoring a Congressional subpoena (*Barsky* v. *Board of Regents of University of New York,* 111 N.E. [2d] 222). The Supreme Court of Arizona held that it was a reasonable search and seizure if the force used by officers giving a drunkometer test was only that necessary to enable the officers to capture the defendant's breath after it left his mouth (*State* v. *Berg,* 259 P. [2d] 261). The Supreme Court of Washington overruled prior decisions in that state that had granted immunity to charitable institutions for the negligent acts of its servants committed in the course of rendering services consistent with the charitable purposes of the institution (*Pierce* v. *Yakima Valley Memorial Hospital Association,* 260 P. [2d] 765). The Supreme Court of Idaho held that a naturopath who practices surgery and x-ray diagnosis and who administers antibiotics must be licensed under the medical practice act (*Smith* v. *State Board of Medicine,* 259 P. [2d] 1033). The Supreme Court of California held that the doctrine of *res ipsa loquitur* did not apply to electroshock therapy, because the evidence showed that injuries occur during such therapy even in the complete absence of any negligence (*Farber* v. *Olkan,* 254 P. [2d] 520). The Supreme Court of Appeals of West Virginia held that osteopaths can practice surgery and administer drugs (*Vest* v. *Cobb,* 76 S.W. [2d] 885). The St. Louis Court of Appeals, Missouri, held that osteopaths may practice osteopathy in county hospitals (*Stribling* v. *Jolley,* 253 S.W. [2d] 519).

MODEL POSTMORTEM EXAMINATIONS ACT

In collaboration with the Committee on Medicolegal Problems, the Law Department has worked actively in support of the Model Postmortem Examinations Act, which was drafted and approved by the National Conference of Commissioners on Uniform State Laws. A panel of 12 physicians specially trained in this field was appointed for the purpose of discussing problems relating to the coroner-medical examiner system at medical society meetings. The executive secretaries of the state medical societies were advised of the availability of these speakers in connection with plans for their future state programs.

STATE MEDICAL LEGISLATION

As a result of an opinion survey conducted among the executive secretaries of the state medical societies, it was decided to discontinue the publication of abstracts of bills introduced in state legislatures. Replies received from state medical societies indicated that the efforts of the Association in this regard duplicated the work of the state medical societies and were of no substantial value. The Department has, however, continued to maintain background information and files outlining the experiences of the state societies in certain fields for the benefit of constituent or component medical societies confronted with particular legislative problems.

LITIGATION INVOLVING THE ASSOCIATION

The members of the staff of the Department have worked in close cooperation with the general counsel for the Association in connection with two cases currently pending in which the Association is involved. Assistance has been rendered in the assembling of background information, the taking of depositions, and in other ways in the preparation of these cases for trial.

CONCLUSION

The Department wishes to express its appreciation for the cooperation and assistance it has received from the Board of Trustees and the officers of the Association, from the state and county medical societies, and from allied professional organizations and agencies with which it has worked during the period covered by this report.

Report of Committee on Medicolegal Problems

This report of the Committee on Medicolegal Problems covers the period from Sept. 15, 1954, to June 30, 1955. During that time, the Committee had two meetings at which reports were received from the following subcommittees: Professional Liability, Courses in Medical Jurisprudence, Chemical Tests for Intoxication, Medicolegal Aspects of Blood Transfusions, Blood Grouping Tests, Forensic Pathology, and Forensic Psychiatry.

In cooperation with the Law Department and the Council on Medical Service, the Subcommittee on Professional Liability initiated a comprehensive survey to determine the manner in which professional liability insurance is made available to physicians in the various states, the extent and form of prevention programs, and the trends in liability claims and insurance rates. Information has been received from the state insurance commissioners and has been requested from the state medical societies. Personal contacts will be made by the staff during the next year with selected state medical societies and numerous insurance companies. An interim report on this subject will be submitted to the Board of Trustees in December. It is anticipated that another year will be required to complete the survey and prepare a final report. Ultimately, it is planned to publicize complete information and to formulate a suggested long-range prevention program for the use and guidance of state and county medical societies.

The Subcommittee on Courses in Medical Jurisprudence assisted the Council on Medical Education and Hospitals in planning and presenting a half-day session in connection with the Annual Congress on Medical Education and Licensure. The chairman of this subcommittee, Dr. Louis J. Regan, and the chairman of the full Committee, Dr. Alan R. Moritz, both appeared on the program as speakers at a Symposium on Legal Medicine in Undergraduate Education on Feb. 7.

On April 30, 1955, the Subcommittee on Chemical Tests for Intoxication held a meeting at American Medical Association headquarters, to which outstanding experts in this field were invited. At that time, final plans were made for the preparation of a manual to be used as an authentic means of explaining and interpreting tests for intoxication. The form, size, and outline of the manual were agreed upon, and writing assignments for the various chapters were made. Some chapters have already been submitted and are being edited. The following topics are some of the subjects that will be covered in the manual: importance of intoxication tests; statistics—alcohol and accidents; physiology and pharmacology; interpretation of tests; methods of testing; and medicolegal aspects—court cases, self-incrimination, model legislation, and expert testimony in court.

The Subcommittee on Blood Grouping Tests has followed closely and reported for publication in THE JOURNAL several important recent legal decisions in this field. In addition, the subcommittee has prepared a draft of a supplementary report on the Medicolegal Aspects of Blood Grouping Tests. This material is now being reviewed by the full Committee prior to publication.

MEDICOLEGAL FILM PROJECT

On two occasions meetings were held with representatives from the American Bar Association, the American Law Student Conference, the Junior Bar Conference, the Association of American Law Schools, the Association of American Medical Colleges, the Student American Medical Association, and the American Academy of Forensic Sciences to discuss the desirability of a joint effort in the production of medicolegal films. It was agreed by all of the representatives of these organizations that educational films dealing with medicolegal subjects would be of assistance in training medical and legal students and in postgraduate work for practicing physicians and attorneys. Efforts are now being made to ascertain the best method of financing the production of three or four films dealing with such subjects as the doctor as an expert witness, medical science in the administration of justice, professional liability, and the role of the physician and the attorney in preparing a case for trial.

CORONER-MEDICAL EXAMINER SYSTEM

The Committee has worked actively in support of the model postmortem examinations act drafted and approved by the National Conference of Commissioners on Uniform State Laws. A panel of 12 physicians were selected by the Committee for the purpose of discussing problems relating to the coroner-medical examiner system at medical society meetings. The executive secretaries of the state medical associations have been advised of the availability of these speakers in connection with their future state programs.

SESSION ON LEGAL MEDICINE

The Committee again sponsored and directed a Session on Legal Medicine during the Annual Meeting in Atlantic City in June. The Session, which was held on June 8, included a discussion of the following subjects:

The Mentally Ill Patient: Competence to Consent to Treatment, Contract, Testify, and Make a Valid Will.
Trauma and Cancer.
The Federal Income Tax Law in Relation to Medical Practice.
The Model Post-Mortem Examinations Act.
Human Experimentation: Medicolegal Aspects.
Chinese Immigration and Blood Tests.

MEDICOLEGAL SYMPOSIUMS

Plans have also been completed for three medicolegal symposiums, which will be held this fall in cooperation with the Law Department. These meetings will be held in Chicago, Omaha, and New York City on Oct. 9, 16, and 30 respectively. Advance registrations have already been received from approximately 300 physicians and attorneys for each of these conferences, which will cover subjects of interest to practicing members of both professions. Included on the program will be a discussion of recent revisions in the internal revenue code, traumatic neurosis, medical science in the administration of justice, medical expert testimony, trauma and disease, and professional liability.

DISTRIBUTION OF PAMPHLETS

During the year, the Committee continued the distribution of several leaflets and pamphlets previously prepared by its various subcommittees. During this period, 8,500 copies of a leaflet entitled "Test Your A.Q. (Alcohol Quotient)—Twenty Questions on Alcohol" were distributed. The Committee also continued its cooperative arrangement with the medical schools and distributed 3,500 copies of the pamphlet entitled "Malpractice and the Physician" to graduating medical students. In addition, 800 copies of this pamphlet were distributed to individual physicians on request. Four hundred fifty requests were filled for the pamphlets "Medicolegal Aspects of Blood Transfusion" and "Medicolegal Application of Blood Grouping Tests."

EXHIBITS ON PROFESSIONAL LIABILITY AND INTOXICATION TESTS

The Committee assisted the Bureau of Exhibits in preparing a revised exhibit on professional liability and accompanied it on five occasions at various state and county medical meetings throughout the country. In addition, assistance in showing and explaining the exhibit on chemical tests for intoxication was also provided. This exhibit was shown on 29 occasions.

CONCLUSION

The chairman, members, and staff of the Committee would like to express their appreciation to the Board of Trustees, officers, and members of the House of Delegates for the cooperation and consideration that has been received in carrying out the assignments of the Committee.

Report of Council on Pharmacy and Chemistry

This report covers the activities of the Council during the period from Sept. 1, 1954, to June 30, 1955. The most noteworthy event during this period was the termination of the seal-acceptance program on Feb. 15, 1955. The old program was replaced by a new program of drug evaluation designed to provide a better service to the medical profession.

New drugs have continued to appear on the market at an increasingly rapid rate. Many of these new drugs are extremely useful but not infrequently are capable also of doing more harm than good if administered without due appreciation of their hazards or observance of necessary precautionary measures. The average physician has neither the time nor the facilities to experiment with these new drugs in order to determine their proper indications for use, dosage, possible hazards, and contraindications. He must rely on authoritative sources for this information. The greatest interest in a new drug usually occurs at about the time it is introduced on the market for general use. Newspapers and other lay publications often carry enthusiastic reports on these new therapeutic agents that arouse the interest and hopes of the general public. Sometimes this creates a somewhat embarrassing situation for the physician, who has the difficult task of determining whether or not the administration of a new drug is in the best interests of the individual patient. A calculated risk is involved with the use of drugs that have pharmacological effects of any real significance, and the physician may not share the patient's enthusiasm for trial use of a new and potent drug that has received considerable acclaim in lay publications but little or no mention in scientific medical journals. The primary objective of the new program of operation of the Council is to publish concise, authoritative, opinion reports on new therapeutic agents at the earliest possible opportunity. These reports are based on an evaluation of available pharmacological and clinical evidence.

The old seal-acceptance program of the Council often was too cumbersome and time consuming to permit prompt reports for the information of the medical profession. From Sept. 1, 1954, to Feb. 15, 1955, only 10 new drugs received consideration by the Council. Under the new program of operation 27 new drugs were evaluated in the period from Feb. 15, 1955, to June 30, 1955. In addition, eight additional uses of new drugs, which provide the basis for supplementary reports, were evaluated during this latter period. There is still a backlog of new drugs that have not yet been evaluated by the Council. However, it seems evident that the new program of operation already has proved quite superior to the old one in that it is rendering a more timely and better service to the medical profession. The cooperation of the pharmaceutical industry in getting the new program of drug evaluation under way is most deeply appreciated.

The problem of selecting suitable nonprotected names for new drugs has become increasingly difficult. Many drug firms approach the Council regarding the acceptability of proposed nomenclature for new drugs well in advance of the anticipated time of marketing. Cooperation of this type has often obviated needless changes in labeling or delay in publication of evaluation reports. The Council has come to depend to an increasing extent on consultants in various specialties for advice or assistance in resolving many questions relating to the propriety of new claims for medicinal agents. The valuable services of these consultants has often made it possible for the Council to keep pace with the rapid advances being made in therapeutics and to expedite the drug evaluation procedure.

The regular activities of the Council, including such matters as the evaluation of new drugs and adoption of reports for publication, continue to be conducted through the medium of a biweekly confidential bulletin. However, the annual meeting of the Council provides an opportunity to discuss or review important problems relating to drug therapy, to consider modification or extension of activities and procedures, and to deliberate over the reports received from the various standing committees. Most of the correspondence received in the Council office deals with matters relating to the drug evaluation program and the various publications issued or sponsored by the Council. In addition, several thousand inquiries from practicing physicians pertaining to drugs and therapeutics are answered by the Council office each year. Requests for information relating to particular drugs or therapeutic procedures are also received from numerous lay and professional groups or organizations.

Every effort is made to provide full cooperation with other groups or organizations on matters of mutual interest. Information is regularly exchanged between the Council office and the revision committees of the United States Pharmacopeia and the National Formulary, the Federal Food and Drug Administration, and the United States Public Health Service. Information relating to nomenclature as well as to tests and standards for new drugs is also exchanged with groups or agencies in foreign countries. The program of cooperation with the revision committee of the International Pharmacopeia on the matter of selecting nonprotected names for new drugs has been continued. The Council office is frequently requested by other bureaus or departments at Association headquarters to furnish advice or assistance in matters involving drugs or therapeutics with which they are concerned.

The 1955 edition of New and Nonofficial Remedies, an annual publication of the Council, was ready for distribution in June of this year. Monographs for 41 new drugs were added to the 1955 edition; monographs for 22 drugs were omitted, because these agents were considered sufficiently well known. The 1955 volume will be the last edition of New and Nonofficial Remedies in which descriptions of individual brands and dosage forms appear; this is because of the discontinuance of the acceptance program. However, in other respects, the appearance and content of the book will be altered only slightly. Work on another Council publication, the Epitome of the U. S. P. and N. F., is in progress. This new edition, the 10th, has been designed to supplement New and Nonofficial Remedies even more than in the past because monographs on useful drugs that are no longer in New and Nonofficial Remedies will be somewhat more detailed.

During the past year the Council has authorized publication in The Journal of reports on the following subjects: multiple dose containers for water for injection, U. S. P., and isotonic sodium chloride solution, U. S. P.; new generic and brand names recognized by the Council; misuse of edathamil calcium-disodium for prophylaxis of lead poisoning (a joint report with the Council on Industrial Health); overtreatment dermatitis; spermicidal activity of commercial contraceptive preparations; and drugs intended to alter subjective responses.

Report of Committee on Pesticides

This is the sixth annual report of the Committee on Pesticides. During the past year the following activities were engaged in by the Committee in furtherance of its study program on the health hazards of pesticides.

Educational Activities.—The series of Committee reports reviewing medical and public health aspects of pesticidal chemicals has been extended to 15 with the publication in The Journal of a statement on Abuse of Insecticide Fumigating Devices, and Outlines of Information (Part 1) Agricultural Fungicides. The latter report is the first in a series of outlines of information on pesticides that are to be offered as aids in teaching. The next statement in this series, entitled Outlines of Information (Part 2) Insecticides, has been adopted and is presently waiting publication. Two additional reports, entitled The Present Status of Chlordane and Fatal Chlordane Poisoning, are also awaiting publication. A fifth unpublished report reviewing new developments with pesticides is presently under consideration.

Investigative and Research Projects.—The Committee's willingness to provide information and to arrange for studies of pharmacologically interesting pesticide compounds was reemphasized at the annual meeting of the American Society for Pharmacology and Experimental Therapeutics in April. Several requests for further information on the Committee's role in the arrangement of studies on pesticidal compounds have since been received.

Annual Meeting.—The Committee held its annual meeting on March 2, 1955, at the headquarters of the American Medical Association. Current problems affecting the use of agricultural chemicals and pesticides used in the home were discussed. Certain of the more important topics considered and actions taken thereon by the Committee are set forth below.

Protection of animals as well as plants against insects by means of chemicals that are absorbed and translocated throughout the plant or animal making the host toxic or repellent to attacking pests was emphasized as a pesticide development of growing importance. The propriety of using systemic insect repellents to protect humans against mosquito attacks and of using insecticides in saltlicks to protect animals against insects was questioned by the Committee. It was agreed that a safe and effective method of internal protection against biting and other annoying insects has not been satisfactorily developed.

Although two organic phosphorus compounds are now commercially available as systemic plant protectants, toxicology consideration precludes their use for food crops or forage crops for livestock. It was concluded that, while systemic insecticides offer a new approach, there appears to be no prospect that general control of insects will be practical or widespread in the near future.

Use of insecticides in quarantine was reviewed. The present inflight methods for eradicating insects were considered to be completely inadequate, because no insecticide can be applied in large enough quantity without being hazardous to the occupants of the plane. It was felt that sanitation in and around international airports should be improved in order to maintain successful quarantine.

New chemicals for fly control were discussed in relation to the growing problem of insecticide resistance. Many insect vectors of disease have become resistant to the chlorinated hydrocarbon insecticides. In some areas, this resistance is sufficient to interfere with the control of malaria and other vector borne diseases. The most promising substitutes for the chlorinated hydrocarbons are the organic phosphorus compounds. Concern was expressed, however, over the hazards of repeated exposure to formulations of organic phosphorus compounds.

Service Activities.—The Committee on Pesticides collaborated with other groups and organizations during the past year on problems of mutual concern. It continues to serve as an advisory group to the Interdepartmental Committee on Pest Control. Through the Secretary it also maintained its representation on the Sectional Committee on Common Names for Pesticides of the American Standards Association and on the Liaison Panel of Food Protection Committee of the National Research Council. In conjunction with the Committee on Toxicology, the Committee on Pesticides is sponsoring a symposium on hazardous agricultural poisons and household chemicals at the national meeting of the American Association for the Advancement of Science.

During the past year the Committee was asked by private agencies to consider and render opinion on a variety of medicoeconomic problems involving the hazardous potentialities of pesticides. The Committee exhibit, Accidental Poisoning in Children, and radio transcription, Guarding Against Poisoning, continued to be shown to lay and medical audiences.

Committee on Toxicology

This is the initial report of the Committee on Toxicology. The Committee was established in January, 1955, as a standing committee of the Council on Pharmacy and Chemistry. It has been organized for the express purpose of studying means for decreasing the risks of accidental poisoning. The health problems of detergents; solvents; paint products; art and hobby supplies; cleaning, polishing, and sanitizing agents; caustic and corrosive compounds; and other chemical products employed in and around the home are studied. Toxicity problems involving drugs, cosmetics, and pesticides are considered jointly with American Medical Association groups having programs in these fields.

The Committee is composed of a distinguished group of pediatricians, pharmacologists, and regulatory officials. They advise the Committee's headquarters staff in the administration of a five point study program to (1) promote informative labeling and safe packaging, (2) encourage laboratory and clinical research for antidotes, (3) standardize technical nomenclature, (4) develop criteria for evaluating hazardous substances, and (5) sponsor a sustained educational program. Several basic steps have already been undertaken, including a survey of trade names and composition of widely used chemical products, expansion of its medical registry of poisoning cases, and sponsorship of a

Conference on Health Problems of Household Chemicals attended by representatives of government, industry, and medicine.

The Committee makes its findings available to physicians and the public through the medium of status reports and editorials, exhibits, radio transcriptions, and an inquiry service. Two status reports, entitled Candy Medication and Accidental Poisoning and Precautions Regarding Salicylates, Including Aspirin, and several editorials have been published in THE JOURNAL. The Committee, in collaboration with the Committee on Pesticides, is making arrangements for a symposium on the health hazards of chemical products at the Atlanta meeting of the American Association for the Advancement of Science.

The program of the Committee on Toxicology is intended primarily to offer guidance and to stimulate awareness in physicians and consumers of the health hazards attending careless or injudicious use of chemical products. It is believed that this program will produce an improved public attitude toward these materials.

COMMITTEE ON RESEARCH

The Committee on Research has moved forward in consolidating its operations during the past year. A great deal of effort has been put into the clarification of its various functions and into the strengthening of the organization of the Committee as a whole. The possible expansion of the activities of the Committee on Research to provide grants-in-aid for educational purposes has been proposed and is now receiving consideration.

The Committee has given some thought to the matter of sponsoring the presentation of basic medical science reviews in THE JOURNAL. Such reviews would call to the attention of physicians important advances in the basic preclinical disciplines. The Committee would also solicit original articles in different fields of research from distinguished investigators. Such manuscripts would be screened by the Committee's editorial group, and the material selected would be transmitted to the Editor of THE JOURNAL. The Committee would also sponsor the extension of a feature similar to the Clinical Pathological Conference and the Therapeutic Conference. It is hoped that these proposals will enhance the value of THE JOURNAL as a medium for additional postgraduate training and continuation study for physicians.

COOPERATIVE INVESTIGATION

As in the past, the Committee on Research is continuing its activities in the field of cooperative investigation. The basic principle on which this type of enterprise was initiated is still applicable. A concerted effort is made to assemble information from investigators in a field in which no one investigator has a group of cases sufficiently large to yield statistically valid data. This approach permits the Committee to accumulate these data, to evaluate them, and to publish the results as a study if found to be valid and of statistical significance. When a cooperative investigation of this sort is undertaken, a group of experts in the particular field are brought together to consider the matter. These symposiums have established criteria of admissibility of cases to the study and specific schedules of treatment to be followed by the investigators in the clinics. All of the drugs administered in such studies have been donated by pharmaceutical manufacturers. Funds for the cost of administration of these programs are furnished by the American Medical Association. The individual investigator receives no compensation for his service, but this does not preclude his requesting funds for the study from the Subcommittee on Grants-in-Aid of the Committee on Research or from an outside agency. A report is prepared by the group involved in the study, which is reviewed by the sponsoring subcommittee and the Committee on Research. If the report is found worthy of publication, it is transmitted to the Council on Pharmacy and Chemistry with a recommendation that it be published in THE JOURNAL.

Steroids and Hormones in Mammary Cancer.—The study group on cancer met in the spring to review the progress made in the study of mammary cancer. It was agreed that, because of the length of time this study has consumed, it should be terminated on June 30, 1956. The study group completed arrangements for the collection of data on cases of mammary cancer treated by adrenalectomy or hypophysectomy. It is hoped that through this means the study group will be able to assemble data on several hundred cases of mammary cancer in which adrenalectomy was done.

Pregnancy Complicated by Diabetes Mellitus.—A group of investigators will study the influence of hormones on pregnancy complicated by diabetes mellitus. The study has just begun, with 10 clinics observing the effects of the hormones and another 10 clinics acting as controls. In addition to information concerning the diabetic mother, the investigators will submit information about the delivery, the newborn child, and the placental tissue. It is anticipated that this study will run for two years and that the data collected by the Committee will form the basis of a report that will be published in THE JOURNAL.

Hypertension and Hypotensive Agents.—A conference was held to consider the problem of hypertension and hypertensive agents. A group of investigators were assembled, and an organization was formed with a cardiologist as chairman. The group directed one of its members to prepare a statement of classification of hypertension. When this classification has been prepared, consideration will be given to the matter of evaluating hypotensive agents. A suitable form for the reporting of such data will be developed when the group reaches the decision to go forward with the investigation in collaborating clinics.

Registry of Blood Dyscrasias.—The subcommittee on registry of blood dyscrasias has been functioning for a relatively brief period, and the 70 clinics collaborating in the study have been most cooperative. The subcommittee has considered a number of problems and assembled some information on four new drugs. No formal report has been prepared since the work has not been completed; however, this information was circulated among the investigators to acquaint them with the findings. During the year, the Committee received a number of reports of adverse reactions from one drug. The secretary met with representatives of the manufacturer, and a plan of cooperation was worked out. The firm is now submitting reports to the Committee of all adverse reactions brought to its attention concerning their product. A proposed statement has been prepared by the Subcommittee on Blood Dyscrasias dealing with the toxic potential of the drug and the need for adequate warnings. As soon as this proposed statement has been approved, it will be incorporated in a monograph report and published in THE JOURNAL.

Conference on Adverse Reactions.—A new investigating group is being considered as the result of a recommendation made at the 1954 annual meeting of the Council on Pharmacy and Chemistry. The Committee on Research is in the process of bringing together a group of experts in a number of fields of medicine with a view toward the possible development of a subcommittee on adverse reactions, whose function will be to formalize a registry and to develop a report form applicable to such an operation. The outcome of this meeting will be reported next year.

EDUCATIONAL AND INFORMATIONAL PROJECTS

During the past year the Committee on Research has sponsored a number of informational projects. A report on Therapeutic Alterations of Steroid Metabolism in Advanced Mammary Cancer was published in THE JOURNAL, Dec. 25, 1954. In 1952, a questionnaire dealing with the research activities of physicians was sent to 11,340 medical men throughout the country, and in 1954 a similar questionnaire was submitted to 773 Illinois physicians. At the present time, the results of these surveys are being compared, and it is anticipated that a report will be ready for publication shortly.

GRANTS-IN-AID

The Subcommittee on Grants-in-Aid undertakes the consideration of requests for funds for research. Funds made available by the American Medical Association are awarded for the investigation of drugs and other agents used in the diagnosis, treatment, and prevention of disease. Funds provided by the William Volker Foundation and administered by the subcommittee under the designation of the William Volker Fund are used in sponsoring research in the basic medical sciences. A record of all grants-in-aid made under the auspices of the former Therapeutic Research

Committee and those made under the auspices of the Subcommittee on Grants-in-Aid is on file in the Committee office, where it is available for review.

The Subcommittee on Grants-in-Aid of the Committee on Research has approved the following grants since Jan. 1, 1955:

Grant 140, $500 to Dr. Herman C. B. Denber, Manhattan State Hospital, for studies on Mescaline: Its action on the clinical and brain wave patterns of epileptic patients.

Grant 142, $500 to Dr. Milton Huppert, University of North Carolina, to study the effect of preparations of fatty acids and parabens against *Candida albicans*.

Grant 143, $500 to Dr. Bruce W. Halstead, College of Medical Evangelists, for investigation on the physiological effects of ichthyosarcotoxins.

Grant 144, $1,000 to Dr. Irving Young, Wayne University, for the evaluation, development, and applications of paper electrophoresis in clinical problems.

Grant 145, $500 to Dr. Roland H. Alden, University of Tennessee Medical Units, to study the preparation, yield, and biological activity of estrogen sensitized collodian particles.

Grant 146, $492 to Dr. Richard S. Webb Jr., University of Illinois, to study the role of biliary-intestinal reflux in the production of infection and stricture at the site of choledochoduodenostomy.

Grant 147, $300 to Dr. Jay A. Smith, the Chicago Medical School, to study the bronchoconstrictor effects of thiamine.

Grant 148, $500 to Dr. William John Griffiths Jr., the University of Mississippi, to study the psychobiological differences between animals resistant to and susceptible to breakdown under stress.

Grant 149, $400 to Dr. Arne Schairer, Stritch School of Medicine of Loyola University, for the study of canine homologous fascia lata grafts to diaphragmatic defects.

Grant 150, $500 to Dr. Gordon E. Gibbs, University of Nebraska, for the determination of pancreatic function in the newborn infant.

Grant 151, $475 to Dr. William H. Boyce, Wake Forest College, to study proteins and other biocolloids of urine in health and in patients with urinary calculous disease.

Grant 152, $250 to Dr. Robert H. Pudenz, Institute of Medical Research, Huntington Memorial Hospital, to study tumors induced in animals by embedding various plastics.

Grant 153, $500 to Dr. Kurt Lange, New York Medical College, to study the usefulness of experimental nephrotoxic nephritis and nephrosis as a yardstick for specific therapy.

Grant 154, $500 to Dr. John R. Goldsmith, University of Washington, to study the maximum expiratory flow as a pulmonary function test.

Grant 155, $500 to Dr. Victor J. Cabelli, University of Missouri, to study the in vitro and in vivo sensitivity of chromogenic acid-fast organisms to antibiotics and chemotherapeutic agents.

Grant 156, $500 to Dr. Charles M. Carpenter, University of California, for studies on the desensitization of guinea pigs with experimental brucellosis employing various chemical fractions and extracts obtained from Brucella.

Grant 157, $500 to Dr. T. S. Danowski, University of Pittsburgh, for a study of therapy of recurrent nephrotic syndrome.

Grant 158, $350 to Dr. James M. Dille, University of Washington, to study the photofluorometric determination of alkaloid drugs.

Grant 159, $500 to Dr. Charles M. Gruber, College of Medical Evangelists, to study (1) the effects of pharmacological agents and inorganic ions on drug induced cardiac arrhythmias and (2) the effects of apomorphine on the gastrointestinal system.

Grant 160, $500 to Dr. Kenneth F. Lampe, University of Miami, to study the qualitative chemical identification of synthetic analgesics.

Grant 161, $500 to Dr. Don W. Micks, University of Texas, to study the therapeutic effects of a blood derivative, Sanguinin, on the healing of wounds.

Grant 162, $500 to Dr. Terrell C. Myers, University of Illinois, to study the phosphonate analogues of intermediates of glycolysis.

Grant 163, $500 to Dr. Hugh J. Phillips, the Creighton University, to study the separation of urinary gonadotropins.

Grant 164, $500 to Dr. Richard H. Saunders, University of Vermont, to study the alkaline phosphatase content of granulocytes of perpiheral blood in patients with hematological disorders of malignancy.

Grant 165, $500 to Dr. Gordon W. Searle, State University of Iowa, for the study of bile salts; their usefulness for intestinal fat absorption versus their toxic effects.

Grant 166, $500 to Dr. Paul W. Smith, the University of Oklahoma, to study the influence of ethylenediamine tetraacetic acid on calcium ion distribution in digitalis toxicity.

Grant 167, $500 to Dr. Walter F. Watts, Loyola University, to study the effect of different radio-opaque solutions on the fallopian tubes.

Grant 168, $500 to Dr. Clarence Dennis, State University of New York, for the study of cardiovascular surgery.

Grant 169, $250 to Dr. William Havener, Ohio State University, for the evaluation of antrenyl and related drugs as fungistatic agents.

Grant 170, $500 to Dr. L. Rubenstein, Michael Reese Hospital, for the study of a substitute esophagus.

Grant 171, $500 to University of Louisville, for the studies of, (1) cycloserine in experimental tularemia, comparative studies of antibiotics in tularemia, Dr. S. Stephen Chapman; (2) effects of metacortandracin on serum lipids, Dr. B. J. McIntosh; (3) effect of carbon tetrachloride on renal function, Dr. Charles H. Duncan; (4) the transport of radioactive inorganic phosphate by the pulmonary circulation in pulmonary edema, Dr. James C. Moore.

Grant 172, $250 to Dr. Walter C. Hess, Georgetown University, to study the stimulation of liver glycogen production by cortisone, hydrocortisone, and amino acids.

Grant 173, $400 to Dr. Irving G. Pesek, Loyola University, for the study of repair of diaphragmatic defects with polyvinyl sponge in dogs.

Grant 174, $500 to Dr. James F. Bosma, University of Utah, to study the pharmacological modification of hyperkinesis in brain-damaged children.

Grant 175, $500 to Dr. Miriam E. Simpson and Gertrude van Wagenen, University of California, to study the effect of gonadotropins in immature male and female Macaca mulatta.

Grants from the William Volker Fund

William Volker Grant 30, $500 to Dr. Samuel P. Bessman, University of Maryland, to study the mechanism and treatment of hepatic coma.
